EBULLITION, in *Chemiſtry*, &c. is uſed for a violent inteſtine motion, or colluctation of parts, occaſioned by the mixture of ſalts of different natures.

Dr. Harris will have it properly and immediately, to ſignify that particular ſtruggle or effervescence, ariſing upon the mingling together of an acid and alcaliſate liquor.

Mr. Boyle has an experiment to ſhew, that a conſiderable *ebullition* may be produced by ſuch a mixture, without the bodies acquiring any heat; nay, that a degree of cold may be produced with it, greater than was in either of the bodies ſingly, though accompanied with a great ſtruggle, tumult, noiſe, and froth. For, having ſhook one part of oil of vitriol into twelve parts of common water, the mixture was at firſt ſenſibly warm; then the ball of a thermometer was placed in it, till the included ſpirit had gained the temperament of the mixture: but then a convenient quantity of volatile ſalt of ſal armoniac being gradually put in to ſatiate the acid ſpirits of the mixture, the ſpirit in the thermometer deſcended above an inch.

EBULUS, the *dwarf-elder*, in *Medicine*. This is a troubleſome weed in many of our fields, and called, danewort, and walwort. The leaves may be diſtinguiſhed from thoſe of the elder-tree, by their having nine, eleven, or thirteen lobes to each leaf, which are long, narrow, and very ſlightly indented on their edges; whereas the leaves of the common elder have ſeldom more than five, which are broader and ſhorter. The roots and leaves of dwarf-

elder are faid to be both cathartics. The juice of this plant has been recommended in the dropfy, gout, and fcorbutic diforders. The flowers are eſteemed fudorific; and the leaves boiled till perfectly ſoft, make a good cataplaſm for the *ſtomach*. See ELDER.

EBUR, *foſſile*, in *Natural Hiſtory*. See *Foſſile* IVORY.

EBUR *foſſile variegatum*, in the *Natural Hiſtory* of the ancients, a name given to the ſubſtance which we now call the rough or native turquoiſe.

Foſſile ivory, and the bones of other animals, are frequently found buried at great depths in the earth, and are found to have preſerved their ſubſtance, texture, and colour in different degrees, according to the nature of the matter they happen to have lain among. Sometimes they are firm and ſolid, and ſcarce altered in colour; and ſometimes more or leſs hardened, and tinged to different colours by the different matters in which they have been depoſited.

Of this kind was the ſpotted foſſile ivory of the ancients, which was in all reſpects the ſame with our rough turquoiſes of many places, which are no other than the teeth and bones of animals accidentally lodged in the way of particles of copper. See TURCOIS.

ECACOATE, in *Zoology*, a name by which the natives of ſome parts of America call the *Rattle-*SNAKE.

ECALESIA, *Exaleſia*, in *Antiquity*, a feſtival kept in honour of Jupiter, ſurnamed *Hecalus*, or *Hecaleſius*, from *Hecale*, one of the borough-towns in Attica.

ECARTELE, in *Heraldry*. See QUARTERLY.

ECASTOR, in *Antiquity*, an oath wherein Caſtor was invoked. It was a cuſtom for the men never to ſwear by Caſtor, nor the women by Pollux.

ECATESIA, *Exateſia*, in *Antiquity*, an anniverſary ſolemnity, obſerved by the Stratonicenſians, in honour of Hecate.

The Athenians likewiſe had a public entertainment, or ſupper, every new moon in honour of the ſame goddeſs. The ſupper was provided at the charge of the richer ſort; and was no ſooner brought to the accuſtomed place, but the poor people carried all off, giving out, that Hecate had devoured it. For the reſt of the ceremonies obſerved on this occaſion, ſee Pott. Arch. Græc. lib. ii. cap. 20.

ECATÆA, *Exateia*, in *Antiquity*, ſtatues erected to the goddeſs Hecate, for whom the Athenians had a great veneration, believing that ſhe was the overſeer of their families, and that ſhe protected their children. Pott. Arch. Græc. lib. ii. cap. 20. tom. i. p. 386.

ECATOMBÆON, *Εκατομβαιων*, in *Chronology*, the firſt month of the Athenian year. It conſiſted of thirty days, and began on the firſt new moon after the ſummer ſolſtice, and conſequently anſwered to the latter part of our June and beginning of July. The Boeotians called it *Hippodromus*, and the Macedonians *Lous*. See MONTH.

The word is a derivative from the Greek *εκατομβη, a hecatomb*, becauſe of the great number of hecatombs ſacrificed in it.

ECAVESSADE, in the *Manage*, is uſed for a jerk of the caveſſon.

ECBASIS, *Εκβασις*, in *Rhetoric*, is uſed for a digreſſion.

ECBOLE, *Εκβολη*, in *Rhetoric*, is alſo uſed for a digreſſion.

ECBOLICS, *ecbolica*, from *εκβαλλω, I eject*, in the writings of the ancient phyſicians, a term uſed to expreſs ſuch medicines as were given to promote delivery in childbirth; and alſo ſuch as cauſed abortion. See DELIVERY.

ECBRASMATA, from *εκβραζω, I cauſe heat*, in the writings of ſome of the earlier phyſicians, a word uſed to expreſs eruptions, or puſtules, of a fiery and inflamed nature, appearing on different parts of the body. Virgil calls theſe *ardentes populas*, and ſeems to attribute them to the wearing cloaths made of the wool of ſheep which had died of a murrain, which he deſcribes.

ECBRYSOMATA, from *εκβυω, I cauſe to ſpread*, a word uſed by Galen, and the old phyſicians, for thoſe eminences or protuberances of the bones at the joints, which appear through the ſkin.

ECCANTHIS, or ENCANTHIS, in *Medicine*. See ENCANTHIS.

ECCATHARTICS, a name given by different writers in *Medicine*, to medicines of different kinds, and producing very different effects. See CATHARTICS.

ECCE-HOMO, among *Painters*, a name given to a picture, wherein our Saviour is repreſented in a purple robe, with a crown on his head, and a reed in his hand, ſuch as he was preſented before Pilate by the Jews.

The phraſe is Latin, borrowed from the words of the Jews themſelves; q. d. this is the man.

ECCENTRIC. See EXCENTRIC.

ECCENTRICITY. See EXCENTRICITY.

ECCHYMOSIS, *Εκχυμωσις*, the effuſion of blood from a rupture in ſome of the ſmall veins near the ſkin, cauſing a livid or blue neſs thereof.

This is alſo called *ecchymoma*, *εκχυμωμα*, and ſtands diſtinguiſhed from the *enchimoſis*, where there is no extravaſation.

The *ecchymoſis* is either *ſimple*, or with *abſceſs*. The former is a mere diſeaſe of the ſkin, wherein the blood extravaſated by ſome blow, or contuſion, upon its arrival between the fleſhy or muſcular parts and the cutis, ſtops there, and turns black or livid, without any appearance of a wound. In the latter, the extravaſated blood ſuppurates, and breeds an impoſthume.

An *ecchymoſis*, or extravaſation of blood under the ſkin, is an accident too common, after bleeding in the arm. This ſometimes is ſo violent in degree, that the arm after ſwelling and becoming black and blue, is violently inflamed, with acute pain, and either a ſuppuration or beginning mortification. This accident frequently happens from the vein's having been cut quite aſunder in the operation, but often by the patient's uſing the arm too ſoon after bleeding, in violent and long exerciſes, in which the contractions of the muſcles make the veins ſwell, and force their blood through the orifice into the interſtices between the fleſh and ſkin.

In ſlight accidents of this kind there is no danger, the ſtagnating blood being eaſily diſperſed by a compreſs dipped in vinegar and ſalt, or in ſpirit of wine. And ſometimes it ſuppurates, and, making its way through the integuments, becomes naturally diſcharged, and the wound will heal with a diachylon plaſter. But where the quantity of extravaſated blood is large, there is no hope of its being diſperſed ſo eaſily, but the diſorder generally terminates in an abſceſs or gangrene. To prevent theſe accidents, the ſurgeon's buſineſs is to clear off the livid parts, and apply warm fomentations. Heiſter's Surgery, p. 285.

ECCLESIA, a Latin, or rather Greek term, ſignifying CHURCH.

In our ancient law-books, Fitzherbert obſerves, that ECCLESIA, *Exaleſia*, properly ſignifies a *parſonage*. Whence, if a preſentation were made to a chapel, as to a church, by the name of *eccleſia*, it changed the name thereof, and it preſently commenced a church.

When the queſtion was, Whether it were *eccleſia, aut capella pertinens ad eccleſiam?* the iſſue was, Whether it had *baptiſterium & ſepulturam?* For if it had the adminiſtration of the ſacraments and ſepulture, it was in law judged a church. See CHAPEL.

ECCLESIA, *Reſtitutiones extractæ ab*. See RESTITUTIONE.

ECCLESIA, *Rotto de ecclesiarum*. See RECTO.

ECCLESIA, *Warda*. See WARDA.

ECCLESIA *ſculptura*, the image or ſculpture of a church in ancient times was often cut out in plate or other metal and preſerved as a religious treaſure or relique; and to perpetuate the memory of ſome famous churches.

ECCLESIANS, ECCLESIANI, in *Church Hiſtory*. Upon any falling out, or miſunderſtanding, between the emperors and the churchmen, the adherents to the emperor called ſuch as adhered to the intereſts of the church and churchmen, *eccleſiani*, a term of reproach, anſwering to our high-church men.

ECCLESIASTES, one of the books of the Old Teſtament; thus called, by a Greek word, ſignifying *preacher*; becauſe the author in it declaims, or *preaches*, againſt the vices and vanities of the world.

This is Mariana's judgment: Grotius thinks otherwiſe; taking the book to derive its appellation from its being a collection of fine ſentences and reflections on the vanity of the things of our earth, &c. from the word קהל, which ſignifies to *aſſemble*, or *collect*, *συναθροιζω*. Some Hebrew doctors, ſuppoſing the ſame etymon, will have it to have been thus called on account of its *amaſſing* a great deal of wiſdom: others, becauſe the author's aim is to *aſſemble* and *call* together all ſuch as are willing to enjoin their ſafety, and avoid the dangers of the world, which is the opinion of Gejerus. Laſtly, others, with Calvius, deduce it from his *aſſembling* them about him, as a preacher aſſembles his auditors.

There are different ſentiments as to the author of this book; the moſt common is, that it is Solomon's, who is ſuppoſed to have wrote it towards the cloſe of his life, to give tokens of his penitence to poſterity.

Grotius, indeed, takes the work to be poſterior to Solomon, and to have been wrote after his death, by ſix authors unknown, who, to give their book the greater authority, put Solomon's name to it, and repreſented him as repentant. What he chiefly founds his opinion on, is, that we meet with words in this book, which are no where elſe ſeen, but in Daniel, Eſdras, and the Chaldee paraphraſes; but it is certain, all Hebrews, Greeks, and Latins, have always ſpoke of it as a work of Solomon. Indeed there are authors who have attributed all the books of Solomon to Iſaiah; but theſe are only to be underſtood as if that prophet

prophets had collected them. If it be true, that there are Chaldee words in the *Ecclesiastes*, it is easier to suppose Solomon understood that language, than to deny him to be the author of the book.

Calovius allows us, that the true reason why Grotius would not allow Solomon the author of the book of *Ecclesiastes*, is, that it speaks too clearly and precisely for his taste, of the universal judgment, eternal life, and the pains of hell; but these are truths established before Solomon, in the Psalms, the Pentateuch, and Job.

There appears no reason, therefore, for denying this book to Solomon, but several for ascribing it to him. As 1. The title of the book, which asserts its author to be the son of David, and king of Jerusalem. 2. Several passages in the book, which agree to no body but that prince, as chapp. ver. 12. chap. vii. ver. 25. chap. xii. ver. 9. &c. and 2. The constant tradition of the ancient Jews and Christians.

The Talmudists, and other Rabbins note, that it was some time before the book of *Ecclesiastes* was put in the canon. See the *Gemara* on the Pirke Abboth, fol. 1. col. 1. Maffoch Schabbath, cap. ii. fol. 30 col. 2. Aben Ezra on the *Ecclesiastes*, vii. 4. Maimonides, Morch. Nebochim, lib. iii. cap. 28. and Mercerius, Calovius, and Ugolius, on this book.

ECCLESIASTIC, or ECCLESIASTICAL, something belonging to, or set apart for the church, in contradistinction to *civil* or *secular*, which regard the world. See CIVIL, &c. There are *ecclesiastical* things and persons; *ecclesiastical law*, *jurisdiction*, *history*, *ornaments*, *utensils*, *preferments*, &c. *Ecclesiastical* persons are either *regular* or *secular*. See REGULAR and SECULAR. In the empire there are three *ecclesiastical* electors, viz. the archbishops of Mentz, Treves, and Cologne. In France, they have *ecclesiastical peers*, &c. See PEER.

ECCLESIASTIC *chambers*, *communities*, *corporation*, *faith*, *patronage*, *tradition*, *courts*. See the different substantives.

ECCLESIASTICAL *State*, in *Geography*, the pope's dominions in Italy.

These dominions are differently divided by geographers; but the most regular and convenient division is into the following territories: 1. The duchy of Ferrara. 2. That of Bologna. 3. The province of Romagna. 4. The duchy of Urbino. 5. The marquisate of Ancona. 6. The Perugiano. 7. The Orvietano. 8. The duchy of Castro. 9. The Patrimony of St. Peter. 10. Campania di Roma. 11. Sabina. 12. The duchy of Spoleto at Ombria. 13. The county called Citta di Castello. Beside which, the pope is possessed of the following countries out of the papacy, viz. the duchy of Benevento, in the kingdom of Naples; the counties of Avignon and Venaisin, in the southern parts of France. He has, besides, a considerable number of fiefs in Italy, which hold of the papal see; the principal of which are, the kingdom of Naples, and the Rates of Parma and Piacentia.

The POPE may be considered, in two respects, as the spiritual head and monarch of the Roman church, and as a considerable temporal prince in Italy. In the first character, his subjects may be divided into two classes, viz. clergy and laity; the former may not unfitly be compared to a spiritual standing army, whose business is to maintain his rights and conquests; and the rest, the laity, as his tributary subjects, who are obliged to maintain those forces at their own charge; and if one may judge of the greatness of their number, by what pope Paul IV. used to boast, that he had 28800 parishes under his jurisdiction (all of whom have at least one or more priests,) and 4400 monasteries, it will appear no inconsiderable army. But their number has been much lessened since the Reformation.

In the second view, the pope may be considered as a potent prince in Italy, whose sovereignty is chiefly supported by the jealousy between Spain, France, and the Empire; though in most other respects it is not to be compared with that of other princes of Europe. What his revenues are, may be hard to determine, though they must be allowed to be very considerable, and that he is able to maintain a great military force. But this court maintains itself by quite different means from those of temporal princes; and his holiness maintains but very few land forces, though the account at Rome is said to contain arms sufficient, kept in good order and repair, to equip 30000 men, horse and foot. His sea forces consist of 20 gallies, which are commonly stationed at Civita Vecchia.

ECCLESIASTICO *primo*, *secondo*, *terzo*. See PRIMO.

ECCLESIASTICUS, an apocryphal book, composed by Jesus the son of Sirach, and admitted by the Romish church into the canon of the Old Testament.

It is frequently cited by the abbreviation, *Eccles.* to distinguish it from the *Ecclesiastes*, which is cited by *Eccle.*

Isidore, lib. vi. Etym. cap. ii. and among the moderns, Genebrard and Drusius, deny the author of *Ecclesiasticus* to be Jesus the son of Sirach, grandson of the high-priest Jesus, who returned from Babylon with Zorobabel. Genebrard alleges, that Jesus the son of Sirach was of the race of Jesus son of Josedec; but this does not appear.

St. Jerom assures us, in his preface to the books of Solomon, that he had seen this book in Hebrew; and that the Hebrews intitled it *Parables* from which the Jesuit Mariana concludes, that the high-priest Jesus wrote this book in Hebrew, as it appears likewise from the prologue to the book itself; and that his grandson translated it into Greek, which likewise appears from the prologue; that he made this translation in Egypt, where the author lived in his thirty-eighth year; that it was done under the reign of Ptolemy Euergetes, successor of Ptolemy Philadelphus, who began to reign in the year of Rome 512, 240 years before Christ; that the grandfather had entitled it *Parables*, which the grandson changed into *Ecclesiasticus*: lastly, that the book, however, is attributed to the translator because he changed, and added many things to the original.

Fa. Calmet takes the book of *Ecclesiasticus* to have been composed under the pontificate of Onias III. son of Simon, and the reign of Antiochus Epiphanes, king of Syria. He adds, that neither the author of the Latin translation, nor the time when it was made, is known; but being quoted regularly by all the ancient fathers, there is no doubt of its being very ancient. He takes it to have been done by the translator of the Book of Wisdom.

ECCLISIS, from ἐκκλίνω, *I decline*, a word used by Hippocrates, and from him by many other of the old physicians, for a recession of a bone from its proper situation, that is, a luxation.

ECCOPÆUS, from ἐκκόπτω, *I cut*, the name of an instrument, described by some of the ancient writers in *Medicine*, and used for the same purposes for which the modern surgeons employ a lenticular or raspatory. The ancient instrument was a sort of knife, with which they cut down morbid eminences of bones, or took out bones, in case of a fractured scull.

ECCOPE, ἔκκοπη, in *Chirurgery*, the same with excision or amputation.

The word is formed from the Greek, ἐκκόπτω, *excindere*, *to cut off*.

ECCOPE is likewise used for a kind of fracture, or solution of continuity, of the scull, by a simple incision.

ECCOPROTICS, ἐκκοπρωτικὰ, in *Medicine*, laxative, or loosening remedies, which purge gently, by softening the humours and excrements, and fitting them for expulsion.

The word is composed of the Greek particle ἐκ, and κόπρος, *excrement*.

ECCRIMOCRITICA, from ἔκκρισις, *excretion*, and κριτικὸς, in *Medicine*, signs to judge of a distemper, from particular excretions.

ECCRINOLOGICA, from ἔκκρισις and λόγος, a term used, by some writers, for that part of medicine which relates to the doctrine of excretions, or the discharge of any of the excrements out of the body.

ECCRISIS, an excretion of any excrementitious or morbid matter from any of the natural emunctories, as it happens in a perfect crisis. The matter thus excreted is also sometimes called by this name.

ECDICI, Ἔκδικοι, among the *Ancients*, patrons of cities, who defended their rights, and took care of the public money. Their office resembled that of the modern SYNDICS.

ECDORA, from ἐκδύω, *I excoriate*, a word used, by the ancient physicians, to express any kind of excoriation, but in a more particular manner that of the urethra.

ECDORIA, a term used, by the ancient writers in *Medicine*, for such caustic or escharotic medicines, as have a power of taking off the skin.

ECDYSIA, Ἔκδυσια, in *Antiquity*, a festival observed by the Phœnicians in honour of Latona.

ECHAPE', in the *Manege*, is used to denote a horse, got between a stallion and a mare of a different breed and country.

ECHAPER, in the *Manege*, is used in the French academies for giving the horse head, or putting him on full speed. Hence they say, *laisser echapper de la main*.

ECHARPE. See BATTERY *en echarpe*.

ECHAUGUETTE, in the French *Military Art*, an elevated and covered place for a centinel. Richelet explains it by the Latin *specula*, *excubiæ*. See GUERITE.

Some distinguish the *echauguette* from the guerite, giving the former name to centry-boxes made of wood, and square; and the latter name to those made of stone, and round.

ECHENEIS

ECHENEIS, in *Ichthyology*. The ancients have used this as the name of the petromyzon, of some kinds; and Appian, in particular, plainly means by it our common lamprey. See REMORA.

ECHEVIN. See ESCHEVIN.

ECHIDNA, in *Natural History*, a name given, by some authors, "to the several kinds of ophites, or serpent-stone, from *ἐχιδνα*, a *viper*, or *serpent*."

ECHINATE *seeds*, are such as are prickly and rough, like the coat of a chestnut; or, as some say, like the skin of a hedge-hog.

ECHINI *fossiles*. It is a very remarkable observation of Agostino Scilla, that all those fossil *echini* which he had found in the Messinese and Calabrian hills, and about Malta, were, when bruised, as was frequently the case, always bruited by a perpendicular pressure. See ECHINITES.

ECHINI *spatagi*. It is observed, that the fossile *echini spatagi* are very frequent in the island of Malta, and people who are for having all fossil shells to be real terrestrial bodies, produced of seeds in the earth, and never to have been parts of real animals, object to these having ever been such, their being found so plentifully in this fossil state, and so rarely in the native or recent one. This is no objection of weight; because the cornua ammonis give a much stronger, which are a more common fossil, and have never been found recent at all. This is no argument of weight, however, since it is easy to conceive, that the sea, at the time of the universal deluge, might throw up shells from its deep bottom, which we never can get at in fishing or otherwise. And Scilla has proved the absurdity of the objection, in regard to the *echini spatagi*, and shewn that those people who raised it, have been led into it by their ignorance. For he has affirmed, that they may be picked up by hundreds at a time in the port of Messina, and that himself once took up more than a hundred recent ones in an hour.

The shells of this species, found fossil in the island of Malta, are very frequently full of the marle, of which the upper stratum of that island consists; and some of them are cracked, and have been depressed a little inwards. This is an evident proof that they once were real shells, having, in this case, given way, as far as the included marle would let them, on the pressure of some external force. See *Tab.* III. *of Shells*, N° 24.

ECHINITES, or ECHINITÆ, in *Natural History*, the name given by authors to the fossil shells of the several species of *echini marini*, and to the stones formed in them. Of these there is almost an endless variety in the fossil world. Many of those which we daily find in our chalk-pits are the same with those now known to us in their recent state, of living in the sea; but we have numbers of others, of which our imperfect knowledge of the animal world gives us no certain account, in their recent state.

The shells of some of these are found scarce at all altered from their original condition. In many others we have plated spar filling the places of the shells, and retaining every lineament of them. But their most frequent appearance is in the form of masses of hard flint, or other stone, which have been cast and formed in them, having been received, while in a fluid state, into the hollow of the shell, and therefore retaining all the lineaments of the inner surface. And, not unfrequently, these also are coated over with a sparry or stony matter, supplying the place of the shell they were formed in: and having been made, by the insensible deposition of hard matter, in the place of the particles of the shell insensibly wasting away; these retain all the lineaments of the outer part of the shell, as the formed flint does of the inner one. Sometimes pure crystal is found in the place of flint in these, and often crystal, but lightly debased by earth; and these make very elegant specimens.

The various genera of fossil echini, or *echinitæ*, are usually known among authors by the names of *spatagi*, *cordati*, *galeati*, *pileati*, *discoides*, *ovarii*, *pentagylloides*.

What is generally understood by the word *echinites*, is a sort of arched shell, or stones formed in them, covered with divers eminences and cavities, some of which are disposed into beautiful lines, diverging from the summit; and always having two apertures, the one for the mouth, the other for the anus of the animal. Of these,

The *echini cordati* are such as have a remarkable furrow on one side, or end, which is usually broader than any other part of the body, and by means of this furrow, represents, in some degree, the figure of a heart on cards.

The *galeati* are such as have the basis somewhat oblong, and the apertures, one in the very margin, and the other near the margin, on the opposite side. The *pileati* and *discoides*, are subdistinctions of this kind.

The *pileati* are higher, and approach to a conic figure.

The *discoides* are flatter, and more compressed.

The *ovarii* have only one aperture at the base, and have large and unequal tubercles and papillæ.

The *pentagylloides* have rows of short lines, which are so disposed as to represent a cinquefoil leaf.

The *spatagi* is a very comprehensive term, taking in most of the others as subdistinctions. It comprehends all that have two apertures in the base, and that are covered with small tubercles. See *Tab.* III. *of Fossils, Class* 9.

ECHINODERMA, in *Natural History*, the name of the sea animal more commonly known by the name of the *echinus marinus*, or sea hedge-hog. These are fish living in an arched shell, of various figures, according to the various species; and always, besides a vast number of smaller protuberances and cavities, having two remarkable apertures, the one serving for the mouth, the other for the anus of the animal; which are variously placed in the different genera and species.

There are yet wanting, in natural history, the proper characters and distinctions of cruftaceous and testaceous fishes, and, till these are fixed, there is no saying whether these creatures belong to the testaceous or cruftaceous tribe.

Many affirm that the spines of the echini serve them in the place of legs; but there are many also who deny this; and some affirm, that they have, in the living fish, found legs in another part, affixed not to the shell, but to the body of the animal. Klein, Echinod. p. 4. See CENTRONIA.

As to its medical virtues, it is friendly and beneficial to the stomach and belly; and provokes urine. The crude shell toasted is a good ingredient in medicines for abstergingthe psora; and the ashes of it when burnt, cleanse foul ulcers, and repress proud flesh.

ECHINOMETRA, a name given by some to the several depressed species of the *echinodermata*. See *Tab. of Testaceous Animals*, N° 15, 16, 17, and ECHINODERMA.

ECHINOPHORA, in *Botany*. See *Prickly* PARSNIP.

ECHINOPHORA, in *Ichthyology*, a name given by Rondeletius to a species of sea-snail, of the round-mouthed kind, or class of the cochlem lunares.

He calls it *echinophora*, because it is all over beset with tubercles; but this is a very ill chosen name, as it confounds it with the echini or sea-eggs; he had much better have called it cochlea tuberculosa. See LUNARIS *Cochlea*.

ECHINOPHTHALMIA, in the works of the ancient writers on *Medicine*, the name of a disease, which was an inflammation on that part of the eye-lids, which is beset with hairs, or on which the eye-lashes grow.

ECHINOPS, in *Botany*. See *Globe* THISTLE.

ECHINUS, in *Architecture*, a member or ornament, near the bottom of the ionic, Corinthian, and Composite capitals; which from its circular form or contour, is called by the French, *quart de rond*, and by the English, *quarter round*, or *boultin*; and from its being usually carved, or cut with figures of eggs, &c. it is called also by the Latins, *ovum*, by the Italians, *ovolo*, the French, *oeuf*; and the English, *egg* and *anchors*. See *Tab. Archit. fig.* 5. Lastly, the eggs being encompassed with a cover, and thus bearing some resemblance to a chestnut cut open; the Greeks have called it *κεγχρος echinus*, a word which denotes the prickly cover of a chestnut.

ECHINUS, is also used by some botanists for the prickly head, or top of any plant; thus called from its likeness to a hedge-hog, or the cover of a chestnut.

ECHINUS, the hedge-hog, and ECHINUS *marinus*, the sea-urchin. See HEDGE-HOG, ECHINODERMA, and CENTRONIA.

ECHIQUETE. in *Heraldry*. See CHECKY.

ECHITES, in *Botany*, a genus of the *pentandria monogynia* class. The characters of this genus are, that it is twisted, that it has two long straight leaves, a downy seed, and a funnel-shaped flower. There are eleven species.

ECHIUM, in *Botany*. See VIPER'S *Bugloss*.

ECHO, or ECCHO, a sound reflexed, or reverberated from a solid, concave body, and so repeated to the ear. See SOUND, and REFLEXION.

The word is formed of the Greek *ηχος, sound*, of the verb *ηχω, sono, I sound*.

The Peripatetics, who took sound for species, or image of the sonorous body, impressed on the adjoining air, account for *echo* from a reflexion of that species, occasioned by its meeting some obstacle in the way. But the moderns, who know sound to consist in a certain tremor, or vibration in the sonorous body communicated to the contiguous air, and by that means to the ear, give a more consistent account of *echo*.

For a tremulous body, striking on another solid body, it is evident, may be repelled without destroying or diminishing its tremor; and consequently a sound may be redoubled by the reflexion of the tremulous body, or air.

But a simple reflection of the sonorous air is not enough to solve the *echo*: for then every plain surface of a solid hard body, as being fit to reflect a voice or *sound*, would redouble it; which we find does not hold.

To produce an *echo*, therefore, it ſhould ſeem that a kind of concameration or vaulting were neceſſary, in order to collect, and by collecting, to heighten and increaſe, and afterwards reflect the ſound; as we find is the caſe in reflecting the rays of light, where a concave mirror is uſed. In reality, as often as a ſound ſtrikes perpendicularly on a wall, behind which is any thing of a vault, or arch, or even another parallel wall; ſo oft will it be reverberated in the ſame line, or other adjacent ones.

For an *echo* to be heard, therefore, it is neceſſary the ear be in the *line* of reflection; for the perſon who made the ſound to hear its *echo*, it is neceſſary he be in a perpendicular to the place which reflects it; and for a manifold or tautological *echo*, it is neceſſary there be a number of walls and walls, rocks and cavities, either placed behind each other, or fronting each other.

Thoſe murmurs in the air, that are occaſioned by the diſcharge of great guns, &c. are a kind of indefinite *echoes*, and proceed from the vaporous particles ſuſpended in the atmoſphere, which reſiſt the undulations of ſound, and reverberate them to the ear.

A ſingle arch, or concavity, &c. can ſcarce ever ſtop and reflect all the ſound; but if there be a convenient diſpoſition behind it, part of the ſound, propagated thither being collected and reflected, as before, will preſent another *echo*; or if there be another concavity, oppoſed at a due diſtance to the former, the ſound reflected from the one upon the other, will be toſſed back again by this latter, &c.

Many of the phenomena of *echoes* are well conſidered by the biſhop of Leighlin and Ferns, Phil. Tranſ. abr. vol. i. p. 508, &c. who remarks, that any ſound, falling either directly, or obliquely, on any denſe body, of a ſmooth, whether plain or arched, ſuperficies, is reflected, or, in other words, it *echoes* more or leſs. The ſurface, ſays he, muſt be ſmooth, otherwiſe the air, by reverberation, will be put out of its regular motion, and the ſound thereby broke and extinguiſhed. He adds, that it *echoes* more or leſs, to ſhew that when all things are, as before deſcribed, there is ſtill an *echoing*, though it be not always heard; either becauſe the direct ſound is too weak to beat quite back again to him that made it, or that it does return to him, but ſo weak, that it cannot be diſcerned: or that he ſtands in a wrong place to receive the reflected ſound, which paſſes over his head, under his feet, or on one ſide of him, and which therefore may be heard by a man ſtanding in the place where the reflected ſound does come, provided no interpoſed body intercepts it; but not by him that originally made it. There can be no *echo*, unleſs the direct and reflex ſounds follow one another, at a ſufficient diſtance of time, or, in other words, unleſs the difference between the ray proceeding directly to the ear from the ſounding body, and the ſum of the incident and reflex phonic rays be ſufficiently great; for if the reflex ſound arrives at the ear before the impreſſion of the direct ſound ceaſes, the ſound will not be doubled, but only rendered more intenſe. Now if we allow, that no more than nine or ten ſyllables can be pronounced in a ſecond, in order to preſerve the ſounds articulate and diſtinct, there ſhould be about the ninth part of a ſecond between the times of their appulſe to the ear; or, as ſound moves about 1142 feet in a ſecond, the above mentioned difference ſhould be $\frac{1142}{9} = 127$ feet; and therefore every ſyllable will be reflected to the ear at the diſtance of about ſeventy feet from the reflecting body; and as in the ordinary way of ſpeaking three or four ſyllables are uttered in a ſecond, the ſpeaker, in order to have the *echo* returned as ſoon as they are expreſſed, ſhould ſtand about five hundred feet from the reflecting body; and ſo in proportion for any other number of ſyllables. Merſennus allows for a monoſyllable the diſtance of 69 feet; Morton 90 feet; for a diſſyllable 105 feet, a triſyllable 160 feet; a tetraſyllable 182 feet, and a pentaſyllable 204 feet. Nat. Hiſt. Northampton. chap. v. p. 358.

It is plain from the above account, that *echoes* may be applied for meaſuring inacceſſible diſtances. Thus, Dr. Derham, ſtanding upon the banks of the Thames, oppoſite to Woolwich, obſerved that the *echo* of a ſingle ſound was reflected back from the houſes in three ſeconds; conſequently, the ſum of the direct and reflex rays muſt have been $1142 \times 3 = 3426$ feet, and the half of it, or 1713 feet, the breadth of the river in that place.

Echoes may be produced with different circumſtances; for,

1. A *plane* obſtacle reflects the ſound back in its due tone and loudneſs; allowance being made for the proportionable decreaſe of the ſound, according to its diſtance.

2. A *convex* obſtacle reflects the ſound ſomewhat ſmaller, and ſomewhat quicker, though weaker, than it otherwiſe would be.

3. A *concave* obſtacle *echoes* back the ſound, bigger, ſlower, and alſo inverted; but never according to the order of words. Nor does it ſeem poſſible to contrive any ſingle *echo*, that ſhall invert the ſound, and repeat backwards; becauſe, in ſuch a caſe, the word laſt ſpoken, that is, which laſt occurs to the obſtacle, muſt be repelled firſt, which cannot be. For where in the mean time ſhould the firſt words hang, and be concealed; or how, after ſuch a pauſe, ſhould they be revived, and animated again into motion?

From the determinate concavity, or archedneſs of the reflecting bodies, it may happen that ſome of them ſhall only *echo* back one determinate note, and that only from one place.

4. The *echoing* body being removed farther off, it reflects more of the ſound than when nearer; which is the reaſon why ſome *echoes* repeat but one ſyllable, ſome one word, and ſome many. Of theſe ſome are tonical, which only return a voice when modulated into ſome particular muſical tone; and others polyſyllabical.

That fine *echo* in Woodſtock park, Dr. Plott aſſures us, in the day-time, will return very diſtinctly ſeventeen ſyllables, and in the night twenty. See Nat. Hiſt. Oxford. chap. i. p. 7.

5. *Echoing* bodies may be ſo contrived, and placed, as that reflecting the ſound from one to the other, either directly and mutually, or obliquely and by ſucceſſion, out of one ſound, ſhall a *multiple echo*, or many *echoes*, ariſe.

At Roſneath, near Glaſgow, in Scotland, there is an *echo* that repeats a tune played with a trumpet three times completely and diſtinctly. See Birch's Hiſt. of the Royal Society, vol. i. p. 137.

At the ſepulchre of Metella, wife of Craſſus, there was an *echo*, which repeated whatu man ſaid five times. Authors mention a tower at Cyzicus, where the *echo* repeated ſeven times. There is an *echo* at Bruſſels, which anſwers fifteen times.

One of the fineſt *echoes* we read of is that mentioned by Barthius, in his notes on Statius's Thebais, lib. vi. ver. 30. which repeated the words a man uttered ſeventeen times: this was on the banks of the Naha, between Coblentz and Bingen. Barthius aſſures us, he had proved what he writes; and had counted ſeventeen repetitions. And whereas, in common *echoes*, the repetition is not heard till ſome time after hearing the word ſpoke, or the notes ſung; in this the perſon who ſpeaks, or ſings, is ſcarce heard at all; but the repetition very clearly, and always in ſurpriſing varieties; the *echo* ſeeming ſometimes to approach nearer, and ſometimes to be farther off. Sometimes the voice is heard very diſtinctly, and ſometimes ſcarce at all. One perſon hears only one voice, and another ſeveral; one hears the *echo* on the right, and the other on the left, &c.

Addiſon, and other travellers into Italy, mention an *echo* in that country, at Simonetta palace, near Milan, ſtill more extraordinary, which will return the ſound of a piſtol fifty-ſix times, even though the air be very foggy. The *echo* is heard behind the houſe, which has two wings; the piſtol is diſcharged from a window in one of theſe wings, the ſound is returned from a dead wall in the other wing, and heard from a window in the back front. See Addiſ. Trav. edit. 1718. p. 32. Miſſon. Voyag. d'Ital. tom. ii. p. 196. edit. 1691. Phil. Tranſ. N° 480. p. 220.

Add, that a *multiple echo* may be made, by ſo placing the *echoing* bodies, at unequal diſtances, as that they may reflect all one way, and not one on the other; by which means, a manifold ſucceſſive ſound will be heard; one clap of the hands like many; one *ha* like a laughter; one ſingle word like many of the ſame tone and accent; and ſo one muſical inſtrument like many of the ſame kinds, imitating each other.

Laſtly, *echoing* bodies may be ſo ordered, that from any one ſound given, they ſhall produce many *echoes* different both as to tone and intenſion. By which means a muſical room may be ſo contrived, that not only one inſtrument playing therein ſhall ſeem many of the ſame ſort and ſize, but even a conſort of different ones: this may be contrived by placing certain *echoing* bodies ſo as that any note played, ſhall be returned by them in 3ds, 5ths, and 8ths.

ECHO is alſo uſed for the place where the repetition of the ſound is produced, or heard. This is either natural or artificial.

In *echoes*, the place where the ſpeaker ſtands, is called the *centrum phonicum*; and the object, or place, that returns the voice, the *centrum phonicum oppoſitum*.

ECHO, in *Architecture*, is applied to certain vaults, and arches, moſt commonly of elliptical, or parabolical figures; uſed to redouble ſounds, and produce *artificial echoes*.

The

The method of making an *artificial echo* is taught by the Jesuit Biancani, in his Echometria, at the end of his book on the sphere.

Vitruvius tells us, that in divers parts of Greece and Italy there were brazen vessels, artfully ranged under the seats of the theatres, to render the sound of the actors voices more clear, and make a kind of *echo*; by which means, of the prodigious multitude of persons present at those spectacles, every body might hear with ease and pleasure.

ECHO, in *Music*, pieces composed in imitation of *echoes*.

Sometimes also the word *echo* stands for *piano*, intimating that the instrument, or voice, is to play or sing after a soft and sweet manner. Organs and harpsichords have what they call an *echo* stop.

ECHO, in *Poetry*, denotes a kind of composition, wherein the last words, or syllables, of each verse, contain some meaning, which being repeated apart, answers to some question, or other matter, contained in the verse.

Such is that famous *echo* of Erasmus, *Decem annos consumpsit in legendo Cicerone—one*, i. e. *ove*, *ejine*.

The first *echo*, in verse, according to Pasquier, is that in the Sylvæ of Johannes Secundus: but Pasquier is mistaken; for the ancient Greek and Latin poets have wrote *echoes*. This, Martial intimates plainly enough; when, laughing at such sorts of baubles, he says, there is nothing like them among his poems. *Nugarum Græcula quod recantat echo*: by which, on the one side, he shews there were Latin poets, in his time, who made *echoes*; and, on the other, that the invention came from the Greeks.

Aristophanes, in his comedy entitled Θεσμοφοριαζουσαι, introduces Euripides in the person of *Echo*; and Callimachus, in the epigram, Ἔφαμεν το σωμα το κυκλαδιον, seems to have intended a kind of *echo*.

There is a humorous specimen of this kind of poetry in Hudibras.

ECHOMETER, in *Music*, a kind of scale, or rule, with several lines divided thereon, serving to measure the duration, or length, of sounds, and to find their intervals and ratios.

The word is formed of the Greek ηχος *sound*, and μετρον, *measure*.

ECHOS, ηχος, a *sound*, in *Physic*. In Hippocrates this frequently imports what the Latins call *tinnitus aurium*, and the English a ringing of the ears; a symptom very frequent in acute distempers.

ECHPHYAS, from εκ and φυω, *I produce*, an excrescence, or appendix, a word used by many of the ancient writers in medicine. The appendicula vermiformis is thus called by many authors.

ECHTHELYNSIS, from εκθηλυνω, of θηλυς, *feminine*, *I render effeminate*, a term used by the ancient physicians for a laxness, or flabby softness, of the flesh of the legs, or any other part of the body. Some have also used the word to express a fault in bandages, when too loose.

ECLAMPSIS, from λαμπω, *I shine*, a word used by Hippocrates in describing the epilepsy, and, by most people, supposed, by a forced explanation, to mean the change which children undergo at the age of puberty, a time of great consequence in this disease, at which nature shines forth in new lustre, by the increase both of strength and understanding. But the more natural and obvious sense of the word seems to be the expressing of those resplendent flashings and sparklings of light which strike the eyes of persons subject to this distemper, and which are called by Cœlius Aurelianus *scintillarum micæ*, and *circuli ignei*. And the same author, in describing one of his epileptic cases, particularly mentions the flashings of lightning, as it were, which were frequent before his eyes. It is not to be omitted that Hippocrates and Galen have both also used this word in another sense, to express the highest degree of a fever, just before and at the crisis, when it is in its utmost degree of heat, and exerts itself with its utmost violence.

ECLECTIC, Eclectici, a name given to some ancient philosophers, who, without attaching themselves to any particular sect, took what they judged good, and solid, from each.

Hence their denomination; which, in the original Greek, signifies, *that may be chosen*, or *that chooses*; of the verb εκλεγω, *I choose*.

Laertius notes, that they were also, for the same reason, denominated *analogetici*; but that they call themselves *philalethes* i. e. lovers of truth.

The chief, or founder, of the *eclectici*, was one Potamon, of Alexandria, who lived under Augustus and Tiberius; and who, weary of doubting of all things with the Sceptics and Pyrrhonians, formed the *eclectic* sect; which Vossius calls the *eclective*.

Towards the close of the second century a sect arose in the Christian church under the denomination of *Eclectics*, or modern *Platonics*. They professed to make truth the only object of their enquiry, and to be ready to adopt, from all the different systems and sects, such tenets as they thought agreeable to it. However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who at this time laid the foundation of that sect, afterwards distinguished by the name of the new *Platonics*, in the Alexandrian school. This philosopher was born of Christian parents, and educated in the Christian faith, and probably never deserted the outward profession of this religion; though Porphyry maintains, in opposition to the testimony of Eusebius, that in maturer life he became a pagan; and Fabricius, who is followed by Dr. Lardner, alledges that there were two persons of the same name, the one a heathen philosopher, and the other a Christian writer. Those who are desirous of acquainting themselves with the grounds of these opposite opinions, may consult Fabricius's Bibl. Græc. lib. iv. cap. 26. p. 559. Lardner's Collection of Jewish, and Heathen Testimonies, vol. iii. p. 195, &c. and Mosheim, De Rebus Christianorum ante Const. Mag. p. 281, &c.

It was evidently the design of Ammonius to reconcile and unite all sects, philosophical and religious, and to inculcate a doctrine that should comprehend all, the Christians not excepted, in one common profession. For this purpose he maintained, that the great principles of all philosophical and religious truth were to be found, equally, in all sects; that they differed from each other, only in their method of expressing them, and in some opinions of little or no importance; and that, by a proper interpretation of their respective sentiments, they might easily be united into one body. Accordingly, all the gentile religions, and even the Christian, were to be illustrated and explained by the principles of this universal philosophy; and the fables of the priests were to be removed from paganism, and the comments and interpretations of the disciples of Jesus from Christianity. In conformity to this plan he insisted, that all the religious systems of all nations should be restored to their original purity, and reduced to their primitive standard, viz. the ancient philosophy of the East, preserved uncorrupted by Plato; and he affirmed that this project was agreeable to the intentions of Jesus Christ, whose sole view, in descending upon earth, was to set bounds to the reigning superstition, to remove the errors that had blended themselves with the religions of all nations, but not to abolish the ancient theology from which they were derived. He therefore adopted the doctrines which were received in Egypt concerning the universe, and the Deity, considered as constituting one great *whole*, concerning the eternity of the world, the nature of souls, the empire of Providence, and the government of the world by dæmons. He also established a system of moral discipline, which allowed the people in general to live according to the laws of their country, and the dictates of nature, but required the wise to exalt their minds by contemplation, and to mortify the body, so that they might be capable of enjoying the presence and assistance of the dæmons, and of ascending after death to the presence of the Supreme Parent. In order to reconcile the popular religions, and particularly the Christian, with this new system, he made the whole history of the heathen gods an allegory, maintaining that they were only celestial ministers, intitled to an inferior kind of worship; and he acknowledged that Jesus Christ was an excellent man, and the friend of God, but alledged that it was not his design entirely to abolish the worship of dæmons, and that his only intention was to purify the ancient religion. This system, so plausible in its first rise, but so comprehensive and complying in its progress, has been the source of innumerable errors and corruptions in the Christian church. At its first establishment it is said to have had the approbation of Athenagoras, Pantænus, and Clemens the Alexandrian, and of all who had the care of the public school belonging to the Christians at Alexandria. It was afterwards adopted by Longinus, the celebrated author of the Treatise on the Sublime, Plotinus, Herennius, Origen, Porphyry, Iamblichus the disciple of Porphyry, Sopater, Edesius, Eustathius, Maximus of Ephesus, Priscus, Chrysanthius the master of Julian, Julian the Apostate, Hierocles, Proclus, and many others, both Pagans and Christians. Mosheim's Eccl. Hist. vol. i. p. 136, &c. &c. See PLATONISM.

ECLECTICS were also a certain set of physicians among the ancients, of whom Archigenes, under Trajan, was the chief, who selected from the opinions of all the other sects, that which appeared to them best, and most rational;

To produce an *echo*, therefore, it ſhould ſeem that a kind of concameration or vaulting were neceſſary, in order to collect, and by collecting, to heighten and increaſe, and afterwards reflect the ſound; as we find is the caſe in reflecting the rays of light, where a concave mirror is uſed. In reality, as often as a ſound ſtrikes perpendicularly on a wall, behind which is any thing of a vault, or arch, or even another parallel wall; ſo oft will it be reverberated in the ſame line, or other adjacent ones.

For an *echo* to be heard, therefore, it is neceſſary the ear be in the line of reflection; for the perſon who made the ſound to hear its *echo*, it is neceſſary he be in a perpendicular to the place which reflects it; and for a manifold or tautological *echo*, it is neceſſary there be a number of walls and vaults, rocks and cavities, either placed behind each other, or fronting each other.

Thoſe murmurs in the air, that are occaſioned by the diſcharge of great guns, &c. are a kind of indefinite *echoes*, and proceed from the vaporous particles ſuſpended in the atmoſphere, which reſiſt the undulations of ſound, and reverberate them to the ear.

A ſingle arch, or concavity, &c. can ſcarce ever ſtop and reflect all the ſound; but if there be a convenient diſpoſition behind it, part of the ſound, propagated thither being collected and reflected, as before, will preſent another *echo*; or if there be another concavity, oppoſed at a due diſtance to the former, the ſound reflected from the one upon the other, will be toſſed back again by this latter, &c.

Many of the phenomena of *echoes* are well conſidered by the biſhop of Leighlin and Ferns, Phil. Tranſ. abr. vol. i. p. 508, &c. who remarks, that any ſound, falling either directly, or obliquely, on any denſe body, of a ſmooth, whether plain or arched, ſuperficies, is reflected, or, in other words, it *echoes* more or leſs. The ſurface, ſays he, muſt be ſmooth, otherwiſe the air, by reverberation, will be put out of its regular motion, and the ſound thereby broke and extinguiſhed. He adds, that it *echoes* more or leſs, to ſhew that when all things are, as before deſcribed, there is ſtill an *echoing*, though it be not always heard; either becauſe the direct ſound is too weak to beat quite back again to him that made it, or that it does return to him, but ſo weak, that it cannot be diſcerned; or that he ſtands in a wrong place to receive the reflected ſound, which paſſes over his head, under his feet, or on one ſide of him, and which therefore may be heard by a man ſtanding in the place where the reflected ſound does come, provided no interpoſed body intercepts it; but not by him that originally made it. There can be no *echo*, unleſs the direct and reflex ſounds follow one another, at a ſufficient diſtance of time, or, in other words, unleſs the difference between the ray proceeding directly to the ear from the ſounding body, and the ſum of the incident and reflex phonic rays be ſufficiently great; for if the reflex ſound arrives at the ear before the impreſſion of the direct ſound ceaſes, the ſound will not be doubled, but only rendered more intenſe. Now if we allow, that no more than nine or ten ſyllables can be pronounced in a ſecond, in order to preſerve the ſounds articulate and diſtinct, there ſhould be about the ninth part of a ſecond between the times of their appulſe to the ear; or, as ſound moves about 1142 feet in a ſecond, the above mentioned difference ſhould be $\frac{1142}{9} = 127$ feet; and therefore every ſyllable will be reflected to the ear at the diſtance of about ſeventy feet from the reflecting body; and as in the ordinary way of ſpeaking three or four ſyllables are uttered in a ſecond, the ſpeaker, in order to have the *echo* returned as ſoon as they are expreſſed, ſhould ſtand about five hundred feet from the reflecting body; and ſo in proportion for any other number of ſyllables. Merſennus allows for a monoſyllable the diſtance of 69 feet; Morton 90 feet; for a diſſyllable 105 feet, a triſyllable 160 feet; a tetraſyllable 282 feet, and a pentaſyllable 204 feet. Nat. Hiſt. Northampton. chap. v. p. 358.

It is plain from the above account, that *echoes* may be applied for meaſuring inacceſſible diſtances. Thus, Dr. Derham, ſtanding upon the banks of the Thames, oppoſite to Woolwich, obſerved that the *echo* of a ſingle ſound was reflected back from the houſes in three ſeconds; conſequently, the ſum of the direct and reflex rays muſt have been $1142 \times 3 = 3426$ feet, and the half of it, or 1713 feet, the breadth of the river in that place.

Echoes may be produced with different circumſtances; for,

1. A *plane* obſtacle reflects the ſound back in its due tone and loudneſs; allowance being made for the proportionable decreaſe of the ſound, according to its diſtance.

2. A *convex* obſtacle reflects the ſound ſomewhat ſmaller, and ſomewhat quicker, though weaker, than it otherwiſe would be.

3. A *concave* obſtacle *echoes* back the ſound, bigger, ſlower, and alſo inverted; but never according to the order of words. Nor does it ſeem poſſible to contrive any ſingle *echo*, that ſhall invert the ſound, and repeat backwards; becauſe, in ſuch a caſe, the word laſt ſpoken, that is, which laſt occurs to the obſtacle, muſt be repelled firſt, which cannot be. For where in the mean time ſhould the firſt words hang, and be concealed; or how, after ſuch a pauſe, ſhould they be revived, and animated again into motion?

From the determinate concavity, or archedneſs of the reflecting bodies, it may happen that ſome of them ſhall only *echo* back one determinate note, and that only from one place.

4. The *echoing* body being removed farther off, it reflects more of the ſound than when nearer; which is the reaſon why ſome *echoes* repeat but one ſyllable, ſome one word, and ſome many. Of theſe ſome are tonical, which only return a voice when modulated into ſome particular muſical tone; and others polyſyllabical.

That fine *echo* in Woodſtock park, Dr. Plott aſſures us, in the day-time, will return very diſtinctly ſeventeen ſyllables, and in the night twenty. See Nat. Hiſt. Oxford. chap. i. p. 7.

5. *Echoing* bodies may be ſo contrived, and placed, as that reflecting the ſound from one to the other, either directly and mutually, or obliquely and by ſucceſſion, out of one ſound, ſhall a *multiple echo*, or many *echoes*, ariſe.

At Roſneath, near Glaſgow, in Scotland, there is an *echo* that repeats a tune played with a trumpet three times completely and diſtinctly. See Sibbald's Hiſt. of the Royal Society, vol. i. p. 137.

At the ſepulchre of Metella, wife of Craſſus, there was an *echo*, which repeated whatſo man ſaid five times. Authors mention a tower at Cyzicus, where the *echo* repeated ſeven times. There is an *echo* at Briſſels, which anſwers fifteen times.

One of the fineſt *echoes* we read of is that mentioned by Barthius, in his notes on Statius's Thebais, lib. vi. ver. 30. which repeated the words a man uttered ſeventeen times: this was on the banks of the Naha, between Coblentz and Bingen. Barthius aſſures us, he had proved what he writes; and had counted ſeventeen repetitions. And whereas, in common *echoes*, the repetition is not heard till ſome time after hearing the word ſpoke, or the notes ſung; in this the perſon who ſpeaks, or ſings, is ſcarce heard at all; but the repetition very clearly, and always in ſurpriſing varieties; the *echo* ſeeming ſometimes to approach nearer, and ſometimes to be farther off. Sometimes the voice is heard very diſtinctly, and ſometimes ſcarce at all. One perſon hears only one voice, and another ſeveral; one hears the *echo* on the right, and the other on the left, &c.

Addiſon, and other travellers into Italy, mention an *echo* in that country, at Simonetta palace, near Milan, ſtill more extraordinary, which will return the ſound of a piſtol fifty-ſix times, even though the air be very foggy. The *echo* is heard behind the houſe, which has two wings; the piſtol is diſcharged from a window in one of theſe wings, the ſound is returned from a dead wall in the other wing, and heard from a window in the back front. See Addiſ. Trav. edit. 1718. p. 32. Miſſon. Voyag. d'Ital. tom. ii. p. 196. edit. 1691. Phil. Tranſ. N° 480. p. 220.

Add, that a *multiple echo* may be made, by ſo placing the *echoing* bodies, at unequal diſtances, as that they may reflect all one way, and not one on the other; by which means, a manifold ſucceſſive ſound will be heard; one clap of the hands like many; one *ha* like a laughter; one ſingle word like many of the ſame tone and accent; and ſo one muſical inſtrument like many of the ſame kinds, imitating each other.

Laſtly, *echoing* bodies may be ſo ordered, that from any one ſound given, they ſhall produce many *echoes* different both as to tone and intenſion. By which means a muſical room may be ſo contrived, that not only one inſtrument playing therein ſhall ſeem many of the ſame ſort and *tune*, but even a conſort of different ones: this may be contrived by placing certain *echoing* bodies ſo as that any note played, ſhall be returned by them in 3ds, 5ths, and 8ths.

ECHO is alſo uſed for the place where the repetition of the ſound is produced, or heard. This is either natural or artificial.

In *echoes*, the place where the ſpeaker ſtands, is called the *centrum phonicum*; and the object, or place, that returns the voice, the *centrum phonicum oppoſitum*.

ECHO, in *Architecture*, is applied to certain vaults, and arches, moſt commonly of elliptical, or parabolical figures; uſed to redouble ſounds, and produce *artificial echoes*.

The

The method of making an *artificial echo* is taught by the Jesuit Bianeani, in his Echometria, at the end of his book on the sphere.

Vitruvius tells us, that in divers parts of Greece and Italy there were brazen vessels, artfully ranged under the seats of the theatres, to render the sound of the actors voices more clear, and make a kind of *echo*; by which means, of the prodigious multitude of persons present at those spectacles, every body might hear with ease and pleasure.

ECHO, in *Music*, pieces composed in imitation of *echoes*.

Sometimes also the word *echo* stands for *piano*, intimating that the instrument, or voice, is to play or sing after a soft and sweet manner. Organs and harpsichords have what they call an *echo* stop.

ECHO, in *Poetry*, denotes a kind of composition, wherein the last words, or syllables, of each verse, contain some meaning, which being repeated apart, answers to some question, or other matter, contained in the verse.

Such is that famous *echo* of Erasmus, *Deiem annos consumpsit in legendo Ciceronе—one*, i. e. *ass*, *esses*.

The first *echo*, in verse, according to Pasquier, is that in the Sylvæ of Johannes Secundus: but Pasquier is mistaken; for the ancient Greek and Latin poets have wrote *echoes*. This, Martial intimates plainly enough; when, laughing at such sorts of baubles, he says, there is nothing like them among his poems. *Nequeunt Graecula quod resonat echo*: by which, on the one side, he shews there were Latin poets, in his time, who made *echoes*; and, on the other, that the invention came from the Greeks.

Aristophanes, in his comedy entitled Θεσμοφοριαζουσαι, introduces Euripides in the person of *Echo*; and Callimachus, in the epigram, Εκαεργη το φωνημα το κυκλικον, seems to have intended a kind of *echo*.

There is a humorous specimen of this kind of poetry in Hudibras.

ECHOMETER, in *Music*, a kind of scale, or rule, with several lines divided thereon, serving to measure the duration, or length, of sounds, and to find their intervals and ratios.

The word is formed of the Greek ηχος, *sound*, and μετρον, *measure*.

ECHOS, Ηχος, a *sound*, in *Physic*. In Hippocrates this frequently imports what the Latins call *tinnitus aurium*, and the English a ringing of the ears; a symptom very frequent in acute distempers.

ECHPHYAS, from εκ and φυω, *I produce*, an excrescence, or appendix, a word used by many of the ancient writers in medicine. The appendicula vermiformis is thus called by many authors.

ECHTHELYNSIS, from εκθηλυνω, of θηλυς, *feminine*, *I render effeminate*, a term used by the ancient physicians for a laxness, or flabby softness, of the flesh of the legs, or any other part of the body. Some have also used the word to express a fault in bandages, when too loose.

ECLAMPSIS, from λαμπω, *I shine*, a word used by Hippocrates in describing the epilepsy, and, by most people, supposed by a forced explanation, to mean the change which children undergo at the age of puberty, a time of great consequence in this disease, at which nature shines forth in new lustre, by the increase both of strength and understanding. But the more natural and obvious sense of the word seems to be the expressing of those resplendent flashings and sparklings of light which strike the eyes of persons subject to this distemper, and which are called by Cælius Aurelianus *scintillarum vices*, and *circuli ignei*. And the same author, in describing one of his epileptic cases, particularly mentions the flashings of lightning, as it were, which were frequent before his eyes. It is not to be omitted that Hippocrates and Galen have both also used this word in another sense, to express the highest degree of a fever, just before and at the crisis, when it is in its utmost degree of heat, and exerts itself with its utmost violence.

ECLECTIC, Eclectici, a name given to some ancient philosophers, who, without attaching themselves to any particular sect, took what they judged good, and solid, from each.

Hence their denomination; which, in the original Greek, signifies, *that may be chosen*, or *that chooses*; of the verb εκλεγω, *I choose*.

Lactius notes, that they were also, for the same reason, denominated *analogetici*; but that they call themselves *philalethes* i. e. lovers of truth.

The chief, or founder, of the *eclectici*, was one Potamon, of Alexandria, who lived under Augustus and Tiberius; and who, weary of doubting of all things with the Sceptics and Pyrrhonians, formed the *eclectic* sect; which Vossius calls the *selective*.

Towards the close of the second century a sect arose in the Christian church under the denomination of *Eclectics*, or modern *Platonics*. They professed to make truth the only object of their enquiry, and to be ready to adopt, from all the different systems and sects, such tenets as they thought agreeable to it. However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who at this time laid the foundation of that sect, afterwards distinguished by the name of the new *Platonics*, in the Alexandrian school. This philosopher was born of Christian parents, and educated in the Christian faith, and probably never deserted the outward profession of this religion; though Porphyry maintains, in opposition to the testimony of Eusebius, that in maturer life he became a pagan; and Fabricius, who is followed by Dr. Lardner, alledges that there were two persons of the same name, the one a heathen philosopher, and the other a Christian writer. Those who are desirous of acquainting themselves with the grounds of these opposite opinions, may consult Fabricius's Bibl. Græc. lib. iv. cap. 26. p. 559. Lardner's Collection of Jewish, and Heathen Testimonies, vol. iii. p. 195, &c. and Mosheim, De Rebus Christianorum ante Const. Mag. p. 281, &c.

It was evidently the design of Ammonius to reconcile and unite all sects, philosophical and religious, and to inculcate a doctrine that should comprehend all, the Christians not excepted, in one common profession. For this purpose he maintained, that the great principles of all philosophical and religious truth were to be found, equally, in all sects; that they differed from each other, only in their method of expressing them, and in some opinions of little or no importance; and that, by a proper interpretation of their respective sentiments, they might easily be united into one body. Accordingly, all the gentile religions, and even the Christian, were to be illustrated and explained by the principles of this universal philosophy; and the fables of the priests were to be removed from paganism, and the comments and interpretations of the disciples of Jesus from Christianity. In conformity to this plan he insisted, that all the religious systems of all nations should be restored to their original purity, and reduced to their primitive standard, viz. the ancient philosophy of the East, preserved uncorrupted by Plato; and he affirmed that this project was agreeable to the intentions of Jesus Christ, whose sole view, in descending upon earth, was to set bounds to the reigning superstition, to remove the errors that had blended themselves with the religions of all nations, but not to abolish the ancient theology from which they were derived. He therefore adopted the doctrines which were received in Egypt concerning the universe, and the Deity, considered as constituting one great *whole*, concerning the eternity of the world, the nature of souls, the empire of Providence, and the government of the world by demons. He also established a system of moral discipline, which allowed the people in general to live according to the laws of their country, and the dictates of nature, but required the wise to exalt their minds by contemplation, and to mortify the body, so that they might be capable of enjoying the presence and assistance of the demons, and of ascending after death to the presence of the Supreme Parent. In order to reconcile the popular religions, and particularly the Christian, with this new system, he made the whole history of the heathen gods an allegory, maintaining that they were only celestial ministers, intitled to an inferior kind of worship; and he acknowledged that Jesus Christ was an excellent man, and the friend of God, but alledged that it was not his design entirely to abolish the worship of demons, and that his only intention was to purify the ancient religion. This system, so plausible in its first rise, but so comprehensive and complying in its progress, has been the source of innumerable errors and corruptions in the Christian church. At its first establishment it is said to have had the approbation of Athenagoras, Pantænus, and Clemens the Alexandrian, and of all who had the care of the public school belonging to the Christians at Alexandria. It was afterwards adopted by Longinus, the celebrated author of the Treatise on the Sublime, Plotinus, Herennius, Origen, Porphyry, Jamblichus the disciple of Porphyry, Sopater, Edesius, Eustathius, Maximus of Ephesus, Prisceus, Chrysanthius the master of Julian, Julian the Apostate, Hierocles, Proclus, and many others, both Pagans and Christians. Mosheim's Eccl. Hist. vol. i. p. 536, &c. &c. See PLATONISM.

ECLECTICS were also a certain set of physicians among the ancients, of whom Archigenes, under Trajan, was the chief, who selected from the opinions of all the other sects, that which appeared to them best, and most rational,

tional; hence they were called *eclectici*, and their prescriptions *medicina eclectica*.

ECLEGMA, or ECLIGMA, ἔκλειγμα, or ECLECTOS, in *Medicine*, a pectoral remedy, of the consistence of a thick syrup; called, also, *lohoch*, *linctus*, and *lambativum*.

The word is Greek; formed of ἐκ, and λείχω, *to lick*; because the patient is to take it by licking it off the end of a liquorice stick dipt therein; in order that, being taken thus by little and little, it may remain the longer in the passage, and moisten the breast the better.

There are *eclegmas* of the syrups of poppy, others of lentils, others of squills, &c. Their intention is to heal or ease the lungs, in coughs, peripneumonies, &c. They are usually compoled of oils, incorporated with syrups.

ECLIPSAREON, in *Astronomy*, is an instrument invented by Mr. Fergoson for exhibiting the time, quantity, duration, and progress of solar eclipses, at all parts of the earth. This machine consists of a terrestrial globe A, (*Tab. II. Astronomy, fig.* 30.) turned, by a winch M, round its axis B, inclining 23½°, and carrying an index round the hour-circle D; a circular plate E, on which the months and days of the year are inserted, and which supports the globe in such a manner, that when the given day of the month is turned to the annual index G, the axis has the same position with the earth's axis at that time; a crooked wire F, which points to the middle of the earth's enlightened disc, and shews to what place of the earth the sun is vertical at any given time; a penumbra, or thin circular plate of brass I, divided into 12 digits, by 12 concentric circles, and so proportioned to the size of the globe, that its shadow, formed by the sun, or a candle placed at a convenient distance, with its rays transmitted through a convex lens, to make them fall parallel on the globe, may cover those parts of the globe, which the shadow and penumbra of the moon cover on the earth; an upright frame HHHH, on the sides of which are scales of the moon's latitude, with two sliders K and K fitted to them, by means of which the centre of the penumbra may be always adjusted to the moon's latitude; a solar horizon C, dividing the enlightened from the darkened hemisphere, and shewing the places where the general eclipse begins and ends with the rising or setting sun; and a handle M, which turns the globe round its axis by wheel work, and moves the penumbra across the frame by threads over the pulleys L, L, L, with a velocity duly proportioned to that of the moon's shadow over the earth, as the earth turns round its axis.

If the moon's latitude at any conjunction exceeds the number of divisions on the scales, there can be no eclipse; if not, the sun will be eclipsed to some parts of the earth; the appearances of which may be represented by the machine, either with the light of the sun, or of a candle. For this purpose, let the indexes of the sliders KK point to the moon's latitude, the plate E be turned till the day of the given new moon comes to G, and the penumbra be moved till its centre comes to the perpendicular thread in the middle of the frame, which thread represents the axis of the ecliptic; then turn the handle till the meridian of London on the globe comes under the point of the wire F, and turn the hour circle D, till XII at noon comes to its index; and turn the handle till the hour-index points to the time of new moon in the circle D, and then screw fast the collar N. Lastly, elevate the machine, till the sun shines through the sight-holes in the small upright plates O, O, on the pedestal; or, place a candle before the machine, at the distance of about four yards, so that the shadow of the intersection of the cross thread in the middle of the frame may fall precisely on that part of the globe to which the wire F points; with a pair of compasses take the distance between the centre of the penumbra, and the intersection of the threads, and set the candle higher or lower, according to that distance; and place a large convex lens between the machine and candle, so that the candle may be in the focus of the lens; and thus the machine is rectified for use.

Let the handle be turned backward, till the penumbra almost touches the side HF of the frame, and then, turning it forward, the following phenomena may be observed. 1. Where the eastern edge of the shadow of the penumbral plate, I, first touches the globe at the solar horizon, those who inhabit the corresponding part of the earth see the eclipse begin on the uppermost edge of the sun, just at the time of its rising. 2. In that place where the penumbra's centre first touches the globe, the inhabitants have the sun rising upon them centrally eclipsed. 3. When the whole penumbra just falls upon the globe, its western edge at the solar horizon touches and leaves the place where the eclipse ends at sun-rise on his lowermost edge. 4. By continued turning, the cross lines in the centre of the penumbra will go over all those places on the globe where the sun is centrally eclipsed. 5. When the eastern edge of the shadow touches any place of the globe, the eclipse begins there; when the vertical line, in the penumbra comes to any place, then is the greatest obscuration at that place; and when the western edge of the penumbra leaves the place, the eclipse ends there, and the times are shewn on the hour-circle; and from the beginning to the end, the shadows of the concentric penumbral circles shew the number of digits eclipsed at all the intermediate times. 6. When the eastern edge of the penumbra leaves the globe at the solar horizon C, the inhabitants see the sun beginning to be eclipsed on his lowermost edge at its setting. 7. Where the penumbra's centre leaves the globe, the inhabitants see the sun centrally eclipsed; and lastly, where the penumbra is wholly departing from the globe, the inhabitants see the eclipse ending on the uppermost part of the sun's edge, at the time of its disappearing in the horizon.

This instrument will likewise serve for exhibiting the times of sun rising and setting, and of morning and evening twilight, as well as the places to which the sun is vertical on any day, by setting the day on the plate E to the index G, turning the handle till the meridian of the place comes under the point of the crooked wire F, and bringing XII on the hour-circle D to the index: then if the globe be turned, till the place touches the eastern edge of the horizon C, the index shews the time of sun-setting; and when the place comes out from below the other edge of C, the index shews the time when evening twilight ends; and morning twilight and sun-rising are shewn in the same manner on the other side of the globe. And the places under the point of the wire F are those to which the sun passes vertically on that day. Ferguson's Astronomy, p. 268, &c. 4to edit. or Phil. Trans. vol. xlviii. p. 520.

ECLIPSE, from ἔκλειψις, of ἐκλείπω, *cefsein*, *I fail*, in *Astronomy*, a privation of the light of one of the luminaries, by the interposition of some opake body, either between it and the eye, or between it and the sun.

The ancients had frightful ideas of *eclipses*, suppoling them prefages of the most direful events. Plutarch assures us, that, at Rome, it was not allowed to talk publickly of any natural causes of *eclipses*. They made a great noise with brazen instruments, and raised loud shouts, during *eclipses* of the moon; as thinking, thereby, to ease her in labour: whence Juvenal, speaking of a talkative woman, says, *Una laboranti parerit fa.curre lunæ*. Others attributed the *eclipse* of the moon to the arts of magicians, who, by their enchantments, plucked her out of heaven, and made her skim over the grass. The natives of Mexico kept fast, during *eclipses*; and particularly their women, who beat and abuse themselves, drawing blood from their arms, &c. They imagine the moon has been wounded by the sun, in some quarrel between them.

The Chinese fancy that *eclipses* are occasioned by great dragons, who are ready to devour the sun and moon, and therefore, when they perceive an *eclipse*, they rattle drums and brass kettles, till the monster, terrified by the noise, leaves his prey. The superstitious nations entertained of *eclipses* were once of considerable advantage to Christopher Columbus, when, in 1493, he was driven on the island of Jamaica, and distressed for want of provisions, was refused relief; but having threatened them with a plague, and foretelling an *eclipse*, as a token of it, which happened according to his prediction, the barbarians were so terrified, that they strove who should be the first in bringing him supplies, throwing them at his feet, and imploring forgiveness. Riccioli's Almag. vol. i. lib. v. cap. 2. § 14. or p. 291.

ECLIPSE, *the duration of an*, is the time between the immersion and emersion.

ECLIPSE, *immersion, or incidence, of an*, is the moment when part of the sun, planet, or moon's disk, first begins to be hidden. See IMMERSION.

ECLIPSE, *emersion, or reimmersion, of an*, is the time when the *eclipsed* luminary begins to re-appear, or emerge out of the shadow.

To determine the duration of *eclipses*, they usually divide the diameter of the luminary *eclipsed* into 12 equal parts, called *digits*, or *digiti eclipsis*.

Eclipses are divided, with respect to the luminary *eclipsed*, into *eclipses of the sun*, or *the moon*, and of the *fixed stars*; and, with respect to the circumstances, into *total*, *partial*, *annular*, &c. *eclipses*.

ECLIPSE *of the moon*, is a deficiency of light in the moon, occasioned by a diametrical oppolition of the earth, between the sun and moon.

The manner of this *eclipse* is exhibited in *Tab. Astronomy*, *fig.* 34. where A represents the earth, and B, or C, the moon.

When

When all the light of the moon is intercepted, i. e. when her whole disk is covered, the *eclipse* is said to be *total*; when only part, *partial*; when the *total eclipse* lasts for some time, it is said to be *totalis cum mora, total with continuance*; when only instantaneous, *totalis sine mora, total without continuance*.

Eclipses of the moon only happen in the time of full moon: because it is only then the earth is between the sun and moon: nor do they happen every full moon, by reason of the obliquity of the moon's way with respect to the sun's; but only in those full moons which happen either in the nodes, or very near them, where the aggregate of the apparent semidiameters of the moon and the earth's shadow is greater than the latitude of the moon, or the distance between their centres.

The most favourable circumstances in the eclipses *of the moon are*, 1. That as the sum of the semidiameters of the moon and earth's shadow is greater than the aggregate of the semidiameters of the sun and moon (that, when least, being 57; and this, when greatest, scarce 35); if it is evident, *lunar eclipses* may happen in a greater latitude of the moon, and at a greater distance from the nodes, and, consequently, are more often observed, in any one part of the earth, than *solar* ones; though, with respect to the whole earth, the latter are more frequent than the former, because the sun's ecliptic limits are greater than the moon's.

2. *Total eclipses*, and those of the longest duration, happen in the very nodes of the ecliptic; because the section of the earth's shadow, then falling on the moon, is considerably greater than her disc. There may likewise be *total eclipses* within a little distance of the nodes; but the farther, the less their duration; farther off still, there are only partial ones, and, at length, none at all; as the latitude and the semidiameter of the moon, together, are either less, equal, or greater than the semidiameter of the shadow.

3. All *lunar eclipses* are universal, i. e. are visible in all parts of the globe which have the moon above their horizon; and are every where of the same magnitude, and begin and end together.

4. In all *lunar eclipses*, the eastern side is what first immerges, and also emerges; so that though, at first, the moon be more westerly than the earth's shadow, yet her proper motion being swifter than the same, she overtakes and outgoes it.

5. The moon, even in the middle of an *eclipse*, has usually a faint appearance of light, resembling tarnished copper; which Gassendus, Riccioloy, Kepler, &c. attribute to the light of the sun, refracted by the earth's atmosphere, and transmitted thither.

Lastly, she grows sensibly paler, and dimmer, before she enters within the earth's shadow; which is attributed to the earth's PENUMBRA.

Astronomy of lunar ECLIPSES, *or the method of calculating their times, places, magnitudes, and other phenomena.* Preliminary 1. To find the length of the earth's shadowy cone. Find the sun's distance from the earth for the given time. See SUN, and DISTANCE. Then, as the sun's diameter is known in semidiameters of the earth, the length of the cone will be found from the *rules* given under SHADOW. Suppose, e. gr. the distance of the sun from the earth to be 95,000000 miles, and the eccentricity of the orbit 1,377060 miles, then will the greatest distance be 96,377060, or 24094 semidiameters of the earth; and the sun's semidiameter to that of the earth as 112 to 1, then will the length of the shadowy cone be 217 diameters of the earth.

Or, in the triangle *a b c* (*Tab.* II. *Astronomy, fig.* 71.) let *a b* represent the semidiameter of the sun, which at his greatest distance from the earth, whose semidiameter is *c d*, appears under the angle *a c b* equal to 15′ 44″; let the sun's parallax, or the angle *c b d*, for the sake of avoiding fractions, be 9″; then will the angle *d c e*, or the semi-angle of the conical shadow, be 15′ 35″; whence in the triangle *d c e*, we shall have, by trigonometry, the tangent of 15′ 35″ to radius as *e d*, or 1 semidiameter of the earth to *c e*: i. e. by Gardiner's Logarithmic Tables, 7,656638 to 10,000, &c.: 0,000, &c.: 2,343618, which is the logarithm of the number 220.6 nearly; and therefore the length of the shadow is thus found to be above 220 semidiameters of the earth. But if the parallax be neglected, and the semi-angle of the cone supposed to be 15′ 50″, the height of the shadow will be only somewhat more than 217 semidiameters of the earth. And if we suppose the moon's shadow to be similar to that of the earth, and the proportion of their semidiameters as 28 to 100, we shall have the height of the moon's shadow in the same circumstances, above 61 semidiameters of the earth.

Hence, as the moon's least distance from the earth is scarce 56 semidiameters, and the greatest not more than 64; the moon, when in opposition to the sun, in or near the nodes, will fall into the earth's shadow, though the sun and moon be in their apogees; and much more, if they be in or near their perigees; because the shadow is then longer, and the moon nearer the base of the cone.

2. To find the apparent semidiameter of the earth's shadow, in the place of the moon's passage, for any given time. Find the sun and moon's distance from the earth, and thence their horizontal parallaxes; add the parallaxes together, and from the sum subtract the apparent semidiameter of the sun; the remainder is the apparent semidiameter of the shadow.

Thus, suppose the moon's horizontal parallax 57′ 18″, the sun's 9″; the sum is 57′ 27″: from which if the sun's apparent semidiameter 16′ 5″ be subtracted, we shall have 41′ 22″ for the semidiameter of the shadow.

Note, M. De la Hire omits the sun's parallax, as of no consideration; but increases the apparent semidiameter of the shadow by a whole minute, for the shadow of the atmosphere; which would give the semidiameter of the shadow, in our instance, 42′ 13″.

3. The moon's latitude, AL, at the time of her opposition, together with the angle at the node B, being given; to find the arch between the centres A I, and the arch I L. (*fig.* 35.) Since in the spherical triangle A I L, rectangular at I, the side A L is given; as also the angle A L I, which is the complement of L A I, or B, to a right angle; the arch between the centres, A I, is found by spherical trigonometry; and since the angle L A I is equal to B, each of them, with I A B, making a right angle; and the moon's latitude A L is given; the arch L I will likewise be found by spherical trigonometry. See SPHERICAL *triangle*.

ECLIPSE *of the moon to determine the bounds of an.* Since there is no *eclipse* possible, but when the aggregate of the semidiameters of the shadow and the moon is greater than the moon's latitude (for, without this, the moon will not come in the shadow) add the apparent semidiameters of the moon in perigee, and of the shadow, supposing the sun in apogee; by which you will have the side M O, *fig.* 36. Then, in the spherical triangle M N O, having given the angle at the node, whose quantity is the moon's greatest latitude in the conjunctions; the right angle M, and the leg M O; find the moon's distance from the node N O; which is the utmost bound, beyond which the *eclipse* cannot reach. After the same manner, adding the apparent semidiameters of the moon in apogee, and of the shadow of the earth when the sun is in perigee, for the sake of having the side L H in the triangle N L H, the distance of the moon, from the ascending node H N, will be found by spherical trigonometry; which is the bound within which the moon will necessarily be *eclipsed*.

Thus, e. gr. the semidiameter of the shadow, when the sun is in apogee, and the moon in perigee, according to Kepler, is 49′ 40″. And the apparent semidiameter of the moon in perigee, 16′ 24″. Consequently M O is 66′, or 1° 6′; and therefore there will be no eclipse at all, if the moon's latitude be greater than 1° 6′. Now, as the same angle N is supposed by Kepler to be 5° 18′,

Log. sin. N	8.9655337
Sin. M O	8.2832433
Whole sine	10.0000000
Log. of sine O N	9.3177096

The number corresponding to which in the tables is 11° 50′ 50″. If, therefore, the moon's distance from either of the nodes be greater than 12°, no *eclipse* will generally happen. And, in like manner, the semidiameter of the shadow in the sun's perigee, and the moon's apogee, is 43′ 30″, and the moon's semidiameter in her apogee 15′. Consequently L H is 58′ 50″. And therefore there will be an *eclipse*, if the moon's latitude doth not exceed 58′ 50″. This, however, admits of some variation; for when the full moon is in her apogee, she will be *eclipsed*, if she be within 12½ degrees of the node; and when she is full in her perigee, she will be *eclipsed*, if she be within 12½ of the node.

To determine the quantity of an eclipse, *or the number of digits* eclipsed.—Add the moon's semidiameter I K (*fig.* 35.) to the semidiameter of the shadow A M; then will A M + I K = A I + I M + I K = A I + M K. From this sum, therefore, subtract the arch between the centres A I, the remainder gives the scruples or parts of the diameter *eclipsed* M K. Say, therefore, as the moon's diameter K H is to the scruples or parts thereof *eclipsed*, M K, so is 12 to the digits *eclipsed*.

To find the scruples of half duration of an eclipse, *or the arch of the lunar orbit, which her centre describes from the beginning of the* eclipse *to the middle thereof.* Add the semidiameters of the shadow A P, and the moon P N together; the

ſum gives AN. From the ſquare of AN ſubtract the ſquare of AI; the remainder is the ſquare of IN. And the ſquare root of this reſidue is the arch IN required.

To find the ſcruples of half duration of total darkneſs in a total eclipſe. Subtract the moon's ſemidiameter SV (*fig.* 37.) from the ſemidiameter of the ſhadow AV; the remainder is AS: in the triangle AIS, which is rectangular at I, therefore, we have the arch AS given by the laſt method; and the arch between the centres AI; where the arch IS is found, as in the laſt problem.

To find the beginning, middle, and end, of a lunar eclipſe. Say, as the moon's horary motion from the ſun is to 3600 horary ſeconds; ſo are the ſeconds of the arch LI (*fig.* 35.) to the horary ſeconds equivalent thereto. Subtract theſe ſcruples or ſeconds, in the firſt and third quadrant of the anomaly, from the time of full moon, and add it to the ſame in the ſecond and fourth; the reſult is the time of the middle of the *eclipſe*. Then ſay, as the moon's horary motion from the ſun is to 3600 ſcruples, or ſeconds, ſo are the ſeconds of half duration IN to the time of half duration; the double of which gives the whole duration. Laſtly, ſubtract the time of half duration from the time of the middle of the *eclipſe*, the remainder will be the beginning of the *eclipſe*. And add the ſame to the ſame, the ſum will be its end.

A lunar *eclipſe*, that is both total and central, laſts 3 hours 57 minutes 6 ſeconds, from the beginning to the end, when the moon is in her apogee; and 3 hours 37 minutes 26 ſeconds, when in perigee: her horary motion being ſloweſt in the former caſe, and quickeſt in the latter.

To calculate an eclipſe *of the moon.* 1. For the given time of the mean full moon, compute the moon's diſtance from the node, to find whether there be an *eclipſe* or not; as taught in the firſt problem.

2. Compute the time of the true full moon, with the ſun and moon's true place reduced to the ecliptic.

3. For the time of the true full moon, compute the moon's true latitude, and the diſtance of each luminary from the earth, with the horizontal parallaxes, and apparent ſemidiameters.

4. For the ſame time, find the ſun and moon's true horary motion.

5. Find the apparent ſemidiameter of the ſhadow. And,

6. The arch between the centres AI, with the arch LI.

7. Compute the ſcruples of half duration IN. And thence,

8. Determine the beginning, middle, and end, of the *eclipſe*.

Laſtly, Find the ſcruples *eclipſed*, and thence the quantity of the *eclipſe*, as taught under the preceding problems.

To draw a type, or figure, of a lunar eclipſe *on a plane.*

1. Let CD (*fig.* 38.) repreſent the ecliptic; and let the centre of the ſhadow be in A; through which draw a right line GQ perpendicular to DC; and ſuppoſe D the eaſt, C the weſt, Q the ſouth, and G the north.

2. From A, with the interval of the aggregate AN, of the ſemidiameter of the ſhadow AP, and of the moon PN, deſcribe a circle DGCQ; and with the interval of the ſemidiameter of the ſhadow AP, draw another concentric circle EF; which will exhibit the ſection of the ſhadow in the paſſage of the moon.

3. Let AL be equal to the latitude of the moon at the beginning of the *eclipſe*; and in L erect a perpendicular LN, meeting the greater circle in N, towards the weſt. Then will the centre of the moon, at the beginning of the *eclipſe*, be in N.

4. After like manner, make AS equal to the latitude of the moon at the end of the *eclipſe*; and in S erect a perpendicular OS, parallel to DC; then will the centre of the moon be in O, at the end of the *eclipſe*.

5. Connect the points O and N by a right line; ON will be the arch of the orbit, which the centre of the moon deſcribes during the *eclipſe*.

6. From O and N, with the interval of the moon's ſemidiameter, deſcribe circles PV and TX, which will exhibit the moon at the beginning and end of the *eclipſe*.

7. Then, from A, letting fall a perpendicular AI to ON; the centre of the moon will be in I, in the middle of the darkneſs.

Wherefore, laſtly, from I, with the interval of the moon's ſemidiameter, deſcribe a circle HK: this will repreſent the moon in the greateſt darkneſs, and at the ſame time the quantity of the *eclipſe*.

ECLIPSE *of the ſun*, is an occultation of the ſun's body, occaſioned by an interpoſition of the moon between the ſun and the earth.

It is diſtinguiſhed, like that of the moon, into *total* and *partial*, &c. to which muſt be added a third ſpecies called *annular*.

Eclipſes of the ſun, ſome authors obſerve, ſhould in propriety be called *eclipſes of the earth*.

As the moon is found to have a parallax of latitude, *eclipſes* of the ſun only happen when the latitude of the moon, viewed from the earth, is leſs than the aggregate of the apparent ſemidiameters of the ſun and moon. *Solar eclipſes*, therefore, happen when the moon is in conjunction with the ſun, in or near the nodes, i. e. at the new moons. Conſequently, the memorable *eclipſe of the ſun*, at our Saviour's paſſion, happening at the time of full moon, when the ſun and moon are in oppoſition, was preternatural. Beſides, the darkneſs in total *eclipſes* of the ſun never laſts above four minutes in one place; whereas the darkneſs of the crucifixion laſted three hours, Matt. xxviii. 15. and overſpread, at leaſt, all the land of Judea.

Though the new moon paſs between the ſun and the earth, yet is not there an *eclipſe* every moon; becauſe the moon's way is not preciſely under the ecliptic, but is placed obliquely thereto; only interſecting it twice in every period. So that *eclipſes* can only be occaſioned in ſuch new moons, as happen in theſe interſections or nodes, or very near them.

In the nodes, when the moon has no viſible latitude, the occultation is total; and with ſome continuance, when the diſc of the moon, in perigæo, appears greater than that of the ſun in apogæo, and its ſhadow is extended beyond the ſurface of the earth; and, without continuance, at moderate diſtances, when the cuſp, or point of the moon's ſhadow barely touches the earth. Laſtly, out of the nodes, but near them, the *eclipſes* are partial.

The other circumſtances of *ſolar eclipſes* are, 1. That none of them are univerſal; that is, none of them are ſeen throughout the whole hemiſphere, which the ſun is then above; the moon's diſc being much too little, and much too near the earth, to hide the ſun from the diſc of the earth.

The moon's dark ſhadow covers only a ſpot on the earth's ſurface, about 180 Engliſh miles broad, when the ſun's diſtance is greateſt, and the moon's leaſt; and thus far only can the total darkneſs extend. In this caſe, if L (*Tab.* II. *Aſtronomy*, *fig.* 72.) repreſent the moon, T the centre of the earth, LT the diſtance of the moon equal to 56 ſemidiameters of the earth, LM the height of the ſhadow of the moon, equal to 60: then will TB be to TM as 1 to 4, and as the ſine of the angle TMB = 15′ 50″ to the ſine of the angle TBM; i. e. 0,00, &c. : 0,60205999 :: 7,66632969 : 8,26523568, the ſine of 61′ 20″; therefore the arc AB, or the angle ATB = TMB + TBM = 15′ 50″ + 63′ 20″ = 79′ 10″; and the arc BC = 158′ 20″ = 183 miles. But her partial ſhadow, or penumbra, may then cover a circular ſpace 4900 miles in diameter, within which the ſun is more or leſs *eclipſed*, as the places are leſs or more diſtant from the centre of the PENUMBRA. In this caſe the axis of the ſhade is ſuppoſed to paſs through the centre of the earth, or the moon is ſuppoſed to change exactly in the node; and then the ſection of the ſhadow will be evidently circular; but in every other caſe the conical ſhadow is cut obliquely, and the ſection will be an ellipſe.

2. Nor does the *eclipſe* appear the ſame in all parts of the earth, where it is ſeen; but when in one place it is total, in another it is only partial.

Farther, when the moon, being in her apogee, appears much leſs than the ſun, as happens moſt ſenſibly when he is in perigæo; the cuſp of the lunar ſhadow not reaching the earth, ſhe becomes in a central conjunction with the ſun, yet not able to cover his diſc, but leaves his whole limb appear like a lucid ring or bracelet; this is hence called an *annular eclipſe*.

3. It does not happen at the ſame time in all places where it is ſeen; but appears more early to the weſtern parts, and later to the eaſtern.

4. In moſt *ſolar eclipſes* the moon's diſc is covered with a faint, dawning light; which is attributed to the reflexion of the light from the illuminated part of the earth.

Laſtly, in total *eclipſes* of the ſun, the moon's limb is ſeen ſurrounded by a pale circle of light; which ſome attainment take for a manifeſt indication of a lunar atmoſphere; but which is probably the atmoſphere of the ſun; becauſe it has been obſerved to move equally with the ſun, and not with the moon; and beſides, the moon is now generally believed to have NO ATMOSPHERE.

ECLIPSES *of the ſun, aſtronomy of.* To determine the bounds of a *ſolar eclipſe*.

If the moon's parallax were inſenſible, the bounds of a *ſolar eclipſe* would be determined after the ſame manner as thoſe of a *lunar*; but becauſe here is a ſenſible parallax, we muſt alter our meaſures a little, viz.

1. Add the apparent ſemidiameters of the luminaries both in apogæo and perigæo together.

2. Since the parallax diminiſhes the northern latitude, to the former ſum add the greateſt parallax of latitude poſſible, and ſince the parallax augments the ſouthern lati-

tude,

node, from the ſame ſum ſubtract the greateſt parallax of latitude. Thus, in each caſe, will you have the true latitude, beyond which there can be no *eclipſe*.

This latitude given, the moon's diſtance from the nodes, beyond which *eclipſes* cannot happen, is found, as already directed for *lunar eclipſes*.

As different authors follow very different hypotheſes, with regard to the apparent diameters of the luminaries, and the greateſt parallax of latitude, they differ much in aſſigning the bounds at which *ſolar eclipſes* happen. Ptolemy makes the utmoſt bound of *eclipſes* at 19° 25′ diſtance from the node; Copernicus, at 19° 12′; Tycho, at 18° 25′; Kepler at 17° 16′; Ricciolus, at 18° 49′. Though Ptolemy, in other places, judges 16° 42 minutes diſtance from the node, neceſſary; Copernicus, 16° 25′; Tycho, 17° 9′; Kepler, 15° 55′; and Ricciolus, 15° 58′.

Aſtronomers have generally aſſigned 17° as the limit of ſolar *eclipſes*; but this admits of ſome variation; for in apogeal *eclipſes*, the ſolar limit is but 16½ degrees, and in perigeal *eclipſes* it is 18½°.

To find the digits eclipſed. Add the apparent ſemidiameters of the luminaries into one ſum; from which ſubtract the moon's apparent latitude, the remainder is the ſcruples, or parts of the diameter *eclipſed*. Then ſay, as the ſemidiameter of the ſun is to the ſcruples *eclipſed*, ſo are 6 digits reduced into ſcruples, or 360 ſcruples, to the digits *eclipſed*.

To find the ſcruples of half duration, or the line of immerſion. The method is the ſame as that delivered for *lunar eclipſes*.

To determine the duration of a ſolar eclipſe. Find the horary motion of the moon from the ſun, for one hour before the conjunction, and another hour after; then ſay, as the former hotary motion is to the ſeconds in an hour, ſo are the ſcruples of half duration to the time of immerſion; and as the latter horary motion is to the ſame ſeconds, ſo are the ſame ſcruples of half duration to the time of immerſion. Laſtly, adding the time of immerſion to that of emerſion, the aggregate is the total duration.

The moon's apparent diameter when largeſt, exceeds the ſun's when leaſt, only 1 minute 38 ſeconds of a degree; and in the greateſt ſolar *eclipſe* that can happen at any time and place, the total darkneſs can continue no longer than whilſt the moon is moving through 1′ 38″ from the ſun in her orbit, which is about 3 minutes 13 ſeconds of an hour: for the motion of the ſhadow on the earth's diſk is equal to the moon's motion from the ſun, which, on account of the earth's revolution on its axis towards the ſame way, or eaſtward, is about 30½ minutes of a degree every hour, at a mean rate; but ſo much of the moon's orbit is equal to 30½° of a great circle on the earth, becauſe the circumference of the moon's orbit is 60 times that of the earth; and therefore the moon's ſhadow goes 30½ degrees, or 1830 geographical miles in an hour, or 30½ miles in a minute.

To determine the beginning, middle, and end, of a ſolar eclipſe. From the moon's latitude, for the time of conjunction, find the arch IL (*fig.* 35.) or the diſtance of the greateſt obſcurity. Then ſay, as the horary motion of the moon from the ſun, before the conjunction, is to 3600 ſeconds of an hour; ſo is the diſtance of the greateſt darkneſs, to the interval of time between the greateſt darkneſs and the conjunction.

Subtract this interval, in the firſt and third quarter of the anomaly, from the time of the conjunction; and in the other quarters, add it to the ſame; the reſult is the time of the greateſt darkneſs. Laſtly, from the time of the greateſt darkneſs, ſubtract the time of incidence, and add it to the time of emerſion; the difference, in the firſt caſe, will be the beginning; and the ſum, in the latter caſe, the end of the *eclipſe*.

Indeed, as the interval between the conjunction, and the greateſt obſcurity, is very ſmall, and exceedingly precarious, it is not neceſſary to be ſo very preciſe; and accordingly, many authors uſe the time of the apparent conjunction for that of the greateſt darkneſs.

Or if you would determine it with more accuracy, ſubtract about two minutes for the diſtance between the conjuction ſeen, and the time of the greateſt obſcurity.

To find the moon's apparent latitude at the beginning and end of an eclipſe. From the argument of the moon's latitude, computed for the time of the apparent conjunction, ſubtract the ſcruples of half duration, together with the motion of the ſun, anſwering to the time of incidence; the remainder is the argument of latitude, at the beginning of the *eclipſe*.

To the ſame ſum add the ſame ſcruples, together with the ſun's motion anſwering to the time of emergence; the aggregate is the argument of latitude, at the end of the *eclipſe*. The argument of the latitude given, the moon's true latitude is found after the common manner. See LATITUDE. And from the true latitude, is ſoon the apparent one.

The apparent latitude of the moon, at the beginning and end of a ſolar eclipſe, *given; to draw a type or figure thereof.* This is performed, as already taught for *eclipſes* of the moon.

ECLIPSE *of the ſun, to calculate an.* 1. Find the mean new moon, and thence the true one; together with the place of the luminaries for the apparent time of the true one.

2. For the apparent time of the true new moon, compute the apparent time of the new moon obſerved.

3. For the apparent time of the new moon ſeen, compute the latitude ſeen.

4. Thence determine the digits *eclipſed*.

5. Find the times of the greateſt darkneſs, immerſion, and emerſion.

6. Thence determine the beginning, and ending, of the *eclipſe*.

From the preceding problems it is evident, that all the trouble and fatigue of the calculus ariſe from the parallaxes of longitude and latitude; without which, the calculation of *ſolar eclipſes* would be the ſame with that of *lunar* ones. But after all that is here ſaid, it will be found impoſſible to calculate any *eclipſe*, either of the ſun or moon, without having a book of the tables for that purpoſe, and precepts ſhewing how to compute by them. See ſuch tables and precepts in Ferguſon's Aſtronomy, chap. xix.

In the Philoſophical Tranſactions, N° 461. ſect. 9. we have a contrivance to repreſent *ſolar eclipſes*, by means of the terreſtrial globe, by M. Segner, profeſſor of mathematics at Gottingen. And Mr. Ferguſon has fitted a terreſtrial globe, ſo as to ſhew the time, quantity, duration, and progreſs of *ſolar eclipſes*, at any place of the earth where they are viſible. This he calls the ECLIPSAREON. He has alſo given a large catalogue of ancient and modern *eclipſes*, including thoſe recorded in hiſtory, from 721 years before Chriſt, to A. D. 1485; computed *eclipſes* from 1485 to 1700, and all the *eclipſes* viſible in Europe from 1700 to 1800. Aſtron. p. 175, &c.

ECLIPSES, *the number of*, of both luminaries, in any year, cannot be leſs than two, nor more than ſeven; the moſt uſual number is four, and it is rare to have more than ſix. The reaſon is obvious; becauſe the ſun paſſes by both the nodes but once in a year, unleſs he paſſes by one of them in the beginning of the year; in which caſe he will paſs by the ſame again a little before the year be finiſhed; becauſe the nodes move backwards 19½′ every year, and therefore the ſun will come to either of them 173 days after the other. And if either node is within 17° of the ſun at the time of the new moon, the ſun will be *eclipſed*; and at the ſubſequent oppoſition, the moon will be *eclipſed* in the other node, and come round to the next conjunction before the former node is 17° beyond the ſun, and *eclipſe* him again. When three *eclipſes* happen about either node, the like number generally happen about the oppoſite; as the ſun comes to it in 173 days afterwards, and ſix lunations contain only four days more. Thus there may be two *eclipſes* of the ſun, and one of the moon, about each of the nodes. But if the moon changes in either of the nodes, ſhe cannot be near enough the other node at the neat full to be *eclipſed*; and in ſix lunar months afterwards ſhe will change near the other node; in which caſe there can be only two *eclipſes* in a year, both of the ſun.

ECLIPSES, *period of*, is that ſpace of time in which the ſame *eclipſes* return again; and, as the nodes move backward 19½″ every year, they would ſhift through all the ſigns and degrees of the ecliptic in 18 years and 225 days; this would be the regular period of their return, if any complete number of lunations were finiſhed without a fraction; but this is not the caſe. However, in 223 mean lunations, after the ſun, moon, and nodes, have been once in a line of conjunction, they return ſo nearly to the ſame ſtate again, as that the ſame node, which was in conjunction with the ſun and moon at the beginning of the firſt of theſe lunations, will be within 28′ 12″ of a degree of a line of conjunction with the ſun and moon again, when the laſt of theſe lunations is completed; and in this period there will be a regular return of *eclipſes* for many ages. By adding to the mean time of any ſolar or lunar *eclipſe* this period, or 18 Julian years 11 days 7 hours 43 minutes 20 ſeconds, when the laſt day of February in leap years is four times included, or a day leſs, when it occurs five times, we ſhall have the mean time of the return of the ſame *eclipſe*. In an interval of 6890 mean lunations, containing 557 years 31 days 18 hours 30 minutes 12 ſeconds, the ſun and node meet ſo nearly, as to be diſtant only 11 ſeconds.

ECLIPSES, *uſe of*. In *Aſtronomy*, *eclipſes* of the moon determine the ſpherical figure of the EARTH, and alſo that the ſun is bigger than the earth, and the earth than the moon.

moon. *Eclipses* alſo, that are ſimilar in all circumſtances, and that happen at conſiderable intervals of time, ſeem to aſcertain the period of the moon's motion. In *Geography*, *eclipſes* diſcover the LONGITUDES of different places; for which purpoſe thoſe of the moon are the moſt uſeful, becauſe they are more frequently viſible, and the ſame lunar *eclipſe* is of equal magnitude and duration at all places where it is ſeen. In *Cronology*, both ſolar and lunar *eclipſes* ſerve to determine exactly the time of any paſt event.

ECLIPSES *of the ſatellites*. See SATELLITES *of Jupiter*.

The chief circumſtances here obſerved are, 1. That the ſatellites of Jupiter undergo two or three kinds of *eclipſes*; whereof, the firſt are proper, being ſuch as happen when Jupiter's body is directly interpoſed between them and the ſun; theſe happen almoſt every day. Mr. Flamſteed, and Caſſini, give us tables, wherein immerſions into Jupiter's ſhadow, and emerſions again, are computed to hours and minutes.

The ſecond are occultations, rather than obſcurations; wherein the ſame ſatellites, coming too near to Jupiter's body, are loſt in his light; which Riccioius calls *occidere neutrales, ſetting ſpecially*. In which caſe, Jupiter's neareſt ſatellite exhibits a third kind of *eclipſe*; being obſerved like a macula, or dark round ſpot, tranſiting Jupiter's diſc, with a motion contrary to that of the ſatellite; juſt as the moon's ſhadow projected on the earth, will appear to do, to the lunar inhabitants.

The *eclipſes* of Jupiter's ſatellites furniſh the beſt means of finding the longitude at ſea. Thoſe, particularly, of the firſt ſatellite, are much ſurer than the *eclipſes* of the moon, and they alſo happen much oftener; beſide that, the manner of applying them is very eaſy. See LONGITUDE.

ECLIPTIC, ECLIPTICUS, ſomething belonging to eclipſes.

All new and full moons are not *ecliptic*, i. e. eclipſes do not happen every new and full moon, though there be then an interpoſition, either of the earth between the ſun and moon, or of the moon between the ſun and earth. The reaſon is, that the interpoſition is only as to longitude, and not as to latitude. The ſun is always in the *ecliptic*, but the moon is not; ſhe deviates from it above five degrees, and ¼, ſometimes on the north ſide, and ſometimes on the ſouth. But every five months, or thereabouts, ſhe cuts the *ecliptic*; and it is only about thoſe times, that there can be eclipſes either of the moon or ſun.

The places wherein ſhe cuts the *ecliptic*, are called the *nodes* of the moon.

ECLIPTIC *bounds*, or *limits*, are the greateſt diſtances from the nodes at which the ſun and moon can be eclipſed; namely, between 17 and 18 degrees for the ſun, and 12 for the moon.

ECLIPTIC *digits*, *digiti ecliptici*. See DIGITS.

ECLIPTIC is more particularly uſed for a line, or circle, in the ſphere of the ſtars, under which the centre of the ſun apparently proceeds in its proper motion; or a line, which the ſun's centre deſcribes in his annual progreſs.

It has its name *ecliptic*, becauſe all eclipſes happen when the two planets are in or near the nodes, or interſections of the *ecliptic*.

It is alſo called the *ſun's orbit*, and *ſun's way*, becauſe the ſun never deviates from it, in his apparent annual motion from weſt to eaſt.

The north, or aſcending node of the *ecliptic*, is called the *dragon's head*; and the ſouth, or deſcending node, the *dragon's tail*.

The *ecliptic* is placed obliquely with reſpect to the equator, and cuts it in two points, viz. the beginning of Aries and Libra, which are directly oppoſite to each other; and, accordingly, we find the ſun twice every year in the equator; and all the reſt of the year, either on the north or ſouth ſide thereof.

The *ecliptic* is a great circle of the ſphere, biſected by the horizon; conſequently, the arch of the *ecliptic*, intercepted between the horizon and the meridian, is a quadrant. And again, the ſolſtitial points of the *ecliptic*, i. e. thoſe moſt remote from the equator, are a quadrant diſtant from the equinoctial points. Laſtly, as the point of the *ecliptic*, which has the greateſt declination, with reſpect to the equator, is diſtant by a quadrant from the equinoctial points; the diſtance of this point from the equator will be the meaſure, or quantity, of the obliquity of the *ecliptic*, i. e. of the angle, formed by the interſection of the equator with the *ecliptic*.

The obliquity of the ecliptic, or the angle it makes with the equator, is about 23° 28′; which, therefore, is the greateſt declination of any point of the *ecliptic* from the equator; the points of which greateſt declination on each ſide, are called the *ſolſtitial points*; through which are drawn the two tropics, parallel to the equator.

The method of obſerving the greateſt declination of the *ecliptic* is thus: about the time of the ſummer ſolſtice obſerve the ſun's meridian altitude with the utmoſt care, for ſeveral days ſucceſſively: from the greateſt altitude obſerved, ſubtract the height of the equator; and the remainder is the greateſt declination, which is the ſolſtitial point.

Or, it may be found by obſerving the meridian altitude of the ſun's centre on the days of the ſummer and winter ſolſtice; the difference of thoſe altitudes will be the diſtance of the tropics; and half that diſtance will be the obliquity of the *ecliptic*.

Riccioius, e. gr. at Bologna, in the year 1646, obſerved the ſun's meridian altitude, on the 20th of June, to be 68° 59′ 55″; on the 21ſt, 69° 0′ 10″; and on the 22d, 68° 59′ 55″. The greateſt then was, 69° 0′ 10″; from which the altitude of the equator, 43° 29′ 50″, being ſubtracted, left 23° 30′ 20″ for the greateſt declination.

It has been matter of great diſpute among the late aſtronomers, whether the *obliquity of the ecliptic* be fixed or variable. To determine the point, the obſervations of the aſtronomers of all ages have been collected together, the chief of which may be ſeen in the following table.

Author's Names	Years before Chriſt	Obliquity °	′	″

Riccioli Alm. vol. i. lib. iii. cap. 27. Ptolem. Alm. lib. i. cap. 10. Flamſteed Prolog. Hiſt. Cœl. vol. iii. Phil. Tranſ. N° 163. lb. vol. xliii. part i. p. 125. Naut. Alm. 1779. Long's Aſtr. vol. i. cap. 16.

Upon the whole, as the oldeſt obſervations make the obliquity the greateſt, it appears to be mutable, and in a conſtant decreaſing ſtate. The chevalier de Louville, who has examined the merits of the cauſe with great attention, and made allowances for refraction and ſun's parallax, is of the ſame opinion. He gives us the reſult of his reſearches in the Memoirs of the Royal Academy, for the year 1716, viz. that the obliquity of the *ecliptic* diminiſhes at the rate of a minute in 100 years. His diſſertation is publiſhed in Latin in the Acta Erud. Lipſiæ, A. D. 1719.

According to an ancient tradition of the Egyptians, mentioned

mentioned by Herodotus, the *ecliptic* had formerly been perpendicular to the equator: this notion they were led into, by obſerving, for a long ſeries of years, that the obliquity was continually diminiſhing; or, which amounts to the ſame, that the *ecliptic* was continually approaching to the equator. From hence they took occaſion to ſuſpect, that thoſe two circles, in the beginning, had been as far off each other as poſſible. Diod. Siculus relates, that the Chaldeans reckoned 463000 years from their firſt obſervations, to the time of Alexander's entering Babylon. This enormous account may have ſome foundation, ſuppoſing the Chaldeans to have built on the diminution of the obliquity of the *ecliptic* of a minute in 100 years. M. de Louville, taking the obliquity ſuch as it muſt have been at the time of Alexander's entrance into Babylon, and going back to the time when the *ecliptic*, at that rate, muſt have been perpendicular to the equator, actually finds 402942 Egyptian, or Chaldean years, which is only 58 years ſhort of the former epocha. In the general, there is no way of accounting for the fabulous antiquity of the Egyptians, Chaldeans, &c. ſo probable, as from the ſuppoſition of long periods of very ſlow celeſtial motions, whereof they had obſerved a little part, and thence calculated the beginning of the period; making the world and their own nation to commence together. If M. de Louville's ſyſtem be true, in 140000 years more the *ecliptic* and equator muſt coincide.

Godin, in the Memoirs of the Royal Academy for 1734, rejects the concluſions deduced by Louville from the obſervations of ancient aſtronomers, and, by comparing thoſe of Caſſini in 1655, which give the obliquity of the *ecliptic* 23° 29′ 15″, with others made at Paris, and elſewhere, ſince the year 1730, which make the obliquity no more than 23° 28′ 20″, he infers, that it diminiſhes at the rate of 55″ in 80 years, or nearly at the rate of 1′ in 90 years.

Mr. Hornſby, comparing the reſult of his own obſervations, which gives the mean obliquity in 1772, 23° 28′ 8″, with the mean obliquity aſſigned by Mr. Flamſteed in 1690, viz. 23° 28′ 55¾′, concludes, that the obliquity has diminiſhed 47″ in 81 years, or at the rate of 58″ in 100 years; which he obſerves, will be found nearly to correſpond with the mean of the computations framed by Mr. Euler, and Mr. de la Lande, upon the principles of attraction. Other writers have made it ſtill leſs. Phil. Tranſ. vol. lxiii. part i. p. 125.

However, M. Caſſini, and M. le Monnier, are of opinion, that the obliquity of the *ecliptic* hath no other variation than what the mutation of the earth's axis will occaſion. Mem. R. Acad. 1762, & 1767.

But there is reaſon to believe, by comparing the more accurate obſervations in the preceding table, e. gr. thoſe of Ptolemy, Tycho, Flamſteed, Mayer, and Bradley, that the obliquity of the *ecliptic* does gradually decreaſe, and probably at the rate of about half a ſecond in a year. And if we conſider, that the earth is not a perfect ſphere, but an oblate ſpheroid, having its axis ſhorter than its equatorial diameter; and that the ſun and moon are conſtantly acting obliquely upon the greater quantity of matter about the equator, drawing it, as it were, to a nearer and nearer coincidence with the *ecliptic*; it will not appear improbable that theſe actions ſhould gradually leſſen the angle between the planes of theſe circles. Nor is it leſs probable, that the mutual attraction of all the planets ſhould have a tendency to bring their orbits to a coincidence, though the change, being very ſmall, is not ſenſible for many ages. See NUTATION, PRECESSION, and STAR.

The *ecliptic* is divided into twelve parts, called *ſigns*. See SIGN.

ECLIPTIC, *poles of the*. See POLE.

ECLIPTIC, *reduction to the*. See REDUCTION.

ECLIPTIC, in *Geography*, &c. is a great circle of the globe, cutting the equator under an angle of 23° 28′. See GLOBE.

The *terreſtrial ecliptic*, therefore, is in the plane of the *celeſtial ecliptic*; like which it has its equinoctial and ſolſtitial points, and is bounded by tropics.

ECLOGARII, among the *Ancients*, were perſons who ſelected the beſt pieces of the books they read, which, for that reaſon, were called *eclogues*, or ſelect pieces. See ECLOGUE.

ECLOGUE, Ἐκλογη, in *Poetry*, a kind of paſtoral compoſition wherein ſhepherds are introduced converſing together. The *eclogue* is properly an image of the paſtoral life.

The beauty of the *eclogue*, M. Fontenelle obſerves, is not attached to what is rural, but rather to what is calm and eaſy in the rural life.

Yet there are *eclogues* in Theocritus of a lofty character; and Virgil has ſome in the ſublime ſtyle: the *eclogue*, therefore, occaſionally raiſes its voice. Yet M. Fontenelle eſteems it a fault in ſome modern poets, to have put matters of high concern in their *eclogues*, and to have made their ſhepherds ſing the praiſes of kings and heroes. Roſnard, in particular, has made himſelf ridiculous, by giving the *cloſe* of Boadicea and Vatable in his firſt *eclogue*, from the ſhepherd Margot. Such perſons ſhould have been above the knowledge of the ſimple Margot. The ſentiments in *eclogues*, the ſame author obſerves, ſhould be finer and more delicate than thoſe of real ſhepherds; only their form ſhould be as ſimple and rural as can be. But this ſimplicity excludes none befides glaring and exceſſive ornaments.

Since the eſtabliſhment of the academy, or aſſembly of Arcadians at Rome, about the year 1690, the taſte for *eclogues* has been greatly improved among the Italians. Thoſe gentlemen, who are the flower of the wits of Italy, take the name of the ſhepherds of Arcadia, and will not allow their aſſembly to be treated as an academy. They have each of them a poetical name, which is always that of ſome ſhepherd; and apply themſelves particularly to *eclogues*, as pieces moſt proper to their profeſſion. See ACADEMY.

The word *eclogue* is formed from the Greek εκλογη, *choice*. So that, according to the etymology of the word, *eclogue* ſhould be no more than a ſelect or choice piece; but cuſtom has determined it to a farther ſignification, viz. a little elegant compoſition in a ſimple natural ſtyle and manner.

Idyllion and *eclogue*, in their primary intention, are the ſame thing: thus the Idylls, Ειδυλλια, of Theocritus, are pieces written perfectly in the ſame vein with the *Eclogæ* of Virgil.

But cuſtom has made a difference between them, and appropriated the name of *eclogue* to pieces wherein ſhepherds are introduced ſpeaking; idyllion, to thoſe written like the *eclogue*, in a ſimple natural ſtyle, but without any ſhepherds in them. Some imagine the name *eclogue* to have been originally attributed to ſuch poems as were written in imitation of others; ſuch as the *Eclogues* of Virgil, which are only imitations of Theocritus.

Others are of opinion, the word was firſt formed from αιξ, αιγος, goat, and λογος, diſcourſe, q. d. a converſation or diſcourſe of goats, or goatherds. But Rapin, in his notes on Virgil, thinks they would then have made it Αιγολογια, αιγολογη, rather than *eclogue*; or, at leaſt, the word would have been written in Greek with αι, and in Latin by *a*, not *e*.

Barthius advances another opinion; viz. that the name *eclogue* was given to all poetical compoſitions that were of a moderate length, though too ſhort to give them the name of books; and that hence it is that Statius, in the epiſtle at the head of the third book of his Sylvæ, and in the preface to his fourth book call his poems *Eclogues*; though he had not called them ſo in the title.

Auſonius, in the preface to his Cupid crucified, calls alſo his idylls *eclogues*. Add, that Cruquius, in his comment on Horace, declares that he had ſeen very ancient manuſcripts, wherein the ſatires of the poet are called *eclogues*; in which he is ſeconded by our learned countryman, Mr. Baxter.

ECLOGUE is alſo applied to certain compoſitions in proſe. Thus we read of the *eclogues* of Diodorus, of Polybius, of Cteſias, Theophraſtus, Strabo, &c. In which ſenſe the word only ſignifies *extract* or *collection*.

ECLYSIS, from εκλυω, *I faint*, a word uſed by the ancient phyſicians, for a general faintneſs and feebleneſs of all parts of the body. Hippocrates uſes it for a loſs of voice, with a general decay of ſtrength, and, in ſome other places, for a great weakening of the body, by violent diſcharges by ſtool.

ECMARTYRIA, Εκμαρτυρια, in *Antiquity*, a kind of ſecond-hand evidence, admitted in the Athenian courts. It was not founded on the knowlege of the witneſs himſelf, but on that of another perſon, who had been an eye-witneſs of the fact in queſtion, but was at this time either dead, or in a foreign country, or detained by ſickneſs; for, except in ſuch caſes, the allegations of abſent perſons were never taken for lawful evidence. Potter. Archæol. Græc. lib. i. cap. 21. tom. i. p. 117.

ECNEPHIAS, from εκ and νεφος, *a cloud*, a word uſed, by Galen, to expreſs a peculiar ſort of fever, which, he ſays, was at once hot and humid, and which he therefore reſembles, by the name, to the ſun breaking out from a watery cloud.

ECOUIE, in the *Manege*, is uſed for a pace, or motion of a horſe, when he rides well upon the hand and the heels, is compactly put upon his haunches, and hears, or liſtens, to the heels or ſpurs; and continues duly balanced between the heels, without throwing to either ſide. This happens when a horſe has a fine ſenſe of the aids of the hand and heel.

ECPHONESIS, Ἐκφωνησις, in *Rhetoric*, the ſame with EXCLAMATION.

ECPHORA, from εκ, *out*, and φερω, *I bear*, *Projecture*, in

Architecture, uſually denotes the line, or diſtance, between the extremity of a member, or moulding, and the naked of the column, or other part it projects from. Some authors, however, account the *ecphora*, or projecture, from the axis of the column; and define it to be the right line intercepted between the axis and the outermoſt ſurface of a member or moulding. See PROJECTURE.

ECPHRACTICS, Ἐκφρακτικα, in *Medicine*, ſuch remedies as have a faculty of opening and unſtopping the veſſels through which the humours are to paſs; or which incide and attenuate tough viſcid humours, and thereby promote their diſcharge. They are the ſame with *aperients* and *diabſtruents*.

The word is formed from the Greek ἐκφραττειν, *to free from obſtructions*; of ἐκ and φραττω, *obſtruo, ſepio*.

The chief ſimple *ecphractics*, are the little centaury, wormwood, agrimony, hyſſop, chamædrys, bark of tamarik, roots of capers, ſcolopendrium, &c.

ECPHRAXIS, in *Medicine*, is taking away obſtructions in any part. Blancard.

ECPHYSESIS, from ἐκ and φυσαω, *I breathe*, in *Medicine*, is a diſeaſe in which the patient breathes thick.

ECPHYSIS, of ἐκ, and φυω, *I produce*, in *Anatomy*, is any proceſs that coheres with, or adheres to a bone.

ECPIESMA, Ἐκπιεσμα, from ἐκ and πιεζω, *I preſs*, in *Chirurgery*, a kind of fracture of the ſkull, &c. wherein there are ſeveral ſplinters, that preſs and diſorder the inner membranes. See FRACTURE.

ECPIESMUS, Ἐκπιεσμος, in the ancient writers of *Medicine*, a word uſed to expreſs a diſtemperature of the eye, which conſiſts in a very great prominence of the entire globe of the eye, which is, as it were, thruſt out of its ſocket, or orbit, by a great flux of humours, or an inflammation.

ECPLEROMA, of ἐκ and πληροω, *I fill*, in the writings of the *Ancient Phyſicians*, the name given to a kind of cuſhion of leather, ſtuffed with ſome firm ſubſtance, and fitted to the cavities of the arm-pits, uſed in reducing luxations of the humerus.

ECPLEXIS, from ἐκπλησσω, *I am diſturbed*, in the writings of the *Ancient Phyſicians*, a word uſed to expreſs a tranſport of mind, proceeding from ſome ſudden perturbation. Hippocrates and Galen uſe the word to ſignify a ſtupor, or ſtupefaction, in which the patient lies without motion, without ſpeaking, or ſtirring, and with his eyes open.

ECPNEUMATOSIS, in *Medicine*, the ſame with expiration.

ECPNOE, from ἐκ, and πνεω, *I breathe*, a word uſed by medical writers, to expreſs that part of reſpiration, in which the breath is expelled out of the lungs.

ECPTOMA, from ἐκπιπτω, *I fall out*, a word uſed by the ancient phyſicians, in three or four different ſenſes. It is ſometimes made to expreſs a luxation, or diſlocation of a bone. Sometimes it is uſed for the falling off of any corrupted part, ſometimes for the exclusion of the fecundines after child-birth, and ſometimes for a falling down of the womb, or a deſcent of the omentum or the inteſtine into the ſcrotum.

ECTOSIS, in *Surgery*, the ſame with luxation.

ECPUCTICA, from ἐκπυω, *I ſuppurate*, in the *Materia Medica*, are condenſing medicines.

ECREGMA, from ἐκρηγνυμι, *I break off*, properly the name of a part, piece, or ſegment of any thing; but Hippocrates has, in ſome places, uſed it as the name of an eruption.

ECRITHMUS, from ἐκ, *without*, and ῥυθμος, *number*, in *Medicine*, an irregular pulſe, which obſerves no method, nor number, incident to any age. Blancard.

ECSTASIS *cutis*, from ἐκτεινω, *I extend*, an extenſion of the ſkin, a term uſed by the ancients, as the oppoſite to corrugatio, or wrinkling.

ECSTATICI, Ἐκστατικοι, from ἐκστημι, *I am entranced*, in *Antiquity*, a kind of diviners, who were caſt into trances or ecſtaſies, in which they lay like dead men, or aſleep, deprived of all ſenſe and motion; but, after ſome time, returning to themſelves, gave ſtrange relations of what they had ſeen and heard. Pott. Archæol. Græc. lib. ii. cap. 12. tom. i. p. 302.

ECSTROPHIUS, from ἐκστρεφω, *I turn out*, a name given by the ancient writers in medicine, to any thing that threw out the internal tumors of the piles, ſo that external remedies might be applied to them.

ECTHESIS, in *Church-Hiſtory*, a name which the emperor Heraclius gave to a confeſſion of faith publiſhed by him in 639.

The word is Greek, ἐκθεσις, and ſignifies *expoſition*.

The *ecthoſis* favoured the error of the Monothelites, and eſtabliſhed only one will and one operation in Jeſus Chriſt. Heraclius publiſhed it at the inſtigation of Athanaſius, chief of the Jacobites, Cyrus patriarch of Alexandria, and Sergius patriarch of Conſtantinople; but the Roman church eſteemed it heretical, rejected it in a council held at Rome, A. D. 639, under the pontiff John IV. though Honorius, in ſpite of his infallibility, had approved it; and another edict was iſſued, ſuppreſſing the *ecthoſis*, called the τυπος, which ſoon after ſhared the ſame fate.

ECTHLIMA, from ἐκθλιβω, *I preſs out*, an ulceration ariſing from a violent compreſſion in the ſurface of the ſkin.

ECTHLIPSIS, in the *Latin Proſody*, a figure whereby an *m* is retrenched, or cut off, chiefly at the end of a word, when the following word begins with a vowel, or an *h*.

The word is Greek. ἐκθλιψις, which ſignifies *eliſion*.

Thus, in *multum ille, & terris jactatus & alto*. Virg. In ſcanning the verſe, we drop the *m* at the end of *multum*, and only make three ſyllables in the two firſt words, *multi-ille*.

Some account the *ecthoſis* a poetical licence in the Latin verſification; but, in reality, the eliſion of an *m* final, when the following word in the ſame verſe begins with a vowel, is a matter of neceſſity, not of licence.

Anciently, the *s* was likewiſe retrenched before a conſonant; as *facunda ſuaque*, for *facundus*, &c. In reality, the *m* and *s* were peculiarly rough and harſh in the Latin pronunciation; as appears from Quintilian; and it was this that led the poets to retrench them at the ends of their words; as the like cauſe induced the French to drop their *e* feminine before a word beginning with a vowel, to avoid the hiatus, or concourſe of vowels.

ECTHYMA, from ἐκθυω, *I break out*, a name given by Hippocrates to any puſtule, or cutaneous eruption.

ECTHYMOSIS, of ἐκ, *ex*, and θυμος, *animus, mind*, in *Medicine*, a vehement agitation and dilatation of the blood and ſpirits; ſuch as happens in extraordinary emotions of joy.

ECTOMIAS, from ἐκτεμνω, *I cut off*, a name uſed by the ancient phyſicians, to expreſs a caſtrated animal.

ECTRIMMA, from ἐκτριβω, *I rub off*, excoriation or galling. Hippocrates has uſed the word particularly to expreſs exulcerations of the ſkin about the os ſacrum, contracted by lying long in one poſture, in caſes of fractures of the thigh, or in lingering illneſſes, in which the patient is confined to his bed for a long time.

ECTROPIUM, from ἐκτρεπω, *I turn out*, in *Surgery*, that diſtemperature of the eye-lids, in which they are everted or retracted, ſo as to ſhew their internal or red ſurface, and cannot ſufficiently cover the eye. Sometimes this is a ſimple and original diſorder, and ſometimes it is only a ſymptom of ſome other, as of an inflammation, ſarcoma, tumor, or the like. This ſometimes owes its original to the contraction of the ſkin of the eye-lids, by the ſcar of a wound, ulcer, burn, &c. or to the induration and contraction of the ſkin, after an inflammation, and ſometimes it in a great meaſure proceeds from the injudicious uſe of aſtringent collyriums, or eye-waters.

When this diſorder is become inveterate, it is not eaſily cured; while recent, it is to be attempted by relaxing and elongating the ſkin of the eye-lid, by the application of emollients, ſuch as the vapors of hot milk, or water, oil of almonds, mucilage of quince-ſeed, and ointment of marſhmallows. Theſe muſt be repeated every day, the ſkin of the eye-lid drawn frequently towards its right poſition, and when the patient goes to bed, the eye-lids ſhould be brought together, and reſtrained in their proper poſture by a plaiſter, compreſs and bandage. But if all this fail, and the caſe yet appear not incurable, manual operation muſt take place.

The operation is performed in the following manner: firſt a ſemilunar incition is to be made in the external ſkin of the eye-lid, next its tarſus, or cartilaginous margin, making the angles of the inciſion, downward in the upper lid, and upward in the under, that by this means the ſkin may be elongated. If it does not appear ſufficiently let out by one inciſion, two or three more may be made, running parallel with the firſt, and at the diſtance of a ſmall parkithread. When the eye-lid is thus ſufficiently elongated, the inciſions muſt be dreſſed firſt with dry lint ſtuffed into them, and afterwards with lint, armed with ſome vulnerary unguent, which will prevent the ſkin from growing together again, and will occaſion new fleſh to be formed in the place, which will elongate the ſkin. Laſtly, to forward the extenſion and cure, a piece of ſticking plaiſter ſhould be faſtened to the eye-lid, to keep it extended, and this muſt be continued till the eye will ſhut cloſe. When this caſe has continued from the patient's birth, the cure is very difficult, and it is a yet more hopeleſs caſe, when it happens to old people, from a weakneſs of the orbicular muſcle. Heiſter's Surgery, p. 372.

ECTROTICA, from ἐκτιτρωσκω, *I cauſe to miſcarry*, a name given, by the ancient phyſicians, to ſuch medicines as have a power to occaſion abortion.

ECTYLOTICS, Ἐκτυλωτικὰ, from ἐκ, and τύλος, *callus*, remedies proper to consume and eat off calluses, warts, and other excrescences, formed on the flesh.

ECTYPE, Ἔκτυπος, among *Medallists*, an embossed figure, or impression of a seal, ring, or medal; or a figured copy of an inscription, or other ancient monument.

The word is Greek: ἀρχέτυπον denotes the *original*, or *model*; ἔκτυπον, the *copy*, or *image*, moulded or struck in *cream*; and ἔκτυπον, *ectypon*, the image in *relievo*, or *embossed*.

ECTYPE *Craticular*. See ANAMORPHOSIS.

ECU, or ESCU, the French crown. See CROWN, ESCU, and COIN.

ECU *ancient*, in *Heraldry*, a term signifying the ancient shield. By this they mean the antique triangular-shaped shield, on which the arms of the noble families of France have been painted. This shield is to be seen on old gems, and some ruins; but the modern shield, which is square, and rounded and pointed at the bottom, has banished the use of this.

ECURIE, in the *Manage*, the covert place for the lodging or housing of horses. The word is French. We use *stable* in common discourse.

ECURY. See EQUERY.

ECUSSON, in *Heraldry*, an inescutcheon, or little escutcheon. See ESCUTCHEON.

ECUYER, in the French *Manage*, is used for the riding-master. Sometimes it denotes certain officers in the king of France's houshold, who help the king in mounting his horse and alighting, and follow him on horseback, and carry his sword. These are called *ecuyers de quartier*. Gentlemen-ushers to the queen of France, and the masters of the horse to princes, and persons of quality, are also called *ecuyers*. Besides these, there are others called *ecuyers cavalcadours*. See CAVALCADOUR.

ECZEMA, from ἐκζέω, *I am externally hot*, a name given, by the ancient physicians, to any fiery pustule on the skin.

EDDA, in *Antiquities*, is a system of the ancient Icelandic, or Runic mythology, containing many curious particulars of the theology, philosophy, and manners, of the northern nations of Europe; or of the Scandinavians, who had migrated from Asia, and from whom our Saxon ancestors were descended. Mr. Mallet apprehends that it was originally compiled soon after the Pagan religion was abolished, as a course of poetical lectures, for the use of such young Icelanders as devoted themselves to the profession of a *skald* or poet. It consists of two principal parts; the *first* containing a brief system of mythology, properly called the *Edda*; and the *second* being a kind of art of poetry, and called *Skaldu*, or *Poetics*. The most ancient *Edda* was compiled by Soemund Sigfusson, surnamed the *Learned*, who was born in Iceland about the year 1057. This was abridged, and rendered more easy and intelligible, about a hundred and twenty years afterwards, by Snorro Sturleson, who was supreme judge of Iceland in the years 1215 and 1222; and it was published in the form of a dialogue. He added also the second part in that form of a dialogue, being a detail of different events transacted among the divinities. The only three pieces that are known to remain of the more ancient *Edda* of Soemund, are the Voluspa, the Havamaal, and the Runic chapter. The Voluspa, or prophecy of Vola or Fola, appears to be the text, on which the *Edda* is the comment. It contains in two or three hundred lines the whole system of mythology, disclosed in the *Edda*, and may be compared to the Sibylline verses, on account of its laconic yet bold style, and its imagery and obscurity. It is professedly a revelation of the decrees of the Father of nature, and the actions and operations of the gods. It describes the chaos, the formation of the world, with its various inhabitants, the functions of the gods, their most signal adventures, their quarrels with Loke, their great adversary, and the vengeance that ensued; and concludes with a long description of the final state of the universe, its dissolution and conflagration, the battle of the inferior deities, and the evil beings, the renovation of the world, the happy lot of the good, and the punishment of the wicked. The Havamaal, or *Sublime Discourse*, is attributed to the god Odin, who is supposed to have given these precepts of wisdom to mankind; it is comprized in about a hundred and twenty stanzas, and resembles the book of Proverbs. Mr. Mallet has given several extracts of this treatise on the Scandinavian ethics. The Runic chapter contains a short system of ancient magic, and especially of the enchantments wrought by the operation of Runic characters, of which Mr. Mallet has also given a specimen. A manuscript copy of the *Edda* of Snorro is preserved in the library of the university of Upsal; the first part of which hath been published with a Swedish and Latin version, by M. Gorauseu. The Latin version is printed as a supplement to Mr. Maller's Northern Antiquities. The first edition of the *Edda* was published by Resenius, professor at Copenhagen, in a large quarto volume, in the year 1665; containing the text of the *Edda*, a Latin translation by an Icelandic priest, a Danish version, and various readings from different MSS. Mr. Mallet has also given an English translation of the first part, accompanied with remarks; from which we learn, that the *Edda* teaches the doctrine of the Supreme, called the Universal Father, and Odin, who lives for ever, governs all his kingdom, and directs the great things as well as the small; who formed the heaven, earth, and air; made man, and gave him a spirit or soul, which shall live, after the body shall have mouldered away; and then all the just shall dwell with him in a place called *Gimle* or *Vingolf*, the palace of friendship; but wicked men shall go to *Helia*, or death, and from thence to *Nifleim*, or the abode of the wicked, which is below the ninth world. It inculcates also the belief of several inferior gods and of goddesses, the chief of whom is Frigga, or Frea, i. e. *lady*, meaning hereby the earth, who was the spouse of Odin, or the Supreme God; whence we may infer that, according to the opinion of these ancient philosophers, this Odin was the active principle or soul of the world, which uniting itself with matter, had thereby put it into a condition to produce the intelligences, or inferior gods, and men, and all other creatures. The *Edda* likewise teaches the existence of an evil being, called Loke, the calumniator of the gods, the artificer of fraud, who surpasses all other beings in cunning and perfidy. It teaches the creation of all things out of an abyss or chaos; the final destruction of the world by fire; the absorption of the inferior divinities, both good and bad, into the bosom of the grand divinity, from whom all things proceeded, as emanations of his essence, and who will survive all things; and the renovation of the earth in an improved state. Fables 1. 2. 10. 16. 33. For a farther account of the *Edda*, see Mallet's Northern Antiquities, vol. ii. 1770. passim.

EDDISH, or EADISH, the latter pasture, or grass, which comes after mowing, or reaping; otherwise called *eartgrass*, *eesse*, and *etch*.

EDDY, Sax. of *ed*, *backward*, and *ea*, *water*, in *Sea Language*, is when the water, at any place, runs back, contrary to the side, or stream, and so falls into the current again.

The seamen call that *eddy water* which falls back, as it were, on the rudder of a ship under sail, the *dead water*. An *eddy wind* is that which returns, or is beat back, from any sail, &c.

EDELING. See EDHILING, and ATHELING.

EDESSENUM, the name of a famous collyrium, reckoned among the number of the *monobemira*, or such as cured certain disorders of the eyes, in one day. It is supposed to have had its name *Edessenum* from the city of Edessa, where it was first invented, and in great use. Its composition was this: take gum arabic, tragacanth, sarcocolla, acacia, and starch, of each two drams; opium, four drams; cerusse, eight drams; cadmia, fifteen drams; these were all to be reduced to a fine powder, and afterwards mixed with a sufficient quantity of water, to be used to wash the eyes.

EDGE *in work a ship*, in the *Sea Language*, is said of a chace, that is making up to it.

EDGE *away*, is to decline gradually from the shore, or from the line of the course which the ship formerly steered, when she sails nearer the direction of the wind, or *larger* before the wind.

EDGINGS, in *Gardening*, rows of shrubs, herbs, or flowers, placed by way of borders around beds, compartments, &c. For the *edgings* of compartments, box seems the most proper. See BOX.

EDHILING, EDHILINGUS, an ancient appellation of the nobility among the Anglo-Saxons.

The Saxon nation, says Nithard, Hist. lib. iv. is divided into three orders, or classes of people; the *edhilingi*, the *frilingi*, and the *laxti*; which signify the nobility, the freemen, and the vassals or slaves.

Instead of *edhilings*, we sometimes meet with *athelings*, or *atheling*; which appellation was likewise given to the king's son, and the presumptive heir of the crown. See ATHELING.

EDICT, an instrument, signed and sealed by a prince, to serve as a law to his subjects.

Edicts have no room in England, where the enacting of laws is not lodged in the king, but in the parliament.

In the Roman law we find frequent mention of the *edict of the prætor*, *quod prætor edixit*, which was a phrase appropriated to the ordinances of the prætor; though it was sometimes also used on other occasions.

In the French law, *edicts*, *edits*, make a great figure; they are of various kinds; some importing a new law, or regulation,

gulation, as the *edict* of duels, that of second marriages, &c. Others the erection of new offices, eſtabliſhment of duties, rents, &c. Sometimes articles of pacification, as the *edict* of Nantz, paſſed by Hen. IV. in 1598, and revoked by Louis XIV. in 1685, &c.—*Edicts* are all ſealed with green wax, to ſhew that they are perpetual and irrevocable.

Edicts with them are much the ſame as proclamations with us; but with this difference, that the former have the authority of a law in themſelves, from the power which iſſues forth; whereas the latter are only declarations of a law, to which they refer, and have no power in themſelves.

EDICT, *chamber of the.* See CHAMBER.

EDIFICE, ÆDIFICIUM, a building. See BUILDING.

The word is formed of the Latin, *ædes* and *facio*, *I make*.

EDILE, or rather ÆDILE. See ÆDILE.

EDITOR, of *edo*, *I publiſh*, in the commonwealth of learning, a perſon who takes care of publiſhing the work of another author, uſually an ancient author.

Eraſmus was a great *editor* of ancient writings; the Louvain doctors, Scaliger, Petavius, Fa. Sirmond, biſhop Walton, Mr. Hearn, &c. are learned *editors*; the Benedictines, of the fathers, the Dauphins; of the claſſics; Hardouin, of the Councils, &c.

EDUCATION, the art of bringing up, forming, and inſtructing children.

The follies of a too delicate *education* are well expreſſed in that device of an ape; which, by over careſſing and hugging its young ones, ſtrangles them; with this motto, *complectendo necat*. Octavius Ferrarius has a very good Latin treatiſe on the ſubject of *education*, intitled *Chiron*; the name of the centaur who was Achilles's tutor.

Mr. Locke's excellent treatiſe of *Education* is known to every body. Quintilian employs the ſecond chapter of his firſt book in enquiring whether a domeſtic, or a college, *education* be preferable, i. e. whether it be better to bring up one's children at home, or ſend them to the colleges and public ſchools. After urging all that can be ſaid on either ſide, he concludes for a college or ſchool *education*.

The plan of *education*, whether it be domeſtic or collegiate, ſhould be ſuited to the ſtation and views of parents, and to the genius of their children; and it is alſo right to conſult their conſtitution and inclination. It is of great importance, that thoſe who are deſtined to occupy ſuperior ſtations in ſociety, ſhould enjoy the benefits of an enlarged and liberal *education*; that they ſhould be furniſhed with every ſubſtantial and ornamental accompliſhment; and thoſe that are intended for any particular profeſſion or employment ſhould be principally directed to thoſe ſtudies which are appropriated to their reſpective views; and in every rank of life, an attention to the morals of youth ſhould be a primary object. Though the municipal laws of moſt countries have made no proviſion for conſtraining a parent to beſtow a proper *education* on his children; yet in the caſe of religion they are under peculiar reſtrictions in our own country. Some of theſe reſtrictions, as they affect proteſtants who diſſent from the religion of the ſtate, may be thought both impolitic and injurious, and have, therefore, lately been conſiderably relaxed; but thoſe which are deſigned to prevent the progreſs of popery are prudent and neceſſary. Thus, if any perſon ſends a child under his care beyond the ſeas, to be inſtructed in any popiſh college, &c. in the principles of the popiſh religion, or ſhall contribute towards his maintenance, he ſhall forfeit one hundred pounds, beſides the diſabilities incurred by the child ſo ſent. 1 Jac. I. cap. 4. and 3 Jac. I. cap. 5. 11 and 12 W. III. cap. 4 and both ſhall be incapable of ſuing in law or equity, of being executor or adminiſtrator, of enjoying any legacy or deed of gift, or of bearing any office in the realm; and he ſhall forfeit all his goods and chattels, and likewiſe all his real eſtate for life. 7 Car. I. cap. 2.

EDULCORATION, of *edulco*, *I ſweeten*, in *Pharmacy*, is the dulcifying or ſweetening of any food, or remedy, by means of honey, ſugar, or ſyrups.

EDULCORATION, in *Chemiſtry*, denotes the freſhening or purging of any thing of its ſalts, by repeated lotions, or waſhings in cold water.

Such is the dulcifying of the precipitates of mercury, metals, &c. by waſhing away thoſe ſharp ſalts, by whoſe means they had been diſſolved, or which had been mingled with them, to effect a diſſolution. See ABLUTION.

EDULCORATION, in *Metallurgy*, is the ſeparating, by a ſolution in water, of the ſalts that have been left adhering to a body after any operation. This is properly a kind of moiſt ſolution, the ſaline parts adhering to bodies, not ſoluble in water, being by that menſtruum taken up, and eaten off from the body, and the ſolution afterwards ſeparated from the remaining ſolid, either by ſubſidence or filtration.

It is proper, in this ſituation, to enlarge the ſurface of the body to be edulcorated, by pounding it in a mortar, that the ſolution may have the ſpeedier ſucceſs; and for this purpoſe, it ſhould alſo be kept continually ſtirring with a ſtick, while the water is on it, that all the parts of the body to be edulcorated which otherwiſe would ſome of them ſink to the bottom and remain applied againſt the bottom of the veſſel it is performed in, may be made equally at one time or other contiguous to the particles of the edulcorating fluid, by which all ſolutions are indeed greatly facilitated. Boiling water is alſo, in ſome caſes, requiſite; for the heat of that, by the inward motion and rarefaction it occaſions, promotes, in an extraordinary manner, ſaline ſolutions.

A perfect ablution from the ſalt, however, is not always obtained by this method; for as every part of the menſtruum contains in it a proportionable quantity of the matter diſſolved; and there remains always ſome part of the menſtruum thus impregnated in the body to be edulcorated, it is evident that there alſo remains in it the proportionable quantity of ſalt for that menſtruum. Let us take, for inſtance, the alkaline ſalt in wood-aſhes, pour hot water on ſuch aſhes, and let them boil together for ſome time; then by decantation, or otherwiſe, ſeparate the ley or water impregnated with the ſalt of the aſhes, from the aſhes themſelves; there will remain, after all you can do to pour it off, at leaſt one-fourth part of the ley among the aſhes, and of courſe a proportionable part of the diſſolved ſalt. Pour more water on this, and decant it off again, a quantity of ſalt, though much leſs than the former, will again remain; and ſo on, if the operation be repeated ever ſo often; only the ſalt will be in leſs and leſs quantity every time. Very frequent repetitions of this operation are therefore always neceſſary; and even where the operator has tired himſelf with them, a nice experimenter will always find ſome ſmall portion of the ſalt remaining.

To this remaining of the ſaline particles, in ſome degree, after ever ſo often repeated waſhings, is owing the great loſs artificers uſually find in reducing the calxes of gold and ſilver, made with acids. For the ſmall remainder of the acids which yet adhere, being agitated by an impetuous, and eſpecially by an open fire, carry off in their evaporation a great many particles of the metals with them, not even excepting aqua fortis itſelf, which is ſaid to be, nay, and really is, of a fixing nature, but that only in a certain degree. Cramer, Art. of Aſſ. 306.

EDYSTONE *light-houſe*, lying off Plymouth harbour, was firſt erected by the corporation of the Trinity-houſe in 1696; in conſideration of which, the maſters, &c. of Engliſh ſhipping agreed to pay one penny a ton outwards and inwards. It was demoliſhed by the ſtorm of 1703, and re-erected by act of parliament in the 4th of queen Anne, and the ſame duty on tonnage of ſhips granted for its ſupport, which law was enforced in the 8th of Anne. It has been ſince deſtroyed and rebuilt.

EEL, *anguilla*, in *Ichthyology*, a ſpecies of the MURENA. The common *eel* is the ſimple coloured *muræna*, with the lower jaw longeſt: it has three fins, viz. two pectoral, ſtanding on each ſide, and a ſingle low back-fin, which beginning at ſome diſtance from the head, runs along the back to the tail, and returns again underneath as far as the *anus*. The extremity of this fin, which forms what may be called the tail, is neither round nor ſquare, but ſubacute. *Eels* vary much in their colour, from a ſooty hue to a light olive-green; and thoſe which are called ſilver *eels*, have their bellies white, and throughout a remarkable clearneſs. See GRIGS.

The *eel* is common in all our freſh waters, ponds, ditches, and rivers; and is generally about two feet in length, though ſome are often caught much larger.

The fat of *eels* is accounted vulnerary, and good in an *alopecia*, caſes of deafneſs, and the hæmorrhoids. The dried livers and galls of *eels*, are recommended by Mr. Boyle, to aſſiſt women in hard labour. Boyle's Works, Obſ. vol. i. p. 93.

Eel-fiſhing is of divers kinds, as ſnigling, bobbing, &c. See FISHING.

There is ſcarce any animal, the generation of which has ſo much perplexed and puzzled the thoughts of the learned and curious as this. Ariſtotle firſt gave birth to an opinion, that *eels* were of no ſex, nor did propagate their ſpecies like other animals, but were equivocally gendered of the mud; and as wild and abſurd a ſyſtem as this is, there have not been wanting many, even in thoſe later and more enlightened times, who have given into it. The preſent age has been ſo well inſtructed in the ſyſtem of animal generation, by the works of Swammerdam, Leewenhoeck, Malpighi, Redi, Ray, and a great number

ber of other writers, of the same valuable kind, that there is left no room to doubt but all animals are produced by the copulation of parents like themselves; and the oddity of *eels* being found in new ponds is easily accounted for, when we know that Dr. Plott, and many others, have given accounts of whole droves of them leaving one ditch or pond, and crossing the meadows together to go to another. We know that the *eel*, of all the fishes, lives the longest out of water; and it is not difficult to conceive, that it may, without any inconvenience, spend so much time out of that element as is necessary for the passing from one water to another; and when a number of these fishes have found a new pond, it is no wonder that they continue in it, since they feed on worms and other insects of the earth; and there is probability that these may be found in peculiarly great abundance in the place where the earth has been newly disturbed, and where they have not been preyed upon.

Though the learned world at this time generally allows, that *eels* are produced like other animals, by parents of their own kind, yet there remain many doubts about the manner in which this is performed; some allowing the *eels* to be like the generality of other animals, of different sexes in the different individuals; and others affirming that they are all hermaphrodites, each having the parts of generation of both sexes. Rondeletius affirms, they are of different sexes; and Mr. Allen, who has given a very curious paper concerning them, in our Philosophical Transactions, is of the same opinion; and both say, that the parts of the sexes may be discovered, on a carefull inspection, and some found to be males and others females: but these parts are, in both sexes, they say, buried in a large quantity of fat; and they are of opinion, that hence proceeded the mistake of Aristotle and his followers, who, not being able to find these parts, concluded that they did not exist at all.

Among those who allow the *eel* to be produced like other animals, from animal parents, which have the sexes, some are of opinion that they are viviparous; and others, that they are oviparous: but a gentleman of our nation, Mr. Chartwynd, seems to have determined this great controversy, by observing, that if the aperture under the belly of the *eel*, which looks red in the month of May, be cut at that time, the young *eels* will be seen to come forth alive, after the operation. Mr. Leewenhoeck says that he found an uterus in every *eel* he examined; and therefore concludes, that they are hermaphrodites; and he supposes that they have no male parts of generation, like those of other animals, but that the office of these is performed by a liquor analogous to the male seed of animals, which is contained in certain glands, situated on the inside of the uterus itself.

The conger, or *sea-eel*, usually grows to a very great bigness; but the common fresh-water *eel* seems intended to have been limited to a certain small size; yet, at times, there have been caught some which have greatly exceeded this their seemingly stated limit. The common size of the CONGER, or *sea-eel*, see *Tab. Fish. fig.* 11. at full growth, is the length of nine or ten feet, and the thickness of a man's thigh; and, when of this size, they will weigh from thirty to forty, or fifty pounds; though Salvian says, they usually do not exceed thirty. Strabo tells us of some of them growing to eighty pound weight; but, by what we see of them, there is reason to believe, that between twenty-five and thirty pounds weight seems their natural stint, at full growth; and that those which so exceed it, are like the monstrous common *eels*, accidentally increased to a preternatural bulk. Pliny and Solinus talk of *eels* of thirty feet long; but the largest we find, even of our monstrous ones, come greatly short of that. The conger always has a sort of barbs; and an *eel* that has not those, may always be assuredly known by that character alone, to be a true fresh-water *eel*, though ever so large. Of this kind, the Thames, and some other rivers about London, seem to have furnished the largest of any part of Europe. Mr. Dale commemorates the taking of two of these, in the Philosophical Transactions; the one near Cricksea in Essex was five feet five inches long, and measured twenty-two inches round. The weight of this was about twenty pounds, which is the stint that Aldrovand gives to the fresh-water *eel*, saying, that they sometimes, though very rarely, do come up to this, but that they never exceed it. The other was caught near Maldon, and was seven feet long, twenty-seven inches in circumference, and its weight was thirty pounds. Out of its back and belly there were taken five pounds of fat. This creature seemed to have been brought down the river by the violence of some land flood, and was in a wounded condition when taken by the fishermen, having a hart upon its back, which it seemed to have got in passing through some mill. Both this and the other were evidently freshriver *eels*: and long since these, so lately, indeed as in the year 1748, one of these large *eels* was taken at Limehouse, where it was left on shore by the tide; it was five feet six inches long, and as thick as a man's thigh; its weight was twenty-seven pounds.

EEL, *Electrical*. See GYMNOTUS.

EEL, *Indian, anguilla Indica*, in *Ichthyology*, the name of the East Indian *eel*, of which there are two kinds, the one all over spotted with brown, and the other of a fine yellow colour, streaked with red. The flesh of this is not accounted wholesome.

EEL, *Sea, anguilla marina*, a fish common under holes of rocks, about the shores in many parts of the East Indies. It is of a dusky brown colour, variegated with rhomboidal spots not unlike those on the skins of snakes. The anterior part of its body is thin and slender, the hinder part very thick; its nose is long, its mouth large, and commonly gaping open, and its teeth very sharp, but very small. It grows extremely fat, and is very wholesome and well tasted; yet those who kill a number of them are said to be affected with tremors, and sometimes with a drowsiness, which however goes off without farther mischief.

EELS, *microscopic, in sour paste*. The long-bodied animalcules, discovered by the microscope in vinegar, sour paste, and many other subjects, have, from their figure, been generally distinguished from the rest of the microscopic animalcules, by the name of *eels*. These, and the other kinds, have been, by the most judicious naturalists, supposed to be produced of the eggs of other animalcules of the fly kind, floating in the air. But those in paste are discovered to be viviparous animals, producing living creatures of their own shape. In order to be always furnished with these minute *eels* ready for the microscope, take such paste as book-binders commonly use, of a moderate consistence, and expose it to the air in an open vessel, and prevent its becoming hard or mouldy, by occasionally stirring it. After some days it will turn sour; and, if examined attentively, you may discern multitudes of exceedingly small, long, slender, wriggling animalcules, which grow larger daily, till you will be able to see them with the naked eye. In order to promote their coming forward, pour now and then a drop of vinegar on the paste, and then they may be preserved all the year: the continual motion of these animalcules will contribute to prevent any mouldiness in the paste, which is best kept in some glass vessel. Apply them to the microscope on a single tale or slaughs, after having first put upon it a small spot of water for them to swim about in; the internal motion of their bowels may be plainly perceived; and when the water is almost dried away, and they are nearly expiring, their mouths may be seen opening to a considerable width. On cutting one of these paste-*eels* in two across the middle, a long and slender tube is seen to shoot out from each of the divided ends, and a number of seeming ova issue from this; but these, examined strictly, appear to be living *eels* of different growths, and all included in their proper membranes; some move themselves but slowly, while others coil and uncoil themselves pretty briskly; and the most mature are seen to make strong efforts towards the disengaging themselves of their enveloping membranes, and at length succeed, and swim at liberty, like their parent animal. The tube thrust out each way, on dividing the body, is properly the uterus of the animal, which in the larger *eels* is seen to be full of dark spots, that are the embryo *eels*; and these dark spots are also to be observed in the young ones, as soon as produced. Phil. Trans. N° 478. p. 13. and vol. xlii. p. 67 and Baker's Microsc. 1743. p. 81, &c. See ANIMALCULE.

EELS *in vinegar*. See VINEGAR.

EEL-*fares*, is used for the fry or brood of *eels*. Stat. 25. Hen. VIII.

EEL-*pout*, in *Ichthyology*, the English name of the mustela fluviatilis, a fish of the gadus kind, according to Artedi, and distinguished from the others by the name of the bearded gadus, with two fins on the back, and with both jaws of the same length. See GADUS.

This fish is caught in the Trent, and many other of our rivers, and in some places called a burbot, and is a very delicate fish for the table.

The name is derived from the German *aal-put*, which is in that language the name of the same fish, and is compounded of the words *aal*, *an eel*, and *put* or *padd*, *a frog*; so that the English word should properly be the *eel-frog*. It is commonly, when full grown, about fourteen inches long, and is slender in proportion to its length, and something of the *eel*-shape, but too short for its thickness, to be truly so. It is very soft and slippery to the touch, like the *eel*, and is covered either merely with a slimy matter, or else with extremely minute scales. It is of the colour of a tench; its head is large and flat, its nostrils small and round, and its jaws beset with very

small teeth, which make them feel rough like a file; and there is, beside these, a semicircular spot in the palate, rough in the same manner. There are two fins on the back, and one on the belly, reaching from the anus to the tail; and it has a little beard from the extremity of the lower jaw, and between the nostrils and end of the snout, two others, and seven gills. Willughby's Hist. Pisc. p. 125. There is another variety of *eel-pout*, which Linnæus has made a species of BLENNIUS: these are viviparous, and bring forth two or three hundred young at a time, a little after the depth of winter. They are common in the Esk, at Whitby, in Yorkshire, and are a coarse fish.

EEL-*spear*, a forked instrument with three or four jagged teeth, used for catching *eels*; that with four teeth is the best. This is struck into the mud at the bottom of the river; where, if it strikes against *eels*, it is sure to bring them up.

EEL-*backed*, a term used by the dealers in horses, for such as have black lists along their back.

EFFAIRE, or EFFARE, *in Heraldry*, a term applied to a beast, when rearing on his hind legs, as if it were affrighted.

EFFECT, the result or consequence of the application of a cause, or agent, on some subject.

It is one of the great axioms of philosophy, that full or adequate *effects* are always proportionable to the powers of their causes.

EFFECT is also of some farther import in the arts; as when we say in *Painting* and *Architecture*, that such a contrast, or such a drapery, or such an attitude, have a fine or an ill *effect*, i. e. are beautiful, noble, or the contrary. Too many breaks, and little enrichments, in a building, have a poor *effect*, i. e. they give it a mean aspect.

EFFECT, in the *Manage*, is applied to the motions of the hand which direct the horse.

They distinguish *four effects* of the hand, viz. in using the bridle to put a horse forwards, draw him backwards, and shifting it out of the right hand into the left, or *vice versa*.

EFFECTS, in *Commerce*, &c. the goods possessed by any person, whether moveable or immoveable; particularly those which merchants and dealers acquire by trade. See CHATTELS.

The *effects* of merchants are usually distinguished into three classes, good, bad, and doubtful. By an ordonnance of the French court in 1673, every merchant is obliged to take an inventory or review every year, of all his *effects* of every kind.

EFFECTS, *Vicount*. See VICOUNT.

EFFECTIONS, in *Geometry*, the geometrical constructions of propositions.

The term is also used in reference to problems and practices; which, when they are deducible from, or founded upon some general propositions, are called the *geometrical effections* thereof.

EFFECTIVE *men*, in *Military-language*, are soldiers fit for service.

EFFEMINATE, *effeminati*, according to the Vulgate, are mentioned in several places of scripture. The word is there used to signify such as were consecrated to some profane god, and prostituted themselves in honour of him.

The Hebrew word, *kedesh*, translated *effeminatus*, properly signifies *consecrated*, and hence was attributed to those of either sex, who publicly prostituted themselves in honour of Baal and Astarte.

Moses expressly forbids these irregularities among the Israelites; but the history of the Jews shews, that they were notwithstanding frequently practised. Levit. xxiii. 18. Calmet. Dict. Bibl. in voc.

EFFENDI, in the *Turkish language*, signifies *master*: and accordingly it is a title very extensively applied; as to the emirs and emirs: to the priests of mosques, to men of learning, and of the law. The grand chancellor of the empire is called *reis-effendi*.

EFFERVESCENCE, is popularly used for a light ebullition, or a brisk intestine motion produced in a liquor by the first action of heat, without any notable separation of its parts.

EFFERVESCENCE, in *Chemistry*, is not applied to all ebullitions or motions produced by fire, but only to those resulting from the mixture of bodies of different natures; which, by their acting on one another, occasion a heat, resembling the ebullition or boiling produced by fire.

The two most common opposites, acids and alkalies, on being mixed, cause a great ebullition or frothing, but no great heat: but the solutions of some metals in aqua fortis cause intense heat, and emit flame. Aromatic oils, mixed with acid mineral spirits, actually kindle and burn with violent explosions: and some vegetable substances, putrefying with moisture, will sometimes heat so as to kindle what lies dry about that part of the heap where the putrefaction happens. Thus heaps of dung will grow hot, and haycocks often kindle into actual fire. Phil. Trans. N° 470. p. 475.

Chauvin defines *effervescence* more scientifically to be a violent expulsion of the air, out of the pores of the particles of one body, by the intrusion of the particles of another body mixed therewith into those pores before possessed by air.

In order for *effervescence* to take place, the particles of the latter body must be supposed consonable, both in bulk and figure, to the pores of the other, so that they may enter and fill the same like wedges; and beside, there must be a strong degree of attraction between the particles of the two bodies, stronger than the attraction or force of cohesion between the particles of either of the bodies alone.

Hence it should seem, that *effervescence* only differs from fermentation in the degree of explosion; which in *effervescences*, occasioned by the greater purity and freedom of the acid and alkali, is greater than in fermentations; but FERMENTATION is now used in a more restricted sense.

Of *effervescences*, some are *hot*, and others *cold*. Of the first kind are those produced by mixture of oil of tartar *per deliquium*, with spirit of vitriol; quicklime, with cold water; all acid *spirits*, with alkaline or earthy bodies; aqua fortis, spirit of vitriol, spirit of nitre, aqua regia, &c. with metallic bodies, marcasites, and minerals; coral, with lemon or orange-juice; marble, with spirit of salt; chalk, crabs eyes, mother of pearl, and all shells, with acids. In all which, the *effervescences* are attended with a more or less intense heat.

The principal bodies in which *effervescences* happen, are, 1. Native vegetable acids, as most juices of trees, shrubs, and plants, that run in the spring; most juices of unripe summer fruits; particular juices, when ripe, as those of oranges, lemons, citrons, tamarinds, sorrel, wood-sorrel, and crabs; fermented vegetables, as the meals when they turn sour, Rhenish and Moselle wine, and tartar; vegetables twice fermented, native and distilled vinegars; the acids of animals, from tartish or acid vegetable aliment, as in the chyle, sour milk, whey, butter-milk, and the whey thereof. 2. The native fossile acids, as the acid of sulphur, alum, or vitriol; or these acids, as they lie concealed in sulphur or vitriol stones, or as thence extracted by a violent fire, or a stronger acid, as in the spirit of nitre, salt, alum, vitriol, or sulphur. 3. True fixed alkalies, made of any vegetable matter by burning; the more volatile alkalies, whether spontaneous, as in garlic, onions, scurvy grass, mustard, &c. produced by putrefaction from animal or vegetable subjects, or procured from the same by distillation and burning. 4. Certain bodies, improperly called alkalies, only on account of their agreeing with genuine alkalies, in fermenting with acids; these are many of the bones, and other earths, bones, chalk, corals, crabs eyes, horns, hoofs, and nails of animals, pearls, shells of fish, &c. stones, and teeth. 5. The seven metals. 6. The semimetals, antimony, bismuth, lapis calaminaris, hæmatites, lime, and the like.

Hence we have four general rules: 1. That the bodies of the first class almost constantly make an *effervescence* with those of the third and fourth, either sooner or later, and with more or less strength, as they are in themselves weaker or stronger: this *effervescence* continues till the point of saturation is obtained, and then ceases; and at that time usually the acrimony both of the one and the other of the substances is softened. 2. The bodies of the first class make an *effervescence* with those of the fifth, though only some with others, and not universally: some do this with more, and others with less strength; and at the end, vitriols are usually produced. 3. The bodies of the first class act in the same manner with those of the sixth. 4. The bodies of the third, fourth, fifth, and sixth classes, being mixed together, are scarce found to make any *effervescence*; hence acids are found to have this effect in particular along with the rest, though here it is limited. The best spirit of vinegar, poured upon oil of tartar *per deliquium*, makes no *effervescence* at first, but it does afterwards, and in doing it, weakens the alkali.

Pure volatile alkali, when freed from its oil, makes an *effervescence* with distilled vinegar; but much more cold than heat arises in the ebullitions of this kind; whereas, the generality of other *effervescences* produce heat in various degrees, from the least sensible warmth up to actual flame. A dram of oil of cloves, mixed with two drams of Glauber's spirit of nitre, raises a thick smoke, and in the midst of it a strong red flame, and the matter is reduced to a dry spungy mass: in this case the *effervescence* is not made with acid and alkali, but with acid, and a very rich oil. There are also two hard and cold bodies,

viz. iron and ſulphur, which being ground together, and made into a paſte with water, make a ſpontaneous *effervescence*, and will even produce actual fire and flame. Boerh. Chem. part ii. p. 340.

Oil of vitriol, and oil of turpentine, mixed together, produce ſuch a vehement heat, that unleſs they be mixed drop by drop, they are apt to burſt forth into a flame, and break the phial.

Generally the ſubſtances, which contain a ſenſible quantity of the inflammable principle, are thoſe which in ſimilar circumſtances produce the greateſt heat in *effervescing* with acids; and of all acids, the nitrous produces the greateſt heat, when it diſſolves theſe bodies.

Powdered coral, mixed with diſtilled vinegar, produces a cold *effervescence*, which has been accounted for hence, that the pores of the coral being very great, it may be eaſily diſſolved in the acid ſpirit, without any great friction or colliſion of the parts, ſuch as would be neceſſary to generate any conſiderable heat.

An *effervescence* may alſo be produced by the mixture of many other cold liquors. See DISSOLUTION.

EFFERVESCENCE, in *Vintage*, a term appropriated by Portzius and others, to ſignify that working of wine, which is by ſome, though improperly, called fermentation, thereby confounding two very different things. Fermentation, according to theſe authors, is nothing elſe but the action and re-action of the internal parts of the acid and alkali of the fluids, by which the ſpirits are ſeparated without precipitation; whereas, they ſay, by *effervescence*, there are no ſpirits ſeparated, ſo that all fermentation is done by means of *effervescence*; but all *effervescence* does not amount to fermentation. Fermentations are properly the mutual ſtrugglings between contrary principles, as between acid and alkali, or the like; but *effervescences* will happen between principles of the ſame kind, provided one be much ſtronger than the other. Thus a ſtronger acid, poured upon a weaker, will raiſe an *effervescence*, but no fermentation. The *effervescence* of wine is not, however, of this kind, but the acid and alkali which are in them muſt raiſe this by their action upon one another, the alkaliſate parts combating with the acid ones, till they have wholly fated them, and then the *effervescence* ceaſeth.

It has been obſerved by many, that wine in the caſks will always *effervesce* more or leſs ſtrongly, at the time of the bloſſoming of the vines. This has been ſuppoſed by the vulgar to be owing to ſomething of ſympathy, or ſuch hidden cauſes; but it is only owing to the heat of that ſeaſon, which ſet the two ſalts at work upon one another. Portzius de Vin. Rhenan.

EFFICACIOUS, EFFECTUAL, in *Theology*. Within theſe 150 years there have been great diſputes on the ſubject of *efficacious* grace. Grace is uſually divided into ſufficient and *efficacious*; though the Janſeniſts hold, that there is no grace ſufficient but what is *efficacious*, i. e. but what effectually determines the will to act.

Efficacious grace is that which enlightens the mind, and touches the heart, in ſuch a manner, as always to produce its effect, however it be oppoſed or reſiſted by the will. See GRACE.

Some divines maintain, that *efficacious* grace is *efficacious* of itſelf. *Efficacious* grace of itſelf, if there be any ſuch thing, is that which produces its effect merely of itſelf, and not in virtue of any conſent of the will. Calvin is the firſt that uſed the term, *gratia efficax per se, grace efficacious of itſelf*.

A late divine holds the *efficacy* of grace in itſelf to conſiſt in this: that *efficacious* grace is always joined with a moral neceſſity of doing the thing it inclines to; and ſufficient grace, joined with a moral impotence of doing it. The Arminian and Popiſh way of conceiving the neceſſity of *efficacious* grace, is, that this grace is never wanting, at leaſt to the righteous, except through their own default; that they always ſtand in need of other inner graces truly and properly ſufficient, in order to draw down this *efficacious* grace; and that theſe do infallibly draw it down, when they are not rejected, though they often remain without effect, becauſe men reſiſt, inſtead of yielding their conſent thereto.

F. Malebranche maintains, that the mutual commerce between ſoul and body, i. e. life, has no other vinculum or principle but the *efficacy* of God's decrees; and that ſecond cauſes have no proper *efficacy*, &c.

EFFICIENT, in *Philoſophy*. An EFFICIENT *cauſe* is that which produces an effect. See CAUSE and EFFECT.

Philoſophers uſually diſtinguiſh four kinds of cauſes in nature; the *efficient*, *final*, *formal*, and *material*. See each under its proper article.

The ſchool-philoſophers are exceedingly divided as to the nature and eſſence of an *efficient cauſe*. Ariſtotle defines it, *id unde, that from which*; or the firſt principle of change and reſt, i. e. of production and converſation.

The *efficient* is called *id unde, that from which*; as the end or final cauſe is that *propter quod, for which*; the exemplar, *ad quid, that to which*; the matter, *ex quo, that out of which*; and the form, *per quod, that by which*.

Others of the ſchoolmen define *efficient* to be *principium per ſe influens in aliud ſive mutatione ſui*. The Ramiſts, after Plato and Cicero, define an *efficient* to be that, *a quo res eſt, from which a thing is*; to which a great author object, that a thing may be alſo from its end, adds, that an *efficient* is that, *a qua res cum conſtitutur reſiſtitur*. Others define *efficient* to be, *quæ per actionem tendit, that which tends by acting*; for to effect, every body knows, is to act: and hence neither a procatarctic, nor an exemplary cauſe, are properly *efficient*, though uſually ranked among them.

Laſtly, others define an *efficient* to be a cauſe, *a qua aliud producatur, from which ſomething is produced*; conſequently, what ariſes from ſuch a cauſe is called an *effect*; and thus God is the *efficient* cauſe of the world, and the world the effect of God: to which definition of an *efficient*, all the former definitions are reducible.

An *efficient cauſe*, then, is either phyſical, as the fire is the *efficient* cauſe of heat; or moral, as an adviſer is the cauſe of a murder; or univerſal, which in various circumſtances produces various effects, as God and the ſun; or particular, as a horſe which produces a horſe; or univocal, which produces an effect like itſelf, as a horſe begets a horſe; or equivocal, according to the old doctrine, as the ſun producing a frog; or natural, which acts not only without precept in oppoſition to artificial, but alſo from within, and according to its own inclination, in oppoſition to violent, as fire acts when it warms; or ſpontaneous, as a dog eating; or voluntary and free.

Others conſider *efficient* cauſes, either as principal, or as inſtrumental; others, either as next or remote, or as mediate or immediate; others, in fine, divide *efficient* cauſes among all the kinds of beings, natural and ſupernatural, ſpiritual and corporeal, ſubſtantial and accidental, vital, and not vital, &c.

But the moſt celebrated diviſion of *efficients* is that into *firſt* and *ſecond*.

A *firſt efficient* cauſe is that between which and the effect there is ſome neceſſary connection: of which kind there is none but God alone.

A *ſecond efficient* cauſe is that from which an effect follows in conſequence of the will or conſtitution of the Creator, and which the Carteſians call an *occaſional cauſe*.

But theſe precautions or occaſional cauſes are, in reality, no cauſes at all, but only antecedent effects. This is eaſily ſhewn: for 1, All action, at leaſt all corporeal action, is continued in motion; but motion can only reſult from the firſt cauſe, it being an allowed principle, that body of itſelf is inert and inactive. The true cauſe of motion, therefore, is a ſpiritual, not a corporeal nature. 2. But neither can a finite ſpiritual nature be the chief cauſe of motion; for there is no neceſſary connection between the will, e. gr. of an angel, and the motion of a body, nor between that of any other being except God. Thus when an angel wills, a ſtone moves, becauſe God has conſtituted ſuch a law between the will of the angel and the motion of the ſtone; and thus we move our hands when we pleaſe; not that the ſoul is the principal cauſe of ſuch motion, but only the occaſional cauſe. See CAUSE.

EFFICIENTS, in *Arithmetic*, the numbers given for an operation of multiplication, called alſo the *factors*. See FACTOR and COEFFICIENT.

The *efficients* are the multiplicand and multiplier.

EFFIGY, EFFIGIES, a portrait, or repreſentation of a perſon to the life. See PORTRAIT.

EFFIGY, is alſo uſed for the print or impreſſion of a coin, repreſenting the prince's head who ſtruck it.

EFFIGY, *to execute or degrade in*, denotes the execution or degradation of a condemned, contumacious criminal, who cannot be apprehended or ſeized.

In France, they hang a picture on a gallows or gibbet, wherein is repreſented the criminal, with the quality or manner of the puniſhment: at the bottom is written the ſentence of condemnation. Such perſons as are ſentenced to death are executed in *effigy*.

EFFLORESCENCE, of *ex, out, and flos, flower*, in *Botany*, denotes the blooming of a flower.

EFFLORESCENCE, in *Chemiſtry*, denotes an operation which certain bodies undergo, when a kind of meal or powder is formed on their ſurfaces; and this may happen either by decompoſition or drying; as to cobalt in the firſt caſe, and to the cryſtals of marine alkali, Glauber's ſalt, alum, &c. in the ſecond.

EFFLORESCENCE, in *Medicine*, a breaking out of humours in the ſkin; as in the meaſles, or the like. See EXANTHEMA.

EFFLUENT *fever*, is sometimes used for an inflammatory fever.

Dr. Morgan proposes to cure such by sweats raised by low cooling drinks.

EFFLUVIUM, a flux, or exhalation of minute particles from any body; or an emanation of subtle corpuscles from a mixed, sensible body, by a kind of motion of transpiration.

Odoriferous bodies, every one knows, are continually emitting subtilantial *effluvia*, by means whereof it is, that they excite in us the sense of smelling. These minute *effluvia* are sometimes perceived by the eye, in form of fumes and vapours.

Some bodies are found to emit *effluvia* for a great number of years, without any considerable loss, either as to bulk or weight; as diverse odorous bodies, the tenuity of whose emanant corpuscles is incredible; not but that the loss they sustain by the continual emission of *effluvia* may be made up to them by the reception of other similar *effluvia* of the same kind of bodies diffused through the air.

It is added, that these *effluvia* are emitted in manner of *radii*, rays, *in orbem*; and the circumference or bound of the activity of the radiation exhibits the same figure as is that of the radiant. This the astronomers sufficiently prove, from the ratio of the refraction of the atmosphere. For the law of the emission of these *effluvia*, see QUALITY.

That *effluvia* may considerably operate upon, and have great effects on bodies within the sphere of their activity, is proved by Mr. Boyle, in an express Treatise on the Subtility of *Effluvia*; where he shews, 1. That the number of corpuscles, emitted by way of *effluvia*, is inconceivably great. 2. That they are of a very penetrating nature. 3. That they move with vast celerity, and in all manner of directions. 4. That there is frequently a very wonderful congruity, or incongruity, in the bulk and shape of these *effluvia*, compared with the pores of the bodies they penetrate into and act upon. 5. That in animal and organical bodies, particularly, these *effluvia* may excite great motions of one part of the frame upon another, and thereby produce very considerable changes in the œconomy? Lastly, that they have sometimes a power of procuring assistance in their operations from the more catholic agents of the universe, such as gravity, light, magnetism, the pressure of the atmosphere, &c.

That *effluvia* are emitted to very great distances, we have a notable proof in odoriferous *effluvia* being in many cases perceived at the distance of many leagues. Again, that the generality of *effluvia* retain the proper colour, smell, taste, and other properties and the effects of the bodies whence they proceeded, and this even after they have passed through the pores of other solid bodies, we have abundant proof. And the same we see confirmed in sympathetic inks and powders, and in the sagacity of blood-hounds, &c.

The wonderful extension of *effluvia*, and the small diminution of the body they issue from, is one of the stringest problems in physics.

The determinate natures of *effluvia*, according to the principal instances we have of them, are reducible to these three heads: 1. That these *effluvia* being, by condensation, or otherwise, reunited, they appear to be of the same nature with the body that emitted them. 2. Their determinate nature may be sometimes discovered by the difference that may be observed in their sensible qualities; forasmuch as those *effluvia* which are endowed with them proceed from the same sort of bodies, and yet those afforded by one kind of bodies being in many cases manifestly different from those which fly off from another; this evident disparity in their exhalation argues, that they retain distinct natures, according to the nature of each body from which they proceed. 3. We may discover this different nature of *effluvia* from their effects upon other bodies than the organs of our senses; considering that the effects which certain bodies produce on others by their *effluvia*, being constant and determinate, and always different from those which other agents produce by their emissions on the same or other subjects, the distinct nature of the corpuscles, emitted on this occasion, may be sufficiently judged of, were it only from this. Boyle on *Effluvia*.

EFFLUVIA, in *Medicine*, are assigned as the cause of various disorders, especially of the contagious kind. Thus, when a considerable quantity of putrid *effluvia* has been admitted into the blood, besides acting thereupon slowly, by way of inquinamentum, or ferment, they seem immediately to affect the nerves, and thereby to bring on some extraordinary disorder of the whole frame. Hence arise spasms, obstructions, palpitation, a high degree of fever, or a languid circulation, chilness, or intense heat, and a variety of contrary symptoms, according to the different affection of the nerves. To putrid *effluvia* is likewise owing the jail-distemper, which is the same with the hospital-fever. See HOSPITAL-*fever*.

Effluvia issuing from corrupted substances chiefly consist of the phlogiston or sulphur principle, which they so readily unite with, and volatilize acids, as appears from the increase and particular change of the former. Now it is proper to remark, that from a simple putrid substance the phlogiston does not arise alone, but combined with the saline parts of the body; for this principle, when single, is perhaps imperceptible to the smell; and, when divested of these salts, is never, so far as is known, pestilential; so that the deleterious particles of rotten substances seem to consist of a certain combination of the sulphurous with the saline principle, which united, not only become the most irritating stimuli to the nerves, but act upon the humours as a putrid ferment in promoting their corruption. Pringle's Obs. on Diseases of the army, p. 186. 385, &c. See AIR *fixed*, and MALIGNANT.

Dr. White, availing himself of the discoveries of Dr. Priestley, has applied *nitrous* AIR in the manner proposed by him, for ascertaining the salubrity of different specimens of air, and the effects of various kinds of *effluvia* upon it. The apparatus employed by him for this purpose consisted of a barometer tube, graduated by inches and decimals, and of such a bore, that an ounce phial of the air to be examined, being thrown into it through a small glass funnel (after it had been filled with water and inverted into a vessel of the same fluid) occupied about 134 decimal parts of an inch, or nearly 13⅓ inches. On adding half an ounce of nitrous air, the mixture generally occupied, at first, about 205 decimal parts; and in half an hour, when the whole diminution may be supposed to have taken place, Dr. White observed the space or number of decimal parts then occupied by the two airs; and substracting it from 205, considered the remainder as the number indicating the state of purity in the particular air he had occasion to examine. When he mixed the air in his garden with the nitrous air in the above mentioned proportion, the space occupied by the mixture in half an hour was 145; and this substracted from 205, gives 60 for the state of the common atmospherical air in that place, and at that time. But had he used the same quantity of perfectly noxious air instead of the air in the garden, there would have been no diminution, and the mixture would have stood at 205, so that 0 would express the condition of that particular air; and therefore he marked the extent of his scale from 0, indicating the most noxious or mortal air to 60° or 62°, which was found to be the mean state of the atmosphere in more than 200 experiments. With this apparatus Dr. White found the difference between the air in the city of York and that of the country, not far from the city walls, to be 3°, the former being 59° and the latter 62°. The air of his bed, on entering it at night, was 62°, but reduced by the next morning to 58°, the bed-curtains being open, and the room large and airy. By breathing the same air as long as he could without inconvenience, he reduced it from 62° to 40°. The air in an eight-ounce phial, which had contained a small piece of fresh veal forty-eight hours, was reduced from 63° to 10°, and yet the flesh was not putrid. Two ounces of black mud, taken from a stinking morass at York, being put into an eight-ounce phial of air, reduced it in twelve hours from about 60° or 62° to 34° or 36°. When this mud became perfectly dry, so as to be pulverized, the diminution it occasioned was only from 62° to 60°: but when this powder was again reduced to mud, by the addition of a little water, and enclosed in a phial as before, it affected the air so as to reduce the diminution from 62° to 49°: and on standing longer, from 62° to 29°. When more water was added, so as to swim at some height above the powder, which had subsided, the air again, tried by the test, never produced a greater reduction of the diminution than from 62° to 50°. These experiments confirm the observations of Dr. John Pringle and other medical writers, who have remarked, that the diseases peculiar to low marshy situations seldom begin to appear till the water is so far evaporated as to leave a black and slimy mud; that they cease when the bogs and marshy ground have been drained and become perfectly dry; and that, on the other hand, the danger arising from marshes and bogs is, in a great measure, obviated, on their being laid wholly under water; or in the words of this ingenious writer, the putrid fermentation is either prevented by too much moisture, or the *effluvia* are absorbed in passing through the superincumbent bed of water. Phil. Trans. vol. lxviii. part i. art. 13.

The earth sends forth *effluvia* and steams in great abundance, and many things attributed to other agents, are really

really performed by them. Dr. Woodward has very justly attributed great effects to them on fossils of many kinds; and it is possible many more of the present appearances of subterranean bodies may be owing to them than are at present imagined. The figures and delineations on stones, in form of trees and shrubs, have often their origin from these *effluvia*, getting into the cracks of them: and it is possible, that the stalactitæ, which we find on the roofs of caverns, may be in great part also formed by their means. Phil. Trans. N° 169. p. 920.

As for the *effluvia* proceeding from stagnant waters, mines, &c. see AIR *Mephitic* and DAMP.

EFFLUXION, a flowing out, from *ex, out of*, and *fluere, to flow*.

EFFRACTURA, a word used by Ambrose Parey for a peculiar species of fracture of the skull, in which the bone is at once broken and depressed.

EFFRONTES, in *Church History*, a sect of heretics, in 1534, who scraped their forehead with a knife till it bled, and then poured oil into the wound. This ceremony served them instead of baptism. See BAPTISM.

They are likewise said to have denied the divinity of the Holy Spirit.

EFFUSION, the pouring out of any liquid thing with some degree of force.

In the ancient heathen sacrifices there were divers *effusions* of wine, and other liquors, called *libations*.

EFFUSION, or FUSION, in *Astronomy*, denotes that part of the sign Aquarius, represented on celestial globes and planispheres, by the water issuing out of the urn of the Water-bearer. See AQUARIUS.

EFFUSION *of blood*, *effusio sanguinis*, in our *Old Writers*, is used for the mulct, fine, or penalty, imposed for the shedding of blood. This the king used frequently to grant to lords of manors. Among others it was granted to the Abbot of Glastonbury.

EFT, or EFF, in *Zoology*, the name of a creature very common in all parts of England, and called also *newt*, and the *swift*, and by others the *common lizard*, *lacertus vulgaris*.

The beak or snout of this creature is oval and obtuse; its back of a rusty iron-colour; its feet have each five toes, and are armed with very sharp though small claws. That toe which is in the place of the fore-finger with us is the longest of all; and that which answers to our thumb is placed lower. Ray's Syn. Quad. p. 264.

We have several species of this animal with us. 1. The common land *eft*, with the black spotted belly. 2. The snake-like *eft*, which is frequent in our heaths. 3. The small brown land *eft*. This is very scarce. 4. The yellow scaly land *eft*, described by Plot in his History of Staffordshire. And, 5. The brown and black spotted water *eft*. Plott's Staff. p. 252.

The land *eft*, or as the naturalists often call it, the land *salamander*, has something very remarkable in its outer coat. Its skin often appears dry, like that of the lizard kind, but often also it appears wetted, and as if covered with a fine shining varnish: the change from one to the other of these states is usually performed in an instant, and it frequently becomes immediately wet all over on touching it. It also consists, under the skin, a sort of milky liquor, which spurts out to a distance on pressing the body of the animal.

The passages for this milk are a vast number of pores or holes, many of which are plainly visible to the naked eye; and very probably the first-mentioned liquor, which covers the skin in manner of a varnish, may be the same with this, its white colour not being distinguishable when it is spread so thin over the surface of the animal. This milk resembles very much the milky juice which the tithymals, and many other of the succulent plants afford on being cut or broken. It is of an insupportably acrid and styptic taste; and though the tongue receives no injury from touching it, yet the sensation is so violent, that one is apt to imagine there must be a wound made in it. This animal, when bruised, yields also a very disagreeable smell.

It has generally been supposed, that this animal is of a poisonous nature; and the famous salamander of the old writers seems to be of the same genus, if not the same animal. Mr. Maupertuis, determined to inform the world of the truth in regard to these remarkable particulars, caused a large number of these animals to be brought to him, which the country people, who had caught them about the bottom of old walls, brought to him with as much caution as if they had been vipers.

From his trials, it appeared very evident, that the stories of this creature's being poisonous, are as idle and groundless as those of its living in the fire.

One thing remarkable this gentleman observed in his dissections of the animal, which was, that he found in several of the females, at once clusters of eggs, and living young ones. The eggs formed clusters resembling those of the ovaries of birds, and the young ones were contained in two tubes, or long pipes, the coats of which were perfectly transparent, and the young ones were easily distinguished through them; and there were counted in one female fifty-four of these, all living and vigorous. Mem. Acad. Par. 1727.

The water *eft* affords an excellent opportunity of seeing the circulation of the blood by means of the microscope, particularly of the solar one. By this apparatus the vessels are seen beautifully delineated on the skin; and the tide of blood, in the large ones, is equal to that of the stream of water which is shewn in hydrostatical experiments thrown out of a vessel by condensed air. In either of these cases, you can see no appearance of separate drops of globules, but the whole forms one continued body. In the lesser vessels the globules are seen passing along very swiftly, yet evidently separate one from another.

It is remarkable, that in the tail of this animal there seem a greater number of vessels than are immediately necessary to the circulation of the blood; for, when thus examined, there will be often seen two parallel vessels, in one of which only the circulation is performed, and this successively in one and the other of the vessels, the tide often leaving the one wholly empty, which had just before been full and circulating in the other. Phil. Trans. N° 460. p. 728.

EFT-*stones*, in the *Materia Medica* of the American Indians, a name given to certain stones, said to be found in the stomach of a certain species of water newt, or *eft*, in the manner of the bezoars in other animals. The writers of Brasil, Cuba, and Mexico, abound with this species of *eft*; but it does not seem well attested, that this sort of stone was ever found in any of them by those who have dissected numbers of them, on purpose to search for it. We have in Europe swallow-stones, and other such things, whose names, and their fabulous histories, would import their being produced in animals. As many swallows have been destroyed in England in looking for these stones, as newts in Mexico in looking for those; and by the appearance of the American as well as the European stones, they both seem to be dug out of the earth, and to have been once the teeth or other parts of fishes. Redi, Experim.

The virtues of the *eft-stone* of Mexico are celebrated by Ximenes, and all others who have been upon the spot. It is said to be a certain remedy for the gravel, and all other nephritic complaints, and even to break and dissolve the stone when already concreted in the bladder. But this account of its virtues seems as improbable as that of its origin. Redi tried these and many other stones of famous character among writers, and found no effect in any of them. These *eft-stones* never produced any visible effect in his trials, in nephritic complaints, nor the eagle stone in women's labour, nor the stones swallowed by Caymans in quartans, though Menardes looks on these last as infallible in this case.

EGERMINATE, of *ex, out*, and *germen, bud*, in *Botany*, signifies to bud or spring out.

EGESTION, from *egero, I cast out*, in *Medicine*, the same with dejection.

EGG, in *Natural History*, a part formed in the females of certain animals; which, under a shell or cortex, includes an embryo, or fœtus of the same species; the parts whereof are afterwards displayed and dilated, either by incubation, or by the accession of a nutritious juice.

The species of animals that lay *eggs* are particularly denominated *oviparous*; and the part wherein the *egg* is formed, the *ovary*.

Of the various kinds of *eggs*, those of hens or pullets being the most usual, and which have been the most observed, we shall say something of the structure thereof, and the generation of the chick therein.

The exterior part, then, of a hen's *egg* is the shell, a white, thin, friable cortex, including all the other parts, and defending them from injuries. The matter of this shell is a fine, absorbent earth, soluble in acids, and calcareous or convertible into quicklime. See *Animal* EARTH.

Eggs with double shells are no unusual phenomenon. Harvey is very diffuse on the rationale of these appearances in his treatise De Generat. Animal.

Immediately under the shell lies the membrana communis, which lines the whole cavity of the shell, adhering pretty closely to it, except at the bigger end, where a little cavity is left between them, containing a small quantity of air, which with age grows bigger. Under this membrane are contained two albumina, or whites, each wrapped up in its own membrane. In the middle of the inner white, is the vitellus, or yolk, enclosed likewise in its separate involucrum or cover. The outer

albumen is oblong or oval, accommodated to the figure of the ſhell: the inner is ſpherical, and of a more craſs or viſcid ſubſtance, and the yolk is of the ſame figure.

The albumen is miſcible with water; and when expoſed to a gentle heat, as that of a healthy man's body, it grows continually more and more liquid, till at length loſing all its conſiſtence, it diſſolves into a liquor reſembling urine; and at the ſame time it waſtes ſenſibly, and at laſt leaves nothing but a thin pellicle reſembling paper. It is, in reality, a matter entirely of the nature of animal jellies, but of that kind which is coagulable by heat: for the albumen, if applied to a degree of heat ſomething greater, inſpiſſates, and hardens into a whitiſh, concrete, flaky ſubſtance, with the loſs of ſome of its finer fluid part, which eſcapes in form of a fume.

In effect, if an *egg* be laid on coals not the moſt intenſely hot, the ſame finer fluid will be found ſenſibly to tranſude the pores of the ſhell. Add, that if ſpirit of wine be poured on the freſh albumen of a new-laid *egg*, a coagulation is immediately produced as if by fire; and this the more perfectly, as the ſpirit and the albumen are more intimately mixed. By this means, the white of an *egg* is defended from all putrefaction.

Diſtilling the albumen by a retort in a ſand heat till it be brought to a dryneſs, it yields an incredible quantity of water, which has moſt of the properties of the whole maſs.

The white of an *egg* makes an extraordinary menſtruum. Being boiled hard in the ſhell, and afterwards ſuſpended in the air by a thread, it reſolves and drops down into an inſipid ſcentleſs liquor, which appears to be that anomalous unaccountable menſtruum ſo much uſed by Paracelſus; and will, though it contain nothing ſharp, oleaginous, or ſaponaceous, make a thorough ſolution of myrrh, which is more than either water, oil, ſpirits, or even fire itſelf, can effect. Boerhaave, New Meth. Chem. part ii. p. 358, ſeq. See MYRRH.

The origination of the albumen is ſomewhat obſcure. It is matter of common obſervation, that *eggs*, while in the ovaries of their birds, e. gr. of hens, conſiſt only of a yolk, without any albumen; and in *eggs*, when boiled, it is apparent, there is only a contiguity, but no connection between the two parts, ſince they are eaſily ſeparated, without a rupture of any thing, except in the places where the chalazæ are found. The reſult of the lateſt obſervations on this ſubject is, that the vitellus being deſcended into the ovary, the cavity of the ovary diſtils the matter of the albumen, and glues, or annexes it to the ſurface of the yolk. Harv. de Generat. Anim. exerc. xiv. p. 57. Bellin. de Mot. Cord. p. 40. Burggr. Lex. Med in voc.

The yolk of the *egg* is alſo compoſed of a gelatinous matter like the white, which coagulates and hardens with heat, and contains a conſiderable quantity of mild fat oil, that may be ſeparated from it by expreſſion.

The albumen is the nutritious juice, whereby the *egg* is diſtended and nouriſhed till it becomes big; and the yolk ſerves it for food after it is well grown, and partly alſo after it is hatched; for a good part of the yolk remains after excluſion, being received into the chicken's belly, as a ſtore-houſe, and conveyed thence by the appendicula, or ductus inteſtinalis, as by a funnel, into the guts, ſerving inſtead of milk.

At each end of the *egg* are the chalazæ, which are, as it were, the poles of this microcoſm: theſe are white, denſe bodies, conſiſting each of three little globules like hail joined together; by theſe, not only the ſeveral membranes are connected, or knit together, by which means the ſeveral liquors are kept in their proper place and poſition to each other, but they ſerve alſo to keep one and the ſame part of the yolk uppermoſt, let the *egg* be turned which way it will.

About the middle, between the chalazæ, on the ſide of the yolk, and in the membrane thereof, is a little veſica or bladder, not unlike a vetch, or lentil, called the CICATRICULA, and by ſome the *eye*, of the *egg*. In this veſicle is contained an humour, in, and of which the chick is generated.

All theſe parts of a pullet's *egg* are found in all other *eggs*, to which the definition of an *egg* properly and ſtrictly agrees: ſuch *egg* being that, of a part whereof the animal is formed, the reſt ſerving for its food. Accordingly, the firſt ſeed, or ſtamen of the chick, is in the cicatricula.

EGGS, in diet, ſerve for an agreeable and nouriſhing aliment; but it is neceſſary, that they ſhould be freſh, and moderately coagulated by heat. If, upon holding them to a candle, they appear of a turbid colour, they are uſually reckoned ſtale; or if, upon preſenting them to the fire, they exhale a moiſture, they are freſh. The yolk is uſed in many medicinal preparations, as emulſions, &c.

EGGS, *Albumina*, or *whites of*, are of ſome uſe in medicine, though rather externally, in the preparation of collyriums for the eyes, and *anucellamata*, on account of their cooling, agglutinating, and aſtringent qualities, than internally.

Albumina are uſed for burns, and in ſome mixtures with bole armenic, &c. for conſolidating freſh wounds, and under bandages, and compreſſes to prevent the exfoliation of bones after reduction. A late writer recommends them as a ſecret in the jaundice. Juncк. Conſp. tab. xiii. p. 379. Quinc. Diſpenſ. part. ii. p. 204. Ephem. Germ. dec. 3. an. 2 obſ. 35. p. 43.

Beſides medical, the whites of *eggs* have alſo their chemical uſes, e. gr. for the clarifying of liquors; to which purpoſe, being mixed, and incorporated with the liquors to be clarified, and the whole afterwards boiled, the whites of *eggs* are by this means brought together, and hardened, and thus carry off the groſs parts of the liquor along with them. They likewiſe form a very white and ſhining varniſh, which is applied to ſeveral kinds of work, and particularly to pictures.

EGG-*ſhell white*, in *Painting*, is ſometimes uſed in water-colours, and preferred to ſtake or the Trop-white: it is prepared by peeling off the inner ſkins, and levigating the ſhell to a proper fineneſs, and waſhing over the powder.

EGG, what is termed *centeninum ovum*, among *Naturaliſts*, denotes a ſort of hen's *egg*, much ſmaller than ordinary, vulgarly called a *cock's egg*; from which it has been fabuloully held, that the cockatrice or baſiliſk was produced. Brown. Vulg. Err. lib. iii. cap. 7.

The name is taken from an opinion, that theſe are the laſt *eggs* which hens lay, having laid a hundred before; whence *centeninum*, q. d. the hundredth *egg*.

Theſe *eggs* have no yolks, but in other reſpects are like common *eggs*, having the albumen, chalazæ, membranes, &c. in common with others.

In the place of the yolk is found a body reſembling a little ſerpent, coiled up, which doubtleſs gave riſe to the tradition of the baſiliſk's origin from hence.

Their formation is probably aſcribed by Harvey to this, that the yolks in the vitellary of the hen are exhauſted before the albumina. Harvey de Generat. Animal Exerc. 12.

M. La Peyronie has carried the hiſtory of the *ova centenina* to a greater length, as well as certainty: a hen was brought to him, which, for a conſiderable time, laid no other *eggs*. The ſame hen was alſo obſerved to crow like a cock, and to render by the cloaca a thin yellow matter, much like the yolk of an *egg* diluted in water. Upon opening her, ſhe was found hydropical; a bladder as big as the firſt, full of water, was found contiguous to the oviduct, which it preſſed and crowded in ſuch manner, as not to leave the cavity thereof above five lines in diameter; ſo that a common *egg*, ſuch as it is when it falls from the ovary into the tube, could not paſs without burſting, by which the yolk was let out, and diſcharged another way. Mem. Acad. Scienc. an. 1710. p. 730.

EGGS, *preſervation of*. Mr. de Reaumur, of the Paris academy, thinking nothing that could be a public benefit beneath the cognizance of a philoſopher, beſtowed conſiderable pains on finding a method of preſerving *eggs* for a long time, and ſucceeded at length ſo far in it, as to be able to produce *eggs* of months, nay years old, which taſted as freſh and well as if they had been laid but the day before. The *egg* always is quite full, when it is firſt laid by the hen, but from that time it gradually becomes leſs and leſs to its decay; and however compact and cloſe its ſhell may appear, it is nevertheleſs perforated with a multitude of ſmall holes, though too minute for the diſcernment of our eyes. The effect of theſe, however, is evident, by the daily decreaſe of matter within the *egg*, from the time of its being laid, a fluid matter is continually perſpiring through theſe perforations of the ſhell, which occaſions the decay; and this is carried on in a much quicker manner in hot weather than in cold. To preſerve the *egg* freſh, there needs no more to be done than to preſerve it full, and ſtop its tranſpiration; and the plain and rational method of doing this, is by ſtopping up theſe pores through which the matter tranſpires, with a matter which is not ſoluble in watery fluids, and therefore cannot be waſhed away by the matter perſpired by the *egg*; and on this principle, all kinds of varniſh, prepared with ſpirit of wine, will preſerve *eggs* freſh for a long time, if they are carefully rubbed all over the ſhell. This might ſeem to moſt people a very common and cheap ſubſtance for this purpoſe; but the misfortune is, that in country places, where it ſhould be put in practice, no ſuch thing is to be had: and the poorer ſort of country people are not eaſily brought into the uſe of any thing to which they are not accuſtomed.

To

To obviate the difficulty arising from this, Mr. Reaumur thought of ſubſtituting in the place of varniſh ſome other ſubſtance more common; and ſoon found, that another ſubſtance, which is very cheap, and every where to be had, would very well ſupply the office of varniſh; for experiments proved, that any hard fat would have the ſame effect. The beſt of all fat for this purpoſe, is ſuppoſed to be a mixture of that of mutton and of beef; theſe ſhould be melted together over the fire, and ſtrained through a linen cloth into an earthen pan; and when thoroughly melted, an *egg* is to be dipped into it, and immediately taken out again; and it is then in a ſtate to keep perfectly freſh more than a twelvemonth. Memoirs Acad. Scienc. Par. 1735.

The only difficulty attending this method is, that the *eggs* cannot be ſo eaſily plunged into the fat, as that all their ſurfaces ſhall be covered by it; for if they are held in a pair of pincers, the parts of the *egg* where the pincers touch will be bare; but the *eggs* may be ſuſpended by a loop at the end of a thread, and by that means plunged in; and the thread being then cutted over with the fat, as well as the ſurface of the *egg*, will preſerve that part which it covers as well as the coat of fat will the reſt. The great care is to uſe this means while the *eggs* are *perfectly freſh*; it ought indeed be done on the very day when they are laid; for if the evaporation is begun, and the empty ſpace once made, there is room for a fermentation, which never terminates but in the deſtruction of the *egg*.

There is one advantage in this uſe of fat rather than varniſh, which is, that the *eggs* rubbed over with it boil as quick as if nothing had been done to them, the fat melting off as ſoon as they touch the hot water; whereas the varniſh, not being ſoluble even in hot water, only becomes moiſtened by it, and ſtill hanging about the *egg*, prevents the tranſpiration of juices, neceſſary to bring the *egg* to that ſtate in which it is to be eat. When the *egg* which has been preſerved by fat, is taken out of the water, there remains very little fattineſs upon it, and what there does is eaſily wiped off with a napkin, the *egg* is as nicely freſh as if laid but the day before, and no palate can diſtinguiſh the leaſt difference.

The method of preſerving them by means of fat, is greatly preferable alſo to that by varniſh, when they are intended for putting under a hen to be hatched; as the fat eaſily melts away by the heat, while the varniſh remains and impedes the hatching. By this means the *eggs* of foreign fowl might be ſent over and hatched here, whereby many beautiful and valuable birds may be naturalized among us.

At Tonquin they are ſaid to keep *eggs* entire for three years, by covering them up in a paſte made of aſhes and brine.

EGGS, *ant.* See ANT.

EGGS *of fiſh*. After the congreſs with the male, the female fly is ſeldom ſo much as twenty four hours before ſhe begins to depoſit her *eggs* on ſome ſubſtance proper to give nouriſhment to the worms that are to be produced from them.

The *eggs* are but a little time in hatching; and the growth, and all the changes of the animal, take up but a little time. The creature is found to make its way out of the upper part of the *egg*; and it is not more than three weeks from the laying of the *egg* that is taken up, before the creature is ſeen in the form of a perfect fly, if a female, and ready to depoſit hers.

Among the butterfly claſs, the female has but one congreſs with the male, by which the *eggs* are fecundated, and immediately after it begins to depoſit her *eggs*, and continues ſo doing, without interruption, till ſhe has finiſhed; but it is much otherwiſe with the two-winged flies: for they, after having laid one ſet of *eggs*, have repeated congreſſes with the male for ſeveral days; and, after every one of theſe, lay a new ſet.

The female of the butterfly claſs does not depoſit her *eggs* on any plant at random, on which ſhe happened to be placed when the male coupled with her, but ſearches out ſuch a ſpecies of plant for leaving them on, as is what ſhe loved when in the caterpillar ſtate, and what the young caterpillars to be hatched from them will be able to feed on, that they may find food ready for them at the moment of their birth. She does not ſcatter them about irregularly, and without order, but ſhe diſpoſes them with perfect ſymmetry; and faſtens them one to another, not by their own glutinous nature, but by a viſcid liquor, which ſhe ſeparates for that purpoſe. In many ſpecies alſo, where the hinder part of the body of the female is covered with long hairs, ſhe by degrees throws off all thoſe hairs, and with them makes a neſt for the *eggs* ſhe is laying, where they are kept very ſoft and ſafely, till the time of their hatching. This, indeed, is the whole buſineſs of her life; and when the *eggs* are all laid, ſhe dies. Memoirs Acad. Scienc. Par. 1736.

The *eggs* of butterflies are of very different ſizes, according to the ſpecies; they are alſo of many different figures, ſome are ſpheric, others ſegments of ſpheres, others conic, in different forms and degrees: nor is this all, their ſurfaces are very different alſo in the different kinds. Some are elegantly wrought, as it were; ſome dented; and others more deeply notched at the ſides; and others channelled or furrowed all over. In ſhort, the moſt ingenious artiſt could ſcarce contrive ſo many various ornaments as there are on theſe *eggs*, all which alſo are inviſible to the naked eye, being diſcoverable no way but by the microſcope.

The *eggs* of the different ſpecies of the two-winged flies are alſo of very different figures.

There are ſome ſpecies which faſten their *eggs* to the ſides of veſſels of water; theſe all lay oblong *eggs*: ſome of them, however, are perfectly ſmooth in all parts; and thoſe of other ſpecies ſmooth only on their inner ſurface, and ridged longitudinally on the other. What is alſo the more remarkable in theſe, is, that they all have a fine thin ſtake running down all along the two ſides, diametrically oppoſite; and theſe two bands ſurrounding the whole *egg* in this manner, have much the appearance of a caſe, and give the *egg* the appearance of being incloſed in a paper frame. It is probable, that the uſe of this frame is to hold the body of the *egg* the better ſaſtened againſt the veſſel; and probably thoſe *eggs* which have it not, are depoſited from the body of the female fly with a viſcous matter about them, in ſufficient quantity to faſten them on without this aſſiſtance.

There are ſome *eggs* of the fly kingdom which muſt neceſſarily be held faſt to ſome other body, in order for the worm to be able to make his efforts towards the opening of them, without carrying them away; and ſome of the ſpecies require much more ſtrong attachments of this kind than others.

On the ſtalks of the common meadow graſſes there are alſo frequently found the *eggs* of flies depoſited in great numbers. On other ſtalks of graſs, one may often ſee alſo yellow ſpots and blotches, which may naturally enough paſs with an incurious obſerver for maladies of the plants; but, when examined with the microſcope, they appear to be, in reality, cluſters of *eggs*, and amaſſed in different numbers: ſometimes alſo they are formed perfect and whole, and at others with their ends eaten. Theſe laſt are ſuch *eggs* from which the worms have made their way. Theſe worms are white, and have a variable head, armed with two hooks, but their changes are not known. Reaumur, Hiſt. Inſect. vol. iv. p. 376—383.

EGGS *of gnats*. There are few creatures in the winged kingdom more prolific than the gnat. Its whole ſeries of changes, from the *egg* to the perfect animal, is uſually accompliſhed in three weeks or a month; and there are commonly ſeven generations of them in a year, in each of which every female is the parent of two or three hundred young ones, if all the *eggs* come to proper maturity. Theſe *eggs* are arranged by the animal in the form of a ſmall boat, and each ſeparate *egg* is of the ſhape of a ninepin. The thicker ends of theſe are placed downwards; they are all firmly joined to one another by their middles; and their narrower, or pointed parts, ſtand upwards, and make the upper ſurface of the boat of *eggs*, as it were, rough or prickly.

When theſe *eggs* are examined ſingly by the microſcope, they appear not exactly of the ninepin ſhape; the larger end is rounded, and terminated by a ſhort neck, the end of which is bordered with a ridge, which makes a kind of mouth. The neck of each of theſe is ſunk within the water on which the boat ſwims: for it is neceſſary that it ſhould keep on the ſurface, ſince if wholly ſubmerged, the worms could never be hatched.

It is only in the *morning* hours that the gnats are to be found laying their *eggs*: and then they will frequently be found about the ſurfaces of ſuch waters as are in a proper condition to give ſupport to their young. The female gnat here places herſelf on a ſmall ſtick, the fragment of a leaf, or any other ſuch matter, uſually near the water's edge, and places her body in ſuch a manner, that the laſt ring but one touches the ſurface of the water; the laſt ring of all, whereto there is the paſſage for the *eggs*, is turned upward, and every *egg* is thruſt out vertically; and the creature, when it is almoſt diſengaged, applies it againſt the ſides of the already formed cluſter, to which it readily adheres, by means of a mucilaginous ſticking matter with which it is naturally covered, like the *eggs* of many other inſects. The greateſt difficulty to the creature, is the placing of the firſt laid *eggs* in a proper poſition to receive the reſt, and ſuſtain themſelves and them in a proper direction; theſe ſhe, with great precaution, places exactly, by means of her hinder leg; and when a ſufficient number of them are

thus

thus arranged together, the reſt is eaſy, becauſe they ſerve as a ſupport to all the following. Reaumur, vol. iv. 615, &c.

An EGG, improperly ſo called, is that, of the whole whereof the animal is formed: ſuch as are the *eggs* of flies, butterflies, &c. which Ariſtotle calls *vermiculi*.

The two have this farther difference, that whereas the former, after they are excluded from the female, need no external nutriment, nor any thing but warmth and incubation, to bring the *fœtus* to perfection: the latter, after they are fallen out of the ovary into the uterus, require the nutritious juices of the uterus to diſtend and enlarge them; whence they remain much longer in the uterus than the other.

The principal differences among *eggs*, properly ſo called, are, that ſome are *perfect*, i. e. have all the parts above deſcribed, white in the ovary or uterus; and others, *imperfect*, as not having all thoſe parts till after they are excreted or laid; ſuch are the *eggs* of fiſh, which, after they are brought forth, aſſume an albumen to themſelves in the water.

Another difference is, that ſome are *fecundated*, and others not: the firſt are thoſe which contain a ſperm, injected by coition of the male, to diſpoſe them for conception; the reſt, not impregnated with this ſperm, never breed young by incubation, but always putrefy.

An *egg* fecundified contains the rudiments of the chick, before the hen has ſat upon it. By the microſcope, we ſee, in the middle of the cicatricula, the plain carina of the chick, ſwimming in the ligament or humour: it conſiſts of fine white bones or threads, which the warmth of future incubation enlarges, by rarefying and liquefying the matter firſt of the albumen, and then of the vitellus, and preſſing them into the veſſels of the cicatricula, for a farther preparation, digeſtion, aſſimilation, and accretion, till the chick, too big for its coverture, breaks the ſhell, and is delivered.

Malpighi has made very curious obſervations with the microſcope, of all the changes that happen in the *eggs*, every half hour of incubation; and the learned Dr. Monro has given a ſummary of ſeveral obſervations of this kind. Med. Eſſ. Edinb. vol. ii. art. 10.

Voſſius, and diverſe other authors, are very ſollicitous about ſetling the queſtion, which was formed firſt, the *egg* or the pullet. De Idolol. lib. iii. cap. 78.

In Egypt, they hatch their *eggs* by the heat of a furnace, or oven, and frequently have ſeven or eight thouſand chickens come forth at a time. An account of the method hereof we have in the Philoſophical Tranſactions. See HATCHING.

It was anciently thought, that none but birds and fiſhes, with ſome other animals, were produced *ab ovo, from eggs*; but the generality of the moderns incline to think, that all animals, even man himſelf, is generated the ſame way. Harvey, de Graaf, Kerchringius, and ſeveral other great anatomiſts, have ſo ſtrenuouſly aſſerted this opinion, that it now generally obtains.

In the teſtes of women, are found little veſicles, about the ſize of green peas, which are accounted as *eggs*; for which reaſon theſe parts, which the ancients called *teſticles*, the moderns call *ovaries*. Theſe *eggs*, fecundified by the moſt volatile and ſpirituous part of the ſeed of the male, are detached from the ovary, and fall down the Falloppian tubes into the uterus, where they grow and increaſe.

This ſyſtem is countenanced and confirmed by abundance of obſervations and experiments. M. de St. Maurice, upon opening a woman at Paris, in 1682, found a fœtus perfectly formed in the teſticle.

Among the ancients, the *egg* was the ſymbol of the world; it being a tradition among them, that the world was made of an *egg*; whence *eggs* became of ſingular importance in the ſacrifice of Cybele, the mother of the Gods. Some of their deities, they ſay, were likewiſe produced from *eggs*.

Berger, in his treatiſe de Natura Humana, lib. ii. cap. 5. p. 401, makes no ſcruple to give it as his opinion, that the only difference between animals, called *oviparous*, and thoſe denominated *viviparous*, conſiſts in this: that the former caſt their *eggs* out of the body, and lay them in neſts; and that their *eggs* contain all the nouriſhment requiſite for the fruit, or fœtus; whereas, in the latter, the *eggs* are only laid from the ovary into the uterus; that they have but little juice; and that the mother furniſhes the reſt.

There is not ſo much as a plant, whoſe generation, according to the ſentiment of Empedocles, and ſince him of Malpighi, Rallius, Fabric. de Aquapendente, Grew, and others, is not effected by the means of *eggs*.

EGG, *wind*. See WIND-*Egg*.

EGG, *ſea, Echinus Marinus*. See ECHINODERMA.

EGG, *earth*, is a name which ſome authors give to a kind of bezoard, found in the ſtomach of the cow kind.

EGG, in *Architecture*, an ornament of an oval form, cut in the echinus, or quarter-round of the Ionic and Compoſite capitale. The profile, or contour of the [illegible] is enriched with *eggs* and anchors, alternately. See *Tab. Archit. fig.* 10.

EGG, *philoſophical*, in *Chymiſtry*. See PHILOSOPHICAL.

EGILOS, in *Botany*, a name given by Serapion's interpreters, to the plant which that author and Avicenna call alachuir. Their deſcriptions of the plant abundantly prove, that it is the ſame with the achillea of the Greek writers; and this word *egilos* ſeems only a barbarous name for that plant, formed on a miſ-ſpelling of the achillea.

EGITILLIA, a name by which ſome have called the ſtone ÆGYTILLA.

EGLANTINE, or *ſweet briar*, a ſpecies of ROSE.

EGLECOPALA, the name of a ſpecies of ſtony bluiſh MARLE.

EGOITOS, a term uſed by Van Helmont, to expreſs the light of underſtanding, by which we reflect and reaſon within ourſelves.

EGRA *ſal, Egranum ſal*, a name given by Hoffman, and other writers, to a purging ſalt, extracted from the waters of *Egra* by evaporation. The waters of this place are in great eſteem for many diſeaſes; and are, by Hoffman himſelf, in ſome reſpects, preferred to the Pyrmont, as containing leſs ochre and calcareous earth. The ſalt is wholly of the nature of Glauber's ſalt, as is alſo that of many other ſprings thereabout, and even in our own country.

EGRA *water, Egrana aqua*, the water of a medicinal ſpring, near that place in the German dominions. It is famous for cleanſing the viſcera, obſtructed with viſcid matter, and is found of great ſervice in all hypochondriacal caſes, and all diſeaſes ariſing from infarctions of the viſcera; it gently purges by ſtool, and affords a ſalt, known among the German writers by the name of *Egranum ſal*.

EGUILETTE, in the *Manege*. See YERKING.

EGUISCE, ſee AIGUISCE.

EGYPTIANS, popularly *Gypſies*, in our ſtatutes, a kind of impoſtors and jugglers, who diſguiſe themſelves in uncouth habits, ſmearing their faces and bodies, and framing to themſelves a canting language, wander up and down, and under pretence of telling fortunes, curing diſeaſes, &c. abuſe the common people, trick them of their money, and ſteal all that they can come at. There are ſeveral ſtatutes made againſt them.

Egyptians coming into England are to depart the realm in fifteen days, or be impriſoned, by 22 Hen. VIII. cap. 10. And by 1 and 2 P. & M. cap. 4. any perſon importing them into this kingdom, ſhall forfeit forty pounds; and if they remain here above one month, or if any perſon, fourteen years old, conſort with them, they are guilty of felony, without benefit of clergy. 5 Eliz. cap. 20. And we are informed by Sir M. Hale, that at one Suffolk aſſizes, no leſs than thirteen *Gypſies* were executed upon theſe ſtatutes, a few years before the Reformation. See alſo 39 Eliz. cap. 4. § 2. 17 Geo. II. cap. 5. § 2.

The origin of this tribe of vagabonds is ſomewhat obſcure; at leaſt, the reaſon of the denomination is ſo. It is certain, the ancient *Egyptians* had the character of great cheats, and were famous for the ſubtilty of their impoſtures; whence the name might afterwards paſs proverbially into other languages, as it is pretty certain it did into the Greek and Latin; or elſe, the ancient *Egyptians*, being much verſed in aſtronomy, which in thoſe days was little elſe but aſtrology, the name was on that ſcore aſſumed by theſe tellers of good fortune.

Be this as it will, there is ſcarce any country of Europe but has its *Egyptiani*, though not all of them under that denomination: the Latins call them *Ægyptii*; the Italians, *Cingani* and *Cingari*; the Germans, *Zigeuner*; the French, *Bohemiens*; others, *Saraceni*; and others, *Tartari*, &c.

Munſter, Geogr. lib. iii. cap. 5. relates, that they made their firſt appearance in Germany, in 1417, exceedingly tawny and ſun-burnt, and in pitiful array, though they affected quality, and travelled with a train of hunting-dogs after them, like nobles. The above date ſhould probably have been 1517, as Munſter himſelf owns, he never ſaw any till 1524. He adds, that they had paſſports from king Sigiſmund of Bohemia, and other princes. Ten years afterwards, they came into France, and thence paſſed into England. Several hiſtorians inform us, that when ſultan Selim conquered Egypt, in the year 1517, ſeveral of the natives refuſed to ſubmit to the Turkiſh yoke; but, being at length ſubdued and baniſhed,

they

they agreed to disperse in small parties over the world, where their supposed skill in the black art gave them an universal reception, in that age of superstition and credulity. In a few years the number of their proselytes multiplied, and they became formidable to most of the states of Europe. Pasquier, in his Recherch. lib. iv. chap. 19. relates a less probable origin of the *Gypsies*, thus: on the 17th of April 1427, there came to Paris twelve penitents, or persons, as they said, adjudged to penance, viz. one duke, one count, and ten cavaliers, or persons on horseback: they took on themselves the character of *Christians of the Lower Egypt*, expelled by the Saracens; who, having made application to the pope, and confessed their sins, received for penance, that they should travel through the world for seven years, without ever lying on a bed. Their train consisted of 120 persons, men, women, and children, which were all that were left of 1200, who came together out of Egypt. They had lodgings assigned them in the chapel, and people went in crowds to see them. Their ears were perforated, and silver buckles hung to them; their hair was exceedingly black, and frizzled; their women were ugly, thievish, and pretenders to telling of fortunes. The bishop soon afterwards obliged them to retire, and excommunicated such as had thrown them their hands. By an ordonnance of the states of Orleans, in the year 1560, it was enjoined all these impostors, under the name of *Bohemians* and *Egyptians*, to quit the kingdom, on penalty of the gallies. Upon this they dispersed into lesser companies, and spread themselves over Europe. The first time we hear of them in England was in the year 1530, when they were described by the statute already cited, 22 Hen. VIII. cap. 10. They were expelled from Spain in 1591. Du-Cange.

Ralph. Volsterranus, making mention of them, affirms, that they first proceeded or strolled from among the Uxii, a people of Persia or Persia.

EGYPTIAN *year*. See YEAR.

EHRETIA, in *Botany*, a genus of the *pentandria monogynia* class of plants, with a double-celled berry, single bilocular seeds, and a marginated stigma. There are four species.

EIA, or EY, in our *Old Writers*, are used for an island. Hence the names of places ending in *ey*, denote them to be islands. Thus, Ramsey, the isle of Rams; Sheppey, the isle of Sheep, &c.

EIA, is also sometimes used for water; and hence the names of places near waters, or lakes, terminate in *ey*.

EIDER-*duck*. See DUCK.

EJACULATION, in *Medicine*, the act of emitting seed, from the Latin, *ejaculari, to cast outwards*. See EMISSION.

EJACULATOR, in *Anatomy*, a name applied to two muscles of the genitals, from their office in the ejaculation of the seed.

The *ejaculatores* arise from the sphincter of the anus, and advance along the urethra as far as the middle thereof where they are inserted laterally.

The same denomination is like wise given to two muscles of the clitoris, which, arising from the sphincter ani, advance laterally along the labia, and are inserted aside of the clitoris.

EJACULATORY, in *Anatomy*, is a term applied to two little ducts, or canals, arising from the vesiculæ seminales. The *ejaculatory* ducts are about an inch in length: towards the vesiculæ, they are pretty wide; but they contract themselves as they approach towards the urethra, which they penetrate together.

Some authors also apply the name *ejaculatory* to the vasa deferentia.

EICETÆ, called also HEICETÆ and HICETÆ, heretics of the seventh century, who made profession of the monastic life.

From that passage in Exodus, where Moses and the children of Israel are said to have sung a song in praise of the Lord, after they had passed the Red-Sea, wherein their enemies had perished, the *Eicetæ* concluded, that they must sing and dance, to praise God aright; and as Mary the prophetess, sister of Moses and Aaron, took a drum in her hand, on the same occasion, and all the women did the like, to testify their joy, by playing, beating, and dancing, the *Eicetæ*, the better to imitate their conduct herein, endeavoured to draw women to them to make profession of the monastic life, and affect in their mirth.

EJECIT *infra terminum*. See QUARE *ejecit*.

EJECTION, the act of throwing out, or discharging any thing at some of the emunctories, as by stool, vomiting, or the like.

EJECTIONE *custodiæ*, *ejectment de garde*, in *Law*, a writ which lies against him that casts out the guardian from any land during the minority of the heir.

EJECTIONE *firmæ*, a writ that lies for the lessee for years, who is ejected before the expiration of his term, either by the lessor or a stranger.

Also *ejectment* may be brought by a lessor against the lessee, for rent in arrears, or holding over his term, &c. Reg. Orig. 227. But *ejectment* is now become an action in the place of many real actions, as writs of right, formedons, &c. which are very difficult, as well as tedious and chargeable; and this is the common action for trying of titles, and recovering of lands, &c. illegally kept from the right owner. Though, where entry is taken away by descents, fines, and recoveries, disseisins, &c. *ejectment* may not be brought; so that all titles cannot be tried by *this* action.

The method of proceeding in the action of *ejectment* is, to draw a declaration, and therein feign a lease for three, five, or seven years, to him that would try the title; and also feign a casual ejector or defendant; and then deliver the declaration to the ejector, who serves a copy of it on the tenant in possession, and gives notice in writing at the bottom, for him to appear and defend his title; or that he, the feigned defendant, will suffer judgment by default, whereby the true tenant will be turned out of possession: to this declaration the tenant is to appear, at the beginning of next term, by his attorney, and consent to a rule to be made defendant, instead of the casual ejector, and take upon him the defence; in which, he must confess lease, judgment, entry, and ouster, and at the trial stand upon the title only: but in case the tenant in possession does not appear, and enter into the said rule in time, after the declaration served, then, on affidavit being made of the service of the declaration, with the notice to appear, the court will order judgment to be entered against the casual ejector by default; and thereupon the tenant in possession, by writ *habere facias possessionem*, is turned out of his possession. On the trial in *ejectment*, the plaintiff's title is to be set forth from the person last seised in fee of the lands in question, under whom the lessor claims down to the plaintiff, proving the deeds, &c. and the plaintiff shall recover only according to the *right* which he has at the time of bringing his action. And here, another who had title to the land, upon a motion made for that purpose, may be defendant in the action, with the tenant in possession, to defend his title; for the possession of the lands is primarily in question, and to be recovered, which concerns the tenant, and the title thereto is tried collaterally, which may concern some other.

By a late statute, in all cases between landlord and tenant, when half a year's rent shall be in arrear, the landlord, having lawful right to re-enter for non-payment, may serve a declaration in *ejectment* on the tenant without a formal demand or re-entry; or he may affix such declaration on the door of the demised messuage, or notorious place of the lands, which shall be deemed a legal service; and upon proof that half a year's rent was due before the declaration was served, and no sufficient distress on the premisses, the lessor shall have judgment and execution; which if the lessee suffer without paying the arrears and costs, and without filing a bill in equity to be relieved within six months, he shall be barred from all relief, except by writ of error; and the lessee shall hold the premisses discharged from the lease; but if the tenant or lessee tender to the lessor, or bring into court the rent in arrear, together with costs, all further proceedings shall cease; and if the lessee be relieved in equity, he shall enjoy the demised premisses according to his lease, without obtaining a new one. Stat. 4 Geo. II. cap. 28. and 11 Geo. II. cap. 19.

EIGHT-FOIL, or *Double Quarter-foil*, in *Heraldry*, a modern DIFFERENCE, denoting the ninth son of the first house.

EIGHT, *piece of*. See PIECE *of eight*.

EIGHTH *pair of nerves*. See NERVE.

EIGNE, from French, *aîsne*, in *Law Books*, is used for eldest, or first-born. Thus we say, bastard *eigne*, and *mulier puisne*, for the elder bastard, and the younger lawfully born.

EILAMIDES, from ἑίλω, *I involve*, a word used by Hippocrates, to express the meninges, or membranes of the brain, the dura mater and pia mater.

EINBLINDER, in *Ichthyology*, the name of a sort of lamprey, without eyes, called by the writers on these subjects the *lampetra cæca*, or *blind lamprey*. It is very small, not exceeding the common dew-worms in length or thickness. It has no scales; but its body is divided by annular lines, into eighty-four rings, just in the manner of the large worms. Its mouth is in the under part of its head, and is round, and always open. It has a cavity in the middle of its head, like the rest of the lampreys, for admitting water, and has seven gill-holes on each side. It has the common long fin running on the ridge of the back, but has no other. Willughby's Hist. Pisc. p. 107.

ELNECIA, in our *Old Writers*, is used for primogeniture. It is sometimes writ *elnecia* and *elney*. See ELNECT.

ELRE, see EYRE.

ELRESIONE, ἐλρεσιώνη, from ἔλρος, *wool*, in *Antiquity*, an olive branch bound about with wool, and crowned with all sorts of first fruits, which was carried in procession in the Athenian festival, called PYANEPSIA. Port. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 228.

ELSETERIA, ἐλσετηρία, from ἕζομαι, *I enter*, in *Antiquity*, the day on which the magistrates at Athens entered upon their office; upon which it was customary for them to offer a solemn sacrifice, praying for the preservation and prosperity of the commonwealth, in the temple of Jupiter Βουλαίου, and Minerva Βουλαίας, i. e. the Counsellors. Port. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 385.

ELA *Cattli*, in *Botany*, the name of a shrub which grows in sandy soils, in some parts of the East Indies, about twice as high as a man. The bark of the root triturated, and drunk in water in which rice has been boiled or washed, is recommended against the dropsy, and is said to be a very mild medicine; which Mr. Ray justly wonders at, as the plant is full of an acrid caustic milk; which, however, when exhibited with butter in which it has been boiled, proves a mild and gentle purgative. The leaves heated at the fire, provoke urine; and the steam, or vapour of a decoction of them, contributes to alleviate and remove pains in any part of the body. The juice, expressed from the leaves, either warmed or a little toasted, cures pains of the ears, if put into them. It also removes specks in the eyes, if dropt into them, and contributes to the cure of swellings in the pudenda, if the body is washed with it.

ELABORATION, the act of finishing or perfecting any thing with labour and time.

The term is chiefly used in *Medicine*, where the chyle, blood, and semen, are said to be *well elaborated*, when they are well conditioned, have undergone all the secretions, mixtions, impregnations, and circulations, necessary to bring them to perfection.

If the chyle went directly from its receptaculum to the breasts, it would not be sufficiently *elaborated* to afford good milk. See BILE.

ELABORATORY. See LABORATORY.

ELÆONON. See AGNUS *Castus*.

ELÆAGNUS, in *Botany*, a name used by some authors for the gale-brutes, the Dutch myrtle or gaule. Merret. Pin. p. 182.

ELÆAGNUS, in *Botany*. See *Wild* OLIVE.

ELÆOCARPUS, in *Botany*, a genus of plants of the *polyandria monogynia* class; the calyx of which is a five-leaved perianthium; the corolla consists of five torn petals, the fruit a drupe, and the seed a crisp nucleus. There is one species.

ELÆOMELI, in the writings of the ancient *Physicians*, the name of a fusillance, thus described by Dioscorides. In Palmyra, a country of Syria, the *oleomeli*, which is an oil thicker than honey, and of a sweet taste, flows from the trunk of a tree. Two cyathi of this oil, he adds, drunk with a hemina of water, evacuate crude and bilious humours by stool. There was much good obtained from the giving of this medicine: but it had this remarkable effect, that those who took it were seized with a torpor, and privation of strength for a time: this was, however, of no ill consequence, but people knew of and expected it, and used always to keep those persons awake who had taken it, and the symptoms soon went off. The same author also adds, that the oil was sometimes prepared from the buds of the tree; and such of this kind was esteemed the best that was old, thick, fatty, and not foul or turbid. It was judged of a heating nature, and frequently applied externally to the eyes, with good effect in the cure of dimness of sight, and contributed to the cure of leprosies, and pains of the nerves. Hermolaus Barbarus has a strange conjecture in regard to the substance, which is, that it was the same with the manna mentioned in Scripture, only used in medicine instead of food: but the account which Dioscorides gives of the effects of it is a very sufficient answer to the absurdity of such an opinion. Dioscorides, lib. i. cap. 37.

ELÆOSACCHARUM. See ELEOSACCHARUM.

ELÆOTHESIUM, ἐλαιοθέσιον, in *Antiquity*. See ATHLETICUM.

ELÆS, in *Botany*, a genus of the class of *polygamia*: both the male and female flowers have a six-leaved calyx; the corolla of the male is divided into six segments, and that of the female has six petals; the stamina of the former are six, and the stigmata of the latter three; the fruit is a fibrous drupe, containing a single three-valved nut.

ELANULA, in *Astronomy*, the name of a peculiarly hard alum.

ELAPHEBOLIA, ἐλαφηβολία, in *Antiquity*, a festival kept in honour of Diana ἐλαφηβόλος, i. e. the Huntress, for which reason, a cake made in form of a stag, and upon that account called ἐλαφος, was offered to her. For a further account of it, see Port. Archæol. Græc. lib. ii. cap. 20.

ELAPHEBOLION, ἐλαφηβολιών, in ancient [illegible] the ninth month of the Athenian year. It [illegible] thirty days, and answered to the latter part of [illegible] ary, and beginning of March. See MONTH.

It was thus called from the festival ELAPHEBOLIA kept in it.

ELAPHIS. See ELAPS.

ELAPHOBOSCUM, in *Botany*, the wild parsnep. See PARSNEP.

ELAPHOCAMELOS, in *Zoology*, a name by which several authors have called the Peruvian camel, usually called *glama*, and employed there as a beast of burden. See GLAMA.

ELAPHONESUM *marmor*, a name used by the ancients to express a species of marble used in statuary, and called also *Proconnesium marmor*; it was of a bluish white, variegated with slender veins of black. See PROCONNESIUM.

ELAPS, or ELAPHIS, by some called also *elops*, the name of a serpent described by many authors, and met with by Belloninus in the island of Lemnos: it grows to about three feet long, and is on the back of a dark grey, with three longitudinal black lines, running from the head to the tail, and on the belly of a bright yellow, according to Aldrovandus. The people of Lemnos call it *ichthiatis*.

ELASMIS, in *Natural History*, the name of a genus of fossile bodies, of the talc class, the distinguishing characters of which are, that they are composed of small plates, in form of spangles, each of which is either single, and not farther fissile; or, if compact, fissile only to a certain degree, and that into somewhat thick lamina. See *Tab. of Fossils, Class* I.

The word is derived from the Greek, ἔλασμα, *a lamina* or *plate*: the several component parts of these masses being so many small plates.

The bodies of this genus have been used to be named *mica*, *glimmer*, and *talc-stone*, by authors, in the same manner with the *tractatæ*. There are only four known species of this fossile.

ELASTIC *body*, in *Mechanics*, is that which, by being struck or stretched, has its figure altered; but endeavours, by its own force, to resume the same: or, it is a springy body, which when compressed or condensed, or the like, makes an effort to set itself at liberty, and to repel the body that constrained it. Such is a sword-blade, a bow, &c. which are easily bent, but presently return to their former figure and extension. This property belongs more or less to almost all bodies; but as there are none which restore themselves with the same force with which they were compressed, there are no bodies that are perfectly *elastic*.

The word is formed from the Greek, ἐλαστὸς, *impulsus*, *ab* ἐλαύνω, *to impel, push, &c.* See SPRING.

Elastic bodies are either *natural* or *artificial*: those most eminent for their *elastic* power, among *artificial* bodies, are steel, brass, ivory, and marble balls; leather, skins, membranes; brass, silver, iron, and steel chords or wires; nerves, guts, hemp, and flax strings, &c.

Amongst *natural bodies*, the principal are air, sponges, the branches of green trees, wool, cotton, feathers, &c. It is disputed, whether or no water hath any *elastic* force: the most common opinion has long been, that it has none of itself; and that if it shews any, it is owing to the air contained therein. See CONDENSATION, under which article the contrary is demonstrated.

The principal phenomena observed to obtain in *elastic bodies*, are, 1. That an *elastic body*, i. e. *a body perfectly elastic*, if any such there be, endeavours to restore itself with the same force wherewith it is pressed or bent.

2. An *elastic* body exerts its force equally towards all sides; though the effect is chiefly found on that side where the resistance is weaked; as is evident in the case of a bow shooting out an arrow, a gun exploding a ball, &c.

3. *Elastic bodies*, in what manner soever struck, or impelled, are inflected, and rebound after the same manner. Thus a bell yields the same sound in what manner, or on what side soever it be struck.

4. A body perfectly fluid, if any such there be, cannot be *elastic*, if we allow that its parts cannot be compressed. See FLUID.

5. A body perfectly solid, if any such there be, cannot be *elastic*, in that having no pores, it is incapable of being compressed. See SOLID.

6. Hard, long, flexible bodies, apt to acquire *elasticity*, do

do it chiefly in three ways; either by being extended, by being contracted, or by being bent.

7. Bodies, in dilating themselves by their *elastic* power, exert a greater force at the beginning of their dilatation, than towards the end thereof; because the bodies are more compressed at first, and the tenitency is always equal to the compression.

8. The motion, whereby compressed bodies restore themselves, is usually an accelerated motion. See DILATATION.

9. The *elastic* property of bodies seems to differ, according to their greater or less compactness or density: thus, metals, by being hammered, are rendered more compact, and also more *elastic*. Tempered steel is much more *elastic* than soft steel; and the density of the former to the latter as 7899 to 7778. Cold likewise condenses bodies, and renders them more *elastic*; whilst heat, that relaxes them, has the contrary effect. M. Belidor has found, that cannon balls are projected farther from cold guns, than from the same guns, when heated; and the firing of a violin is known to act more strongly in winter than in summer. We must except, however, air, and other *elastic* fluids, which acquire an increase of *elastic* force from heat. Muschenb. Int. ad Phil. Nat. vol. i. p. 231. 4to.

We may add, 10. That the *elastic* force of bodies is the same in vacuo as in the air, when other circumstances are alike.

For the laws of motion and percussion in *elastic* bodies, see MOTION and PERCUSSION.

ELASTIC CURVE. See CATENARIA.

ELASTICITY, or ELASTIC *Force*, in *Mechanics*, denotes a property or power in natural bodies, which denominates them *elastic*; and by which they are restored to the figure and extension they had loft from any external cause.

The cause, or principle, of this well-known and important property is variously assigned: the Cartesians account for it from the effort of the *materia subtilis* to pass through pores that are too narrow for it. Thus, say they, in bending or compressing an elastic body, e. gr. a bow, its parts recede from each other on the convex side, and approach on the concave; consequently, the pores are contracted or straitened on the concave side; and if they were before round, they are now oval; and the materia subtilis endeavouring to pass out at those pores, thus straitened, must make an effort, at the same time to restore the body to the first state it was in when the pores were more patent and round, i. e. before the bow was bent. Other philosophers account for *elasticity* much after the same manner as the Cartesians, with this inconsiderable difference, that, instead of the subtile matter of the Cartesians, they substitute a fine etherial medium that pervades all bodies. Others again have supposed, that this subtile matter or ether is itself *elastic*.

Some resolve *elasticity* into the pressure of the atmosphere; for a violent tension or compression, though not great enough to separate the constituent particles of bodies far enough to let in any foreign matter, must yet occasion many little cavities between the separated surfaces; so that upon the removal of the force they will close again, by the pressure of the aerial fluid upon the external parts. Others make the elastic force of the air included within the pores of all bodies the principle of their *elasticity*; but this hypothesis is contrary to fact; since the elastic force remains *in vacuo*. Malebranche, and others after him, have ascribed this property to imaginary vortices of matter included within all bodies, whose spherical figure is changed by compression into an oval figure, and whose centrifugal force restores them, together with the parts of bodies to which they belong, to their former state.

Others account for *elasticity*, from the great law of nature, attraction, or the cause of the cohesion of the parts of solid and firm bodies. Thus, say they, when a hard body is struck or bent, so that the component parts are removed a little from each other, but not quite disjoined, or broke off, or separated so far as to be out of the reach of that attracting force whereby they cohere; they must certainly, on the cessation of the external violence, spring back to their former natural state. But it has been objected to this hypothesis, that when, e. gr. a spring is bent, the particles on the convex side will be separated from one another, whilst those on the concave will be brought nearer, and the power of attraction, instead of making the spring restore itself, will keep it in the same state, as it happens in bodies that have no *elasticity*, where perhaps only attraction obtains; and therefore they have supposed the constituent particles of bodies to be endued with both a repulsive and an attractive power: thus, if a row of round particles touch one another in the point; in a line from A to B (*Tab.* III. *Mechanics*, *fig.* 36.) it is plain, from the laws of cohesion, that upon the least alteration out of the position of a straight line, these particles will run together, and form a sphere, in which the globules will have more points of contact; and if these particles are supposed to have poles like magnets, in the opposite places marked *n*, *s*, &c. that all the poles *n*, *n*, *n*, &c. repel one another, and all the poles *s*, *s*, *s*, &c. repel one another, the line A B will continue straight; for if by any force the said line B A be put into another position, as in the curve *b a*, then the poles *n*, *n*, &c. being brought nearer together, while the poles *s*, *s*, &c. are farther asunder, will repel one another more strongly, and thereby hinder the globules from running together towards the concave part, and the spring left to itself, one end as *b*, B, or *a* being fixed, will restore itself, throwing its end *a* back to A, and so on to *a*, then, being in the position *a* B, the poles *s*, *s*, &c. are brought nearer together, whose repulsion, thus increased, throws back *s* to *b*, and so on forward, whilst the line of particles performs several vibrations round B. A spring of steel, or other springs, may probably consist of several series of such particles, whose polarity and attraction acting at the same time will shew, why such bodies, where they have been bent, vibrate and restore themselves. Hard steel is highly *elastic*, and the metal is thus hardened by making it white-hot, and immediately quenching it, so that it is fixed in an almost fluid state, and the particles which the fire had made almost round have but a very small contact; and accordingly, steel thus hardened is extremely brittle: but as spherical particles can never make a tough spring, the workmen bring down the temper of the hard steel, or *let down the spring*, as they express it, by a process which alters the figures of its constituent particles. For this purpose they heat it anew, and whilst it is gently cooling, the mutual attraction increases the contact, so that the particles grow flatter in those places where before they had but a small contact; and left the contact should become too great, they quench the spring in water, oil, or grease. Or they have another process, which is to shape them in cold unmalleable steel, and then heating them to a small degree, e. gr. to a blood-red heat, immediately to cool them in some proper liquor; whereby the particles are fetched in their oblong figure before they become round in the fusion of a white heat. Nor is it improbable that they may thus acquire polarity, since dipping red-hot steel in cold liquors in a particular position will make it magnetical: and iron and steel are also made magnetical only with hammering. Desaguliers's Course of Exper. Phil. vol. ii. p. 38—40, &c. See SPRING. Perhaps the true cause of the *elasticity* of bodies may still remain among the unexplored secrets of nature.

ELASTICITY, *laws of*. To enquire a little more expressly into the nature and laws of *elasticity*, we shall consider the phenomena thereof. Let it be premised, then, that all the bodies wherein this power is observed, do consist, or may be conceived to consist, of small threads or fibres, which, laid together, constitute such bodies. To examine *elasticity*, therefore, in its most simple case, we had best consider it in musical strings or chords, and particularly in those of metal; for those of cat-gut, having a spiral twist, cannot be considered as the fibres wherein bodies are formed.

Now the *elasticity* of a fibre, or chord, consists in this: that it may be stretched or extended; and that upon removing the force whereby it was stretched or lengthened, it returns again to its former dimensions. Fibres have no *elasticity*, unless they be extended with a certain force; as appears in lax chords, which may be moved a little out of their position without endeavouring to recover it; though what the degree of tension is, necessary for *elasticity* to commence, is not yet determined by experiment: add, that when a fibre is too far stretched, it loses its *elasticity*; though here, too, the degree of tension that destroys *elasticity* is unknown; but it is certain, *elasticity* depends on tension, and is confined within a certain sphere, or boundary thereof, on either side. See SYMMO. This, if it doth not give us the proper adequate cause of *elasticity*, yet shews us the difference between *elastic* and *unelastic* bodies; how it is that a body loses its *elasticity*, and how a body, destitute of any such force, comes to acquire it. Thus, a plate of metal, by repeated blows of a hammer, becomes *elastic*; and, being heated again, loses that property.

Between the limits of tension, wherewith *elasticity* is terminated, there are different forces required to give different degrees of tension, in order to stretch chords to certain lengths; what the proportion of these forces is, can only be determined by experiments made with chords of metal; but as the lengthenings of such chords are scarce sensible, the proportions cannot be directly measured; but a particular apparatus, and a kind of circuit, are necessary to arrive thereat. Dr. s'Gravesande has

when

taken a good deal of pains, in order to fix theſe laws, the reſults of whoſe experiments are as follow:

1. That a weight, whereby a fibre is increaſed a certain length, by ſtretching, is, in different degrees of tenſion, as the tenſion itſelf; if, e. g. there be three fibres of the ſame kind, length, and thickneſs, whoſe tenſions are as 1, 2, and 3; any weights, in the ſame proportion, will ſtretch them equally.

2. That the leaſt lengthenings of the ſame fibres are to one another nearly as the forces whereby the fibres are lengthened; which property may likewiſe be applied to their inflection.

3. In chords of the ſame kind and thickneſs, and which are equally ſtretched, *out* of different lengths, the lengthenings produced by ſuperadding equal weights, are to one another as the lengths of the chords; which ariſes hence, that the chord is lengthened in all its parts; conſequently, the lengthening of a whole chord is double the lengthening of half of it, or a chord of half the length.

4. Fibres of the ſame kind, but of different thickneſſes, may be compared together after the like manner; only conſidering them as conſiſting of a greater or leſs number of fine fibres of the ſame thickneſs; the number whereof muſt be taken in the ratio of the ſolidity of thoſe fibres, i. e. as the ſquares of the diameters, or as the weights of theſe fibres, when their lengths are equal: ſuch fibres, of conſequence, will be equally ſtretched by forces that are in the ſame ratio of the ſquares of the diameters; which ſame ratio is likewiſe required between the forces whereby the chords are inflected, that the ſagitæ may be equal in the given fibres.

5. The motion of a ſtretched fibre agrees with the motion of a body vibrating in a cycloid; and how unequal ſoever the vibrations are, they are all regularly performed in the ſame time.

6. In two equal chords, unequally ſtretched, unequal forces are required to inflect them equally: their motions may be compared to thoſe of two pendulums, deſcribing ſimilar cycloids, by different forces; conſequently, the ſquares of the times of the vibrations of the fibres are to each other inverſely as the forces whereby they are equally inflected, or as the weights by which the chords are ſtretched.

7. The motions of ſimilar chords, equally ſtretched, but of *different lengths*, may be compared with that of pendulums after another manner; for as the times of the vibrations are to be conſidered, the celerities alſo, wherewith the chords are moved, muſt be conſidered. Now theſe celerities are to one another directly as the weights wherein the chords are inflected, and inverſely as the quantities of matter in the chords; that is, inverſely as their lengths: the celerities, therefore, are in an inverſe duplicate ratio of thoſe lengths; that is, they are inverſely as the ſquares of the lengths; and the ſquares of the times of the vibrations are likewiſe in the inverſe ratio; conſequently, the lengths of the chords will be as the times of the vibrations.

Elaſtic lamiuæ, or plates, may be conſidered as ſegaries, or ſtuntſes, of *elaſtic* chords. When the plate is inflected, ſome fibres are lengthened; and there are unequal lengthenings in ſeveral points of the ſame plate.

The curve formed by the inflected plate is eaſily determined, from what has been ſhewn concerning chords: in effect, in the vibrations of ſuch plate or ſpring, the motion thereof is accelerated, after the ſame manner as the motion of a chord, and of a pendulum in a cycloid, is accelerated; and the vibrations of ſuch ſprings are all performed in the ſame time.

Elaſtic balls, ſpheres, &c. may be conſidered as conſiſting of ſeveral *elaſtic* plates, or ſprings; and the introceſſions, or yieldings inward, of any point thereof, are proportionable to the forces wherewith the body is compreſſed.

The ELASTICITY *of fluids* is accounted for, from their particles being all endued with a centrifugal force; whence Sir Iſaac Newton, prop. 23. lib. ii. demonſtrates, that particles, which mutually avoid, or fly off, from one another, by ſuch forces as are reciprocally proportional to the diſtances of their centres, will always compoſe an *elaſtic fluid*, whoſe denſity ſhall be proportional to its compreſſion; and, *vice verſa*, if any fluid be compoſed of particles that fly off and avoid one another, and hath its denſity proportional to its compreſſion; then the centrifugal forces of thoſe particles will be reciprocally as the diſtances of their centres.

ELASTICITY *of the air* is the force wherewith that element endeavours itſelf, upon removing the force whereby it was before compreſſed.

The *elaſticity*, or *ſpring of the air*, was firſt diſcovered by lord Bacon, and farther eſtabliſhed by the great Galileo. See *Elaſticity of* AIR.

O

Its exiſtence is proved by this experiment of that philoſopher; let an extraordinary quantity of air be introduced, by means of a ſyringe, into a glaſs or metal bottle, till, in time as the ball, with this acceſſion of air, weighs conſiderably more, in the balance, than it did before; upon opening the mouth thereof, the air rufhes out, till the ball links to its former weight.

From hence we argue, that there is juſt ſo much air gone out, as the compreſſed air which had been crouded in. Air, therefore returns to its former degree of expanſion, upon removing the force that compreſſed, or reſiſted, its expanſion; and, conſequently, it is endued with an *elaſtic force*.

It muſt be added, that as the air is found to ruſh out, in every ſituation or direction of the orifice; the *elaſtic force* of the air acts every way, or in every direction.

The *elaſticity of the air* making a conſiderable article in the new pneumatics, we ſhall here give the principal laws thereof.

1. The *elaſticity* of the lower air is equal to the weight of all the upper incumbent air; for the upper air is eaſily proved to preſs on the lower.

And the *elaſticity of the air* has already been ſhewn equal to the compreſſing power; whence it follows, that the *elaſticity of the air* is equal to the weight of the whole incumbent atmoſphere.

Hence as the weight of the upper air, incumbent on the lower, is equal to the weight of a column of water of the ſame diameter with the column of air, and the altitude of 32 feet; or to a column of mercury 28 inches high; the ſpring of the lower air is equal to the ſame column of water, or mercury.

Hence, again, the ſpring of the air, included in a veſſel, &c. is likewiſe equal to the weight of the whole incumbent atmoſphere: conſequently, the air, included in a veſſel, preſſes with the ſame force as the weight of the atmoſphere; and therefore the *elaſticity* of the included air is able to ſuſtain mercury to the height of twenty-eight inches, and water to the height of thirty-one feet, in an empty tube.

2. The *elaſtic force* of air compreſſed, is to that of the ſame air dilated, reciprocally as the bulk of the dilated air to that of the compreſſed air.

For the *elaſticity of air* more compreſſed, is to that of air leſs compreſſed, as the weight incumbent on that to the weight incumbent on this; but the bulks of more and leſs compreſſed air are in the ſame reciprocal ratio of theſe weights; therefore the *elaſtic force*, &c.

Hence the *elaſticity of air* more compreſſed, is ſtronger than that of air leſs compreſſed.

3. The *elaſticity* of more compreſſed air, is to that of air leſs compreſſed, *ceteris paribus*, as the mafs, or quantity, of more compreſſed air is to a maſs of air leſs compreſſed of the ſame bulk.

4. The ratio of the ſpace filled by air preſſed only by the weight of the atmoſphere, to the ſpace it is reduced into by farther compreſſion, being given; to determine the *elaſtic force* of the compreſſed air.

Since the ſpring of the air, preſſed only by the weight of the atmoſphere, is equal to the weight of a column of mercury, of the ſame baſe with the column of air, and of the height of twenty-eight inches; to the bulk of the compreſſed air, that of the air not compreſſed, and the weight of the column of mercury, ſeek a fourth proportional; this will expreſs the quantity of the *elaſtic force* in the compreſſed air.

Hence ſubtracting the weight of the column of mercury from the quantity of the *elaſtic force* thus determined, the remainder is the force of *elaſticity* whereby it exceeds the reſiſtance of the weight of the atmoſphere.

5. Heat increaſes the *elaſticity* of the air, and cold diminiſhes it. See HEAT, and COLD.

6. The *elaſtic force* of the air, whereby it is expanded, in rarefaction, is to the *elaſticity* of the air condenſed, as the bulk of rarefied air, to the bulk of condenſed air.

ELATE, in *Botany*, a genus of the claſs of *palmæ*. They have male and female flowers, whoſe calyx is not aſcertained; the corolla in each has three petals; the male has three ſtamina; the female a ſingle piſtil; the fruit is an oval acuminated drupe.

Elate, is alſo uſed, by ſome authors, for a genus of plants called by Linnæus *phoenix*, and, in the Hortus Malabaricus, *ratvenhola*. See PHOENIX.

This word was alſo uſed by the ancients to expreſs the ſtrong; and likewiſe in other ſenſes.

ELATER, the name of a genus of the *coleoptera* order of inſects, with ſtraceous antennæ; which, when laid on their backs, have a power of leaping with great force and agility. There are various ſpecies of theſe four-winged flies, diſtinguiſhed by their different colours.

ELATERIUM, in *Botany*, a genus of the *monœcia monandria* claſs. This genus hath male and female flowers in the

the same plant; neither have any calyx; the corolla in both is hypocrateriform, or salver-shaped; the capsule is single-celled, with two valves. Miller makes the *elaterium* of Boerhaave, or the wild cucumber, a species of the *momordica*. See *Male* BALSAM *Apple*.

ELATERIUM, ἐλατήριον, in *Pharmacy*, a violently purgative medicine, prepared from the wild cucumber. See *Male* BALSAM *Apple*.

The word is formed from the Greek ἐλαύνω, *I impel, agitate, &c.*

Elaterium is made of the juice of the fruit, forced out with the finger; this, suffered to stand some time, lets fall a sediment, which, carefully dried on chalk-stones, is the *elaterium*.

Elaterium is a vigorous purge, and is sometimes used in lethargies, palsies, and hypochondriacal melancholies.

ELATINE, in the Linnæan system of *Botany*, is a distinct genus of plants of the *octandria tetragynia* class; the characters of which are, that it has a four-leaved calyx, four petals, a four-celled depressed capsule, with four valves. There are two species.

ELATINE, *Fluellin*, or *Female Speedwell*, is, in Linnæus's distribution, a species of the ANTIRRHINUM; under which genus he has also classed the LINARIA. Miller makes the *elatine* a species of the *linaria*, or *toad-flax*. This is a low procumbent plant, with oval, acuminated, downy leaves, set alternately on the stalks. It is annual, grows wild in corn-fields, and flowers in July.

ELATINE, in *Medicine*, is greatly recommended as an aperient, resolvent, and vulnerary. Its simple water has been used for the same purposes, though it retains very little of the virtues of the plant. The infusion is much better, and the expressed juice preferable still. It is praised by some in leprous and scrophulous cases; also externally for cancerous and other eating ulcers. An ointment is made of it for these purposes. At present, however, it is very little used.

A combination of its active matter with honey, prepared by boiling four pints of the depurated juice with four pounds of clarified honey, is sometimes kept in the shops.

ELATITES, *fir-stone*, in *Natural History*, a name given by authors to that sort of petrified wood which shews the lineaments of the fir-tree wood, and has been originally either that or some wood of a like kind.

ELATITES was also a name used by the ancients for an iron ore, esteemed a species of hæmatites; it was of a yellowish white colour, and was more usually called XANTHUS.

ELAWANDUM, in *Zoology*, the name of a remarkable species of monkey, common in the island of Ceylon: its hair is whitish, or of a pale grey, and it has a long and beautiful black beard hanging from its chin. Ray's Syn. Quad. p. 188.

ELBOW, the outer angle made by the flexure, or bend of the arm.

That eminence whereon the arm rests, called by us *elbow*, is by the Latins called *cubitus*, and the Greeks ἀγκών, and by others ὠλένη.

ELBOW is also used by architects, masons, &c. for an obtuse angle of a wall, building, or road, which diverts it from its right line.

ELCESAITES, HELCESAITES, or ELCESAIANS, as Theodoret calls them, ancient heretics, thus denominated from their great prophet *Elcesai*.

This Elcesai, by others called Elxai, who lived in the time of Trajan, gave into the sentiments of the Ebionites, touching Jesus Christ; though he altered and reformed them in some things, to denominate himself the author of a sect.

His fundamental doctrines were, that Jesus Christ, who was born from the beginning of the world, had appeared from time to time under divers bodies; that he was a celestial power, or virtue, called *the Christ*, whereof the Holy spirit was sister (note the Hebrew word for spirit is feminine); and that both of them had descended into *Jesus*, the son of Mary, who was clothed with a corporeal appearance, but not with a real body.

The *Elcesaites*, according to St. Epiphanius, were by some also called *Sampsæans*, from the Hebrew word *shemes*, *sun*. Scaliger was notoriously mistaken, in holding, that *Elxai* was no more than *Esau*, or *Esseus*; on which supposition he made the *Elcesaites* the same with the sect of Esseus, which is contrary to all antiquity.

Origin makes mention of the *Elcesaites*, in one of his homilies as a heresy newly risen. The retainers hereto, says he, do not admit all the books of the canon, but only some of them: they allow some passages out of the Old Testament and the Evangelists, but reject all the Epistles of St. Paul. *Add*, that they have produced a book, which they pretend descended to them from heaven; and maintain, that whoever performs what is enjoined therein, shall obtain pardon of all their sins. See Eusebius, Hist. lib. vi. cap. 38. who remarks, that this heresy became extinct almost as soon as it arose.

St. Epiphanius is very full on the subject of this sect. Her. 19. where he observes that Elxai was a Jew by birth; and that not being able to live according to the law of Moses, he invented new opinions, and gained followers. He was a professed enemy of virginity, and obliged all, who followed his doctrine, to marry. He tutored them to hypocrisy in times of persecution; pretending it was lawful to adore idols, provided the heart had no share therein.

Some have doubted, whether the *Elcesaites* should be reckoned among the Christian or Jewish sects; for though they acknowledged Christ as a great king, it is not certain whether they meant Jesus Christ, or some other pretended Messiah.

ELDER, a word used in some parts of the kingdom for fuel. Dict. Rust.

ELDER-*tree*, *Sambucus*, in *Botany*, a genus of the *pentandria trigynia* class. Its characters are these: the flower hath a small permanent empalement of one leaf, cut into five parts: it hath one concave, wheel-shaped petal, cut into five obtuse segments at the brim, which are reflexed; and five awl-shaped stamina, of the length of the petal, terminated by roundish summits, with an oval germen situated under the flower, having no style, in room of which is a swelling gland, crowned by three obtuse stigmas; the germen afterward becomes a roundish berry, with one cell, including three angular seeds. Linnæus enumerates four, and Miller five species.

The common *elder* is too well known to need a description. Of this there are the following varieties, viz. the white and green-berried *elder*, and the variegated-leaved *elder*. For the medical virtues of that species, called the *dwarf elder*, see EBULUS.

The common *elder* will grow on any soil, or in any situation; the trees are frequently seen growing out of old walls, or close to ditches, in very moist places, or from the hollow of another tree; for wherever the seeds are scattered, the plants will come up. The leaves and stalks are so bitter and nauseous, that few animals will browse upon them.

The young shoots of this tree are very full of pith; but as the trees grow old, the wood becomes very hard, and will polish almost as well as the box-tree; and is often used for the same purpose.

The bark, leaves, flowers, and berries of this tree, are used in medicine. The inner bark is esteemed good for dropsies. Sydenham directs three handfuls of the inner bark to be boiled in a quart of milk and water, till only a pint remains, of which one half is to be taken in the morning, and the other at night; and this repeated every day. Boerhaave recommends the expressed juice of the middle bark, given from a dram to half an ounce, as the best of hydragogues, when the viscera are found. The leaves, which are said to be purgative and emetic, are outwardly used for the piles and inflammations. The flowers are inwardly used to expel wind; infusions made from them while fresh are gently laxative and aperient; when *dry*, they are said to promote the cuticular excretion, and to be particularly serviceable in erysipelatous and eruptive disorders; and the berries are esteemed cordial, and useful in hysteric disorders; and are frequently put into gargarisms for sore mouths and throats. Miller and Lewis.

Officinal preparations of the *elder*, are the *aqua florum sambuci*, the *oleum sambucinum*, the *unguentum sambucinum*, made of the leaves and inner bark, and also of the flowers, and the *syrupus sambuci*.

On the trunk of this tree frequently grows a fungous excrescence, wrinkled, and turned up like an ear, whitish on the outside, and black within, with several little veins. These are called Jews-ears, *auriculæ Judæorum*; they are accounted good for inflammations and swellings of the tonsils, sore throats, and quinzies.

ELDER, *marsh*, or *water*. See WAYFARING-*tree*.

ELDER, *Spanish*. See LIZARD'S *Tail*.

ELDERS, *Seniores*, in the *Jewish History*, were the most considerable persons, for age, experience, and virtue, among that ancient people. Moses, we read, assembled the *elders* of the people together, and acquainted them with what the Lord had commanded.

Long afterwards, those who held the first rank in the synagogues were usually called זקנים, *zekenim*, *elders*, in imitation of the seventy *elders*, whom Moses established for the judges of the sanhedrim. Numbers xi. 16, 17, 24, 25. Exod. xxiv. 1, 9, 14. See SANHEDRIM.

The president, or chief, had, in a particular manner, the appellation of *elder*; being, as it were, the *decanus seniorum*, *dean of the elders*.

In the assemblies of the primitive Christians, those who

held the firſt place, or rank, aſſumed the denomination of preſbyters, or *elders*; for the word *preſbyters*, which occurs ſo frequently in the Old Teſtament, and which includes alike both biſhops and prieſts, does properly ſignify *elders*. See M. Simon's obſervation thereon, in his Supplement aux Ceremonies des Juifs.

The preſident, or biſhop, as being the chief of the *elders*, did likewiſe aſſume the denomination of *elder*; whence it is, that in the New Teſtament the name *biſhop* is frequently confounded with that of *preſbyter*. See BISHOP, and PRESBYTER.

For the like reaſon, the council of the firſt churches was called *preſbyterium*, or council of the *elders*, where the biſhop preſided in quality of firſt *elder*, being ſeated in the middle of the other *elders*. The prieſts, or *elders*, who ſat by him, had each his judge's chair; for which reaſon they are called, by the fathers, *aſſeſſores epiſcoporum*. Nothing of any importance was done till it had firſt been examined, and reſolved, in this aſſembly, where the biſhop only made one body with the other *elders*, or prieſts; the juriſdiction which we now call epiſcopal, not being then dependent on the biſhop alone, but on all the *elders*, over whom he was only the preſident.

ELDERS is alſo a denomination ſtill retained in the preſbyterian diſcipline.

The *elders* are officers, who, in conjunction with the paſtors, or miniſters, and deacons, compoſe the conſiſtories, or kirk-ſeſſions, meeting to conſider, inſpect, and regulate matters of religion and diſcipline. They are choſen from among the people, and are received publicly with ſome degree of ceremony. In Scotland, there is an indefinite number of *elders* in each pariſh; generally about twelve. See KIRK-*Seſſion*, and PRESBYTERY.

ELDRIENE, in *Ichthyology*, a name by which ſome call the ſmall fiſh, known in Engliſh by the name of the MINOW, and called by authors VARIUS, from the various colour of its ſides and belly.

ELEATIC *philoſophy*, among the *Ancients*, a name given to that of the STOICS, becauſe taught at ELEA, in Latin Velia, a town of the Locani.

The founder of this philoſophy, or of the *Eleatic* ſect, is ſuppoſed to have been Xenophanies, who lived about the fifty-firſt Olympiad, or between five and ſix hundred years before Chriſt. This ſect was divided into two parties, which may be denominated metaphyſical and phyſical; the one reflecting, and the other approving, the appeal to fact and experiment. Of the former kind were Xenophanes, Parmenides, Meliſſus, and Zeno, of Elea. They are ſuppoſed to have maintained principles not very unlike thoſe of Spinoza; they held the eternity and immutability of the world; that whatever exiſted was only one being; that there was neither any generation nor corruption; that this one being was immoveable and immutable, and was the true God; and whatever changes ſeemed to happen in the univerſe, they conſidered as mere appearances and illuſions of ſenſe. However, ſome learned men have ſuppoſed, that Xenophanes and his followers, ſpeaking metaphyſically, underſtood by the univerſe, or the one being, not the material world, but the originating principle of all things, or the true God, whom they expreſly aſſert to be incorporeal. Thus Simplicius repreſents them as merely metaphyſical writers, who diſtinguiſhed between things natural and ſupernatural; and who made the former to be compounded of different principles. Accordingly, Xenophanes maintained, that the earth conſiſted of air and fire, that all things were produced out of the earth, and the ſun and ſtars out of clouds, and that there were four elements. Parmenides alſo diſtinguiſhed between the doctrine concerning metaphyſical objects, called truth, and that concerning phyſical or corporeal things, called opinion; with reſpect to the former, there was one immoveable principle; but in the latter two that were moveable, viz. fire and earth, or heat and cold; in which particulars Zeno agreed with him. The other branch of the *Eleatic* ſect were the atomic philoſophers, who formed their ſyſtems from their attention to the phenomena of nature; of theſe the moſt conſiderable were Leucippus, Democritus, and Protagoras. See EPICUREANS, and STOICS. See a further account of the opinions of theſe ancient philoſophers, in Cudworth's Intellectual Syſtem.

ELECAMPANE, *Inula*, in *Botany*, a genus of the *ſuperfluæ polygamia ſuperflua* claſs. Its characters are theſe: it has a radiated compound flower, with an imbricated ſcale; the diſk or middle of the flower is compoſed of hermaphrodite flowers; the border or ray of female half-florets ſtretched out like a tongue. The hermaphrodite flowers are funnel-ſhaped, and cut into five parts at the top; theſe have five ſhort, ſlender ſtamina, which coaleſce at the top; and they have only one long germen crowned with down. The female half-florets have narrow, entire, tongue ſhaped petals, no ſtamina, but a long crowned germen, with a hairy ſtyle. The germina in both flowers become a ſingle, narrow, four-cornered ſeed, crowned with a down, ſitting on a naked receptacle. Linnæus enumerates twenty-four, and Miller fifteen ſpecies; the firſt of which grows naturally in ſeveral parts of England, but is cultivated in gardens for the ſake of the roots. Miller.

Tournefort joins moſt ſpecies of this genus to the *aſter*, or *ſtarwort*. Ray claſſes it under the *helenium*.

The root of the *inula*, or *elecampane*, has been long famous in all diſorders of the breaſt and lungs. It is alſo recommended as a ſudorific and alexipharmic, and as ſuch, has a place in moſt of the compoſitions of that intention. Taken freely, it is ſaid to gently looſen the belly, and increaſe the urinary diſcharge. The doſe of the dry root in ſubſtance is from a ſcruple to a dram, or two. An ointment made of the freſh roots and leaves with lard, is alſo much recommended in the itch, and other cutaneous foulneſſes. The roots yield in diſtillation an eſſential oil, which concretes into white flakes, reſembling camphor in many of its properties, and ſoluble in ſpirit of wine. An extract may alſo be obtained from the dry root, both by water and ſpirit; an ounce yielding by watery 6½ drams, and by ſpirit 2½.

ELECAMPANE *wine*. See WINE.

ELECT, from *eligo*, *I chuſe*, *choſen*, in the *Scripture*, is applied to the primitive Chriſtians. In which ſenſe the *elect* are thoſe choſen and admitted to the favour and bleſſing of Chriſtianity.

ELECT, in ſome ſyſtems of *Theology*, is a term appropriate to the ſaints, or the predeſtinated. In which ſenſe the *elect* are thoſe perſons who are ſaid to be predeſtinated to glory as the end, and to ſanctification as the means. See ELECTION and PREDESTINATION, ARMINIANS, CALVINISTS, &c.

ELECT is likewiſe applied to archbiſhops, biſhops, and other officers, who are choſen, but not yet conſecrated, or actually inveſted with their office, or juriſdiction. The emperor is ſaid to be *elect*, before he is inaugurated and crowned; a lord-mayor is *elect* before his predeceſſor's mayoralty is expired, or the ſword is put in his hands.

ELECTARY, in *Pharmacy*. See ELECTUARY.

ELECTI, in *Church Hiſtory*, a ſect of heretics, who neither eat fleſh nor married. See ACEPHALI.

ELECTION, a choice made of anything, or perſon, whereby it is preferred to ſome other.

There ſeems this difference, however, between *choice* and *election*, that *election* has uſually regard to a company or community, which makes the choice; whereas choice is ſeldom uſed, but when a ſingle perſon makes it.

We ſay, the *election* of a biſhop, a member of parliament, &c. See BISHOP, PARLIAMENT, &c.

The moſt ſolemn *election* is that of a pope; which is performed by the cardinals in four different ways. The firſt by the Holy Spirit, as they call it: when the firſt cardinal who ſcrutinizes, having given his vote for any perſon, proceeds to the adoration, and proclaims him pope, as by a ſudden inſpiration of the Holy Ghoſt. In which caſe he is deemed duly *elected*, if all, or at leaſt two-thirds of the aſſembly be conſenting thereto.

The ſecond, by compromiſe, when the whole college pitches on three cardinals, to whom they give a power of nominating the pope; which power expires upon the burning out of a candle lighted on that occaſion.

The third by way of poll or ſcrutiny, which laſt is the moſt uſual; the cardinals throwing ſealed tickets, wherein their votes are written, into a chalice, or cup, placed on the altar. Two thirds of the votes are required to determine an *election* by ſcrutiny.

The fourth is by way of acceſſion; when the votes being too much divided to *elect* any body, ſome of the cardinals deſiſt from their firſt ſuffrage, and accede, that is, give their voices to him, who has already the majority by ſcrutiny.

The way of acceſſion, however, is always added to the ſcrutiny; it being the conſtant practice for all the cardinals to give their voices, after the laſt ſcrutiny, to him whom they find to have the plurality already. So that all *elections* of popes are with the unanimous conſent of all the cardinals. See CARDINALS, CONCLAVE, and POPE.

ELECTION *of numbers, or quantities*, in *Arithmetic* and *Algebra*, denotes the different method of taking any numbers or quantities given, either ſeparately, or in pairs, &c. or it is the ſum of all the combinations that can be made with a different number of quantities, in each ſet of combinations, out of any number of quantities propoſed. Thus, the *election* of 3 quantities *a*, *b*, *c*, is 7; *a*, *b*, *c*, *ab*, *ac*, *bc*, *abc*; of 4 quantities 15; and if N repreſent the number of quantities given, $2^N - 1$ is equal to the number of *elections* required: but as the ſu-

gle quantities are equal in number to the given quantities, the number of proper *elections* will be $2^N - N - 1$.

See COMBINATION.

ELECTION *of a clerk of ſtatutes merchant*, in *Law*, a writ that lies for the choice of a clerk aſſigned to take ſtatutes merchant. It is granted out of chancery, on ſuggeſtion that the clerk, formerly aſſigned, is gone to dwell at ſome other place, or is under an impediment to attend the duty of his office, or that he has not land ſufficient to anſwer his tranſgreſſions, if he ſhould act amiſs. Fitz-Herb. Nat. Brev. 164.

ELECTION *of eccleſiaſtical perſons*. *Election* for the dignities of the church ought to be free, according to the ſtat. 9 Ed. II. cap. 14. If any perſons, that have a voice in *election*, take any reward for an *election* in any church, college, ſchool, &c. the *election* ſhall be void. And if any perſons of ſuch ſocieties reſign their places to others for reward, they incur a forfeiture of double the ſum; and both the parties are rendered incapable of the place. Stat. 31 Eliz. cap. 6.

ELECTION *of a wardour of the foreſt, electione viridiariorum foreſtæ*) in *Law*, a writ that lies for the choice of a wardour, where any of the verderours of the foreſt are dead, or removed from their offices. This writ is directed to the ſheriff, and the verderour is to be elected by the freeholders of the county, in the ſame manner as coroners. New Nat. Brev. 166.

ELECTION is alſo the ſtate of a perſon who is left to his own free will, to take or do either one thing, or another, which he pleaſes. See LIBERTY.

ELECTION, in *Theology*, ſignifies the choice which God, of his good pleaſure, makes of angels or men, for the objects of mercy and grace.

The *election* of the Jews, was the choice God made of that people to be more immediately attached to his worſhip and ſervice, and for the Meſſiah to be born of them. And thus particular nations were *elected* to the participation of the outward bleſſings of Chriſtianity.

ELECTION alſo, in the language of ſome divines, ſignifies a PREDESTINATION to grace and glory, and ſometimes to glory only. And it has been enjoined as an article of faith, that predeſtination to grace is gratuitous, merely and ſimply ſo; *gratia, quia gratis data*. But the divines are much divided as to the point, whether *election* to glory be gratuitous, or whether it ſuppoſes obedience and good works, i. e. whether it be before, or after, the proviſion of our obedience. See GRACE and REPROBATION.

ELECTION is alſo uſed for a part of *Pharmacy*; being that which teaches how to chuſe the medicinal ſimples, drugs, &c. and to diſtinguiſh the good from the bad.

Some diſtinguiſh a general *election*, which gives the rules and marks for all medicines in general; and a particular one for each medicine in particular. Pomet, in his Hiſtory of Drugs, gives very good rules for this *election*.

ELECTIVE, ſomething that is done, or paſſes, by election. See ELECTOR.

Some benefices are *elective*, others collative. Municipal offices in England are generally *elective*; in Spain, venal. Poland is an *elective* kingdom. All prelatures in France are *elective*, ſince the Concordat.

ELECTIVE *attraction*, in *Chemiſtry*. See AFFINITY.

ELECTOR, a perſon who has a right to *elect*, or chooſe another to an office, honour, &c.

The word is formed of the Latin *eligere, to chooſe*.

We ſay the *electors* of a burgeſs, a knight of the ſhire, a grand maſter of an order, &c.

ELECTOR is particularly, and by way of eminence, applied to certain princes of Germany, in whom lies the right of electing the emperor, being all ſovereigns, and the principal members of the empire.

The origin of *electors* is not well known: ſome refer it to an edict of Otho III. confirmed by Gregory V. about the year 996. But this opinion is contradicted by the whole tenor of hiſtory. From the earlieſt period in the hiſtory of Germany, the perſon who was to reign over all, was elected by the ſuffrage of all. Thus, Conrad I. was elected either by all the princes and chief men, or by the whole nation; in 1204. Conrad II. was elected by all the chief men, and his election was approved and confirmed by the people; and at the election of Lotharius II. in 1125, forty thouſand perſons of all ranks were preſent, and he was named by the chief men, whoſe nomination was approved by the people. Others refer it to Frederic II. who died in 1250.

The firſt author who mentions the ſeven electors is Martinus Polonus, in this reign; and this reſtrictive privilege was probably obtained by degrees. The princes of greater authority were firſt allowed to name the perſon whom they wiſhed to be choſen emperor, and the people retained the right of approving or diſapproving the nomination; and when they had ſecured the right of voting firſt, or of *præcaution*, as it was called, it became needleſs for the inferior eccleſiaſtics or barons to attend, merely to confirm their choice; more eſpecially as their attendance would become troubleſome and expenſive. Beſides, the aſſumed privilege of the ſeven electors, who poſſeſſed the moſt extenſive territories, was ſtrongly ſupported by their numerous dependents and allies; and they were conſidered as the repreſentatives of all the orders which compoſed the higheſt claſs of German nobility. See Robertſon's Hiſt. chap. v. vol. i. p. 456, &c. 8vo. edit.

Others have aſcribed the origin of *electors* to Ralph of Hapſburgh, founder of the Houſe of Auſtria, in the year 1280.

It appears from the above account that their number was unſettled, at leaſt till the time of Frederic II. in the thirteenth century. The golden bull, publiſhed by Charles IV. in 1356, fixed the number of *electors* to ſeven; three of them eccleſiaſtics, viz. the archbiſhops of Mentz, Treves, and Cologn; and four ſeculars, viz. the king of Bohemia, the count palatine of the Rhine, the duke of Saxony, and the marquis of Brandenburgh. By the treaty of Munſter, in 1648, this order was changed; the duke of Bavaria being put in the place of the count Palatine, and an eighth electorate erected for the count Palatine.

In the year 1692, a ninth electorate was created by the emperor Leopold, in favour of Erneſt duke of Hanover, under the title of elector of Brunſwic. Some oppoſition was made to this election; and the princes of Germany ſtood out for ſome time, and refuſed to acknowledge it. But they afterwards acquieſced in it, and it has been ſince recognized by all the foreign princes. The king of France did it at laſt by the treaty of Raſtadt.

The *electors* have not only the power of chuſing the emperor, but they have actually exerciſed that of depoſing him. Thus they depoſed Adolphus of Naſſau in 1298, and Wenceſlaus in 1401.

The ſeveral functions of the *electors* are as follow: the *elector* of Mentz is chancellor of Germany; he convokes the ſtates, and gives his vote before any of the reſt. The *elector* of Cologne is grand chancellor of Italy, and conſecrates the emperor. The *elector* of Treves is grand chancellor of the Gauls, and confers the impoſition of hands on the emperor. The count palatine of the Rhine is grand maſter of the imperial palace, and preſents the emperor with a globe at his coronation. The marquis of Brandenburgh is grand chamberlain, and puts the ring on the emperor's finger. The duke of Saxony is grand marſhal, and gives the ſword to the emperor. The king of Bohemia, who was anciently only duke, is grand butler, and puts Charlemagne's crown on the emperor's head. Laſtly, the *elector* of Hanover, now king of Great Britain, is arch-treaſurer; though firſt erected under the title of ſtandard-bearer of the empire.

The *electoral* prince is the eldeſt ſon of an *elector*, and the preſumptive heir of his dignity.

Electors are always addreſſed under the title of *electoral highneſſes*.

The *electoral* college, conſiſting of all the *electors* of the empire, is the moſt illuſtrious and auguſt body in Europe. See DIET.

ELECTORS *of members of parliament*. See BURGESS, and PARLIAMENT.

ELECTORAL *crown*, or *coronet*. See CROWN.

ELECTORATE, the dignity of an elector, with the territory, or dominions, to which that quality is annexed. See ELECTOR.

Though the cuſtom ordinarily be, in Germany, for the ſons of princes to ſhare their fathers lands and territories among them, thoſe whereto the *electorate* is annexed, are not uſed to be divided, but paſs entire to the eldeſt ſon who ſucceeds to the *electorate*.

ELECTRIC, *derived from* ἤλεκτρον, *amber*, in *Phyſics*, is a term applied to thoſe ſubſtances, in which the *electric* fluid is capable of being excited, and accumulated, without tranſmitting it, and therefore called *non-conductors*, in oppoſition to CONDUCTORS, under which article the reaſon of the terms, and the difference between *electric* and conducting ſubſtances, are particularly explained. Theſe are alſo called *electrics per ſe*, and original *electrics*. To this claſs belong glaſs, and all vitrifications, even of metals, all precious ſtones, of which the moſt tranſparent are the beſt; all reſins, and reſinous compoſitions; amber, ſulphur, baked wood, all bituminous ſubſtances, wax, ſilk, cotton, all dry animal ſubſtances, as feathers, wool, hairs, &c. paper, white ſugar, and ſugar-candy, air; the vapour of water, when examined in a degree of heat, in which it is capable of condenſing into water, and alſo that of quickſilver, as Dr. Prieſtley has very lately found (Obſ. on Air, &c. 1779. p. 426); ice frozen to the

13th

13th degree below 0 of Fahrenheit's scale, and produced from diſtilled water, as has been lately diſcovered by Mr. Achard of Berlin; oils, CHOCOLATE, calces of metals and ſemi-metals, the aſhes of animal and vegetable ſubſtances, the ruſt of metals, all dry vegetable ſubſtances, and all hard ſtones, of which the beſt are the hardeſt. Subſtances of this kind are capable of being excited, ſo as to exhibit the electrical appearances of attracting and repelling light bodies, emitting a ſpark of light attended with a ſnapping noiſe, and yielding a current of air, the ſenſation of which reſembles that of a ſpider's web drawn over the face, or any part of the body preſented to it, and a ſmell like that of phoſphorus, either by friction, or by heating and cooling, or by melting, and pouring one melted ſubſtance into another. The firſt is the moſt uſual method of exciting *electrics*; the effect of the ſecond was firſt obſerved with regard to the TOURMALIN, and has been ſince found to extend to many other ſimilar ſubſtances; and ſeveral particular circumſtances have been found to attend the operation of melting ſulphur, wax, &c. according to the nature of the veſſels in which they are diſſolved, and of the ſubſtances with which they are in contact, when left to cool.

Whenever an *electric* is excited by friction, it is neceſſary that the ſubſtance with which it is rubbed, called the *rubber*, ſhould communicate with the earth or with bodies abounding with electricity, by means of good conductors; for if the rubber be inſulated, i. e. if its communication with the earth be intercepted by *electrics*, the effect of friction will be inconſiderable, and the electrical power excited by it be very weak. An *electric* will not part with the power excited by friction, by bringing other *electric* ſubſtances into contact with it; and, therefore, a glaſs tube, or globe, ſurrounded by the air, which is an *electric*, retains its virtue for ſome time; but as the air is never a perfect *electric*, it will gradually loſe it, by communication to the moiſture, and other conducting particles, that float in this element. An inſulated conductor may alſo receive the electrical power, communicated to it by the approach of excited *electrics*, will then exhibit ſimilar appearances, and retain it in the ſame manner. But if any other conductor, communicating with the earth, be brought into contact with it, the electrical power will be conveyed away at once; whereas an excited *electric*, being itſelf a non-conductor, will loſe only part of the power which it poſſeſſes from that portion of the ſurface, to which the conductor is immediately preſented, and thus the whole is exhauſted by degrees; and, therefore, the ſpark of fire is not ſo denſe, nor the exploſion ſo loud from excited, as from communicated electricity.

No *electric* can be excited, without producing electrical appearances in the ſubſtances by which it is excited, provided that ſubſtance be inſulated; but the electrical powers of the excited *electric*, and of the inſulated rubber, are directly the reverſe of each other, and may be eaſily diſtinguiſhed, by their exhibiting oppoſite effects. Thus, if a ſmall ball of cork be ſuſpended by a ſilken thread, and preſented to the *electric*, it will be firſt attracted, and then repelled; but in this ſtate of repulſion from the *electric*, it will be more violently attracted by the rubber, than by any other conducting ſubſtance, and *vice verſa*. And if two ſuch inſulated balls of cork be preſented either to the *electric* or rubber ſeparately, they will repel each other; but if one of theſe balls be preſented to the *electric*, and the other to the rubber, and they be then brought within a ſufficient diſtance, they will mutually attract each other, and their electricity will be diſcharged: they have evidently the ſame effect of counterbalancing and deſtroying each other, as poſitive and negative quantities in algebra; and it has been obſerved, that two pieces of glaſs, or ſilk, poſſeſſed of theſe contrary electricities, will cohere together, and require a conſiderable force to ſeparate them. Beſides, theſe oppoſite powers may be diſtinguiſhed by preſenting any pointed conductor to the *electric*, ſuppoſed to be glaſs, and to the rubber of the common leather kind, in the dark; the light iſſuing from the *electric* to the point will appear like a ſtar upon it; but the light iſſuing from the point to the rubber will be a tufted pencil or brush, diverging from the point towards the rubber. See BRUSH, *Luminous* CONDUCTOR, and STAR.

We may alſo add, that a current of air may be perceived paſſing from theſe points, in both caſes, in oppoſite directions.

Moſt *electrics* may be made to acquire either of theſe electricities at pleaſure, by uſing proper rubbers; but as the former of them was firſt diſcovered by rubbing glaſs, it was called the *vitreous*, and the latter, produced by reſinous ſubſtances, as amber, ſealing-wax, ſulphur, &c. was called the *reſinous* electricity. However, electricians, afterwards concluding that excited glaſs acquired more than its natural quantity of the *electric* fluid by friction, and that excited wax or ſulphur, or the inſulated rubber, loſt part of it, called the former *poſitive*, and the latter *negative* electricity; terms which are now generally uſed, and juſtified by the principal phenomena of this ſcience. See *Theory of* ELECTRICITY.

The following table will ſhew what kind of electricity is excited in different bodies, when rubbed with different ſubſtances.

Back of a cat	Poſitive	Every ſubſtance with which it has been hitherto tried.
Smooth glaſs	Poſitive	Every ſubſtance hitherto tried, except the back of a cat.
Rough glaſs	Poſitive	Dry oiled ſilk, ſulphur, metals.
	Negative	Woollen cloth, quills, wood, paper, ſealing-wax, white wax, the human hand.
Tourmalin	Poſitive	Amber, air.
	Negative	Diamond, the human hand.
Hare's ſkin	Poſitive	Metals, ſilk, load-ſtone, leather, hand, paper, baked wood.
	Negative	Other fine furs.
White ſilk	Poſitive	Black ſilk, metals, black cloth.
	Negative	Paper, hand, hairs, weaſel's ſkin.
Black ſilk	Poſitive	Sealing-wax.
	Negative	Hare's, weaſel's, and ferret's ſkin, load-ſtone, braſs, ſilver, iron, hand.
Sealing-wax	Poſitive	Metals.
	Negative	Hare's, weaſel's, and ferret's ſkin, hand, leather, woollen cloth, paper.
Baked wood	Poſitive	Silk.
	Negative	Flannel.

Cavallo's Electricity, p. 27.

See a larger catalogue of this kind, in which the rubbers were woollen garments, and ſilk, by Mr. Henly, in the Phil. Tranſ. vol. lxvii. part i. p. 122, &c.

It may be obſerved in general, that when different ſubſtances are rubbed together, the ſubſtance, whoſe electrical power is the ſtrongeſt, acquires the poſitive, and the other the negative electricity; and when two bodies, differing in the ſmoothneſs or roughneſs of their ſurfaces, are rubbed together, the ſmoother, which requires the leaſt friction, acquires the poſitive; and the rougheſt, the negative electricity. We may alſo obſerve, that, if an inſulated conductor be brought within the atmoſphere, or ſphere of action, of an excited *electric*, or an electrical body, it will acquire on the ſide exhibited to the *electric*, an electricity oppoſite to that of the electrified body; which increaſes the nearer it approaches, till at laſt the conductor receives a ſpark from the *electric*, and the equilibrium is reſtored. But if the conductor be inſulated, both its ſides will in the ſucceſs appear to be electrified; that next to the *electric* acquiring an electricity oppoſite to that of the *electric* itſelf, and the remoter ſide poſſeſſing the ſame kind of electricity with the *electric*; and when the diſcharge is made, the electrical power of the inſulated conductor, and of the *electric*, are of the ſame kind.

If an *electric* be brought near to an electrified body, the circumſtances will be the ſame during the approach of one to the other; however, when the *electric* has received a ſmall quantity of electricity from the electrified body, it will ſtill, in ſome caſes, exhibit ſtrong electricities on different ſides, and repeated changes may ſometimes be obſerved from poſitive to negative electricity in the ſame *electric*; a phenomenon, which is explained by the non-conducting quality of an *electric*, and the diſpoſition which bodies have to acquire an electricity contrary to that of another contiguous electrified body. See *Electrical* ATMOSPHERE.

ELECTRIC, *charging and coating of.* See CHARGE, and COATING.

ELECTRICAL *air thermometer*, is an inſtrument contrived by Mr. Kinnerſly of Philadelphia, and uſed in determining the effects of the *electrical* exploſion upon air. This inſtrument conſiſts of a glaſs tube AB (*Tab.* II. *Electricity, fig.* 15.) about eleven inches long, and one inch in diameter, cloſed, air-tight, with braſs caps. C and D, which may be ſcrewed on or taken off at pleaſure; and of a ſmall glaſs tube, K, open at both ends, cemented into the braſs tube, L, which ſcrews into the upper part, C. The upper end of this tube has a braſs ferrule with an air-hole, *a*, and the lower end is immerſed in coloured water at the bottom of the tube AB. Within this tube,

AB,

A B, are fixed two wires, F and G; the wire F defcends from a brafs cap at the upper end, and the wire G paſſes through the lower cap into the pedeſtal E, to which the veſſel, A B, is fixed by means of a male ſcrew, D, that goes into a brafs nut at E; and this wire may be raiſed or lowered at pleaſure, by means of a male ſcrew annexed to it, ſo as to produce a diſcharge from F to G. The wire, K, is a ſmall round ſcrew, encompaſſing the tube K L, and when air is blown into this tube, ſo as to raiſe the coloured water up to c, the gage-wire, K, is brought down to the top of the column, and the *thermometer* is ready for uſe. It is evident from the conſtruction of this inſtrument, that, when the air within the tube A B is rarefied, the water will riſe in the ſmall tube, and the degree of its aſcent will meaſure the degree of rarefaction. When the wires F and G are in contact, a large charge of electricity, from above thirty ſquare feet of coated glaſs, produces no rarefaction in the air; the water in the ſmall tube not being at all moved from the gage-wire; and therefore the paſſage of the *electrical* fluid through conductors ſufficiently large, neither rarefies nor diſplaces the air about them. But when the wires are about two inches aſunder, the ſame charge raiſes the water to the top of the ſmall tube; and a charge from a glaſs jar, containing about five gallons and a half, raiſes it to d; which ſudden riſe is owing to a quantity of air actually diſplaced by the *electrical* flaſh. When the air re-acteth, the water in the tube ſubſides, till it is in equilibrio with the rarefied air; and then gradually deſcends, as the air cools, and ſettles at its former height. By carefully obſerving at what height above the gage-wire K, the deſcending column of water firſt ſtopped, Mr. Kinnerſley diſcovered the degree of rarefaction produced by the *electrical* exploſion. Franklin's Letters, &c. p. 389, &c. 4to. 1769.

ELECTRICAL *apparatus* conſiſts of glaſs tubes, about three feet long, and an inch and a half in diameter, one of which ſhould be cloſed at one end, and furniſhed at the other end with a brafs cap, and ſtop cock, in order to rarefy, or condenſe, the incloſed air; ſticks of ſealing-wax, or tubes of rough glaſs, or glaſs tubes covered with ſealing wax, or cylinders of baked wood, for producing the negative electricity: with proper rubbers, as black oiled ſilk, with AMALGAM upon it for the former, and ſoft, new flannel, or hare ſkins, or cat's ſkins, tanned with the hair on, for the latter; coated jars, or plates of glaſs, either ſingle, or combined in a battery, for accumulating electricity; metal rods, as diſchargers; an electrical machine; electrometers, and inſulating ſtools, ſupported by pillars of glaſs, covered with ſealing-wax, or baked wood, varniſhed or boiled in linſeed oil. See theſe more particularly deſcribed under the articles *Electrical* BATTERY, CONDUCTORS, DISCHARGER, ELECTRICAL *Machine*, ELECTROMETER, &c.

Signior Beccaria contrived a ſubſtitute for glaſs, which is an expenſive article in the apparatus of an electrician, by mixing equal quantities of very pure colophonium, and finely pulverized marble, well dried, melting the mixture, and then ſpreading it on a piece of tinfoil, two or three inches beyond the edge of it, about one tenth of an inch thick; over this he laid another piece of tinfoil within about two inches of the edge of the mixture; and this coated plate ſerved him inſtead of a plate of glaſs, poſſeſſed a greater power, retained it longer, was leſs liable to break, and eaſily repaired.

ELECTRICAL *atmoſphere*. See ATMOSPHERE.

ELECTRICAL *attraction and repulſion*. See *Experiments and Phenomena in* ELECTRICITY and ELECTRICK.

ELECTRICAL *balls*. See BALLS and ELECTROMETER.

ELECTRICAL *battery*. See BATTERY, where the method of conſtructing a battery is deſcribed.

In caſes which require a great force of electricity, batteries are commonly uſed; but experiments of this kind ſhould be conducted with great care and caution. Metalline wires of a ſmall diameter may be made red-hot and melted by the exploſion of a *battery*; and the red-hot particles of the metal are ſcattered by the exploſion in all directions; but if the force be very great, the wire will be entirely diſperſed. If the wire be melted on a piece of glaſs, the glaſs will be marked by the exploſion with all the priſmatic colours; and a force which is juſt ſufficient to rendet a wire, ſtretched by weights, red-hot, will conſiderably lengthen it. A ſlender wire, incloſed in a glaſs tube, about a quarter of an inch in diameter, will be reduced, by a moderate diſcharge of a *battery* through it, into globules of different ſizes, which may be collected from the inner ſurface of the glaſs tube; they will be found hollow, and to be little elſe than the *metallic oxida* of the metal. Mr. Henly, and others, have obſerved, that in melting wires of ſome inches in length, the red heat begins at the end in contact with the diſcharging rod, or with the poſitive ſide of the *battery*, and proceeds gradually towards the coating of the *battery*, plainly evincing the direction of the electrical matter in the diſcharge. The conducting power of metals correſponding to the eaſe with which they are melted, the ſame ingenious electrician endeavoured to aſcertain this, by cauſing an exploſion to paſs through metal wires of different kinds, but of the ſame diameter, but he was not ſatisfied with the reſult of his trials.

Dr. Prieſtley infers, from ſome experiments on the conducting power of different metals, that the order in which they are to be ranked, with reſpect to the power of electricity to melt them, is the following; viz. iron, braſs, copper, ſilver, and gold; however, farther experiments are ſtill wanting for the abſolute deciſion of this queſtion. In comparing different exploſions by their power to melt wires, it muſt be obſerved, that, in wires of ſome thickneſs, the forces that melt them will be in the proportion of their lengths; and in wires of the ſame length, in the proportion of the ſquares of their diameters. Mr. Henly, having obtained ſome grains of purified platina, which had received the utmoſt force of chemical fire, laid them in contact with each other on a ſine drawn with a blunt-ended wire over the ſurface of a plate of white wax, about the length of half an inch, and at each end of the line of platina, and in contact with it, he placed a thick wire, with its ends nicely rounded off, and made perfectly ſmooth; and having covered the platina with a piece of thick plate-glaſs, and diſcharged through it three jars, containing fifteen ſquare feet of coated ſurface, he fuſed it into ſeveral beautiful ſpherules. Mr. Nairne has ſince repeated the experiment with equal ſucceſs. Phil. Tranſ. vol. lxii. part ii. art. 41. p. 412. 416, &c. Prieſtley's Hiſt. of Electricity, vol. ii. p. 370.

One of the moſt curious experiments in this department of electricity is that of making coloured rings on the ſurfaces of metal, by the electrical exploſion. See COLOURS, and FAIRY *Circles*.

We have already ſhewn how earthquakes may be imitated by the exploſion of an *electrical battery*. See EARTHQUAKE.

The effects of the lateral force of electrical exploſions firſt taken notice of by Dr. Prieſtley, are beſt obſerved in the diſcharge of a *battery*; though they may be alſo ſeen in the diſcharge of a ſingle jar.

If pieces of cork, powder of any kind, or any light bodies, be placed near the exploſion of a jar, or *battery*, they will be moved out of their places at the inſtant of the diſcharge, in all directions from the centre of the exploſion. A remarkable phenomenon of this kind happens in firing gun-powder by *electrical* exploſions; for, let the powder be ever ſo cloſely confined, if the exploſion is made in the centre of it, a part of it only will be fired, and the reſt will be diſperſed with great violence; and the fragments of a melted wire, placed in the midſt of the powder, will fly about to a great diſtance from the place of exploſion. The greater the force of the exploſion, ſo much the greater will be the diſtance to which light bodies will be removed; and therefore it is no wonder that very heavy bodies ſhould be moved to conſiderable diſtances by ſtrong flaſhes of lightning. Dr. Prieſtley apprehends, that this lateral force is produced by the exploſion of the air from the place where the exploſion is made; for the electrical matter makes a vacuum of air in its paſſage; and this air being ſuddenly diſplaced gives a commotion to all the bodies that happen to be near it. This lateral exploſion may be rendered viſible, by placing a charged jar on a table, and bringing one end of an inſulated metallic rod contiguous to its outſide coating, and placing a body of about ſix or ſeven feet in length, and a few inches broad, within about half an inch of its other end. Then, if a chain be put upon the table, with one end about an inch and a half diſtant from the coating of the jar, and one knob of the diſcharging rod be applied to the other end of the chain, and the other knob to the wire of the jar, ſo as to make a diſcharge, a ſtrong ſpark will be ſeen between the inſulated rod, which communicates with the coating of the jar, and the body near its extremity; which ſpark does not alter the *electrical* ſtate of that body; and therefore it is imagined, that this lateral ſtroke flies from the coating of the jar, and inſtantaneouſly returns to it. This phenomenon may probably be owing to the interruption in the circuit; for in proportion to the interruption will be the degree of the lateral exploſion. Hiſt. Electr. vol. ii. p. 336. 8vo. 1775. Phil. Tranſ. vol. lix. p. 57.

Dr. Prieſtley tried the effects of the exploſion of a large battery on ſome of the larger animals, as on a cat and dog, with a deſign of obſerving in what manner the animal ſyſtem is affected by the *electrical* ſhock. He found that convulſions attended the ſtroke, which were followed

by a convulsive respiration, and a rattling in the throat, with other circumstances, for which we must refer to his History, &c. vol. ii. p. 253. Bro. 1775.

It has been doubted whether, when small animals are killed by the *electrical* shock, any of the blood-vessels are ruptured; but Mr. Henly informs the editor, that, on giving the shock of a very large *battery* to a full grown duck, which was instantly killed, the animal bled freely at the mouth, which fully ascertained that fact. The duck was struck by the conductor on the crown of the head, and the charge made to pass through its legs.

We shall close this article with hinting at two circumstances, which should be attended to by those who make experiments with *electrical batteries*. The jars of a large *battery* are liable to be broken at the time of their discharge; and partly shatter'd if it be constructed of the thinner glass, which is capable of receiving a greater charge than the thicker. In order to avoid this inconvenience, Mr. Nairne never discharges a *battery* through a good conductor, unless the circuit be at least five feet long; but the length of the circuit, though it may preserve the *battery*, proportionably weakens the force of the shock. Care should also be taken not to touch the wires of a *battery* with the hand, nor even that of a single jar, after the discharge; before the discharging rod be repeatedly applied to its sides; as there generally remains a *residuum* of the charge, which is sometimes very considerable. This *residuum* is occasioned by the electricity, which, whilst the jar, or *battery*, is charging, spreads itself over the uncoated surface of the glass, near the coating; this will not be discharged at first, but gradually returns to the coating after the first discharge.

ELECTRICAL *kite* was contrived by Dr. Franklin, to verify his hypothesis of the identity of electricity and lightning. It consisted of a large, thin silk handkerchief, extended and fastened at the four corners to two slight strips of cedar, and accommodated with a tail, loop, and string, so as to rise in the air like those of paper. To the top of the upright stick of the cross a very sharp pointed wire was fixed, rising a foot or more above the wood; and to the end of the twine, next the hand, a silk ribband was tied. From a key suspended at the union of the twine and silk, when the kite is raised during a thunder storm, a phial may be charged, and electric fire collected, as is usually done by means of a rubbed glass tube, or globe. Phil. Trans. vol. xlvii. p. 565. or Franklin's Letters, p. 111, 112.

Kites made of paper, covered with varnish, or with well boiled linseed oil, in order to preserve them from the rain, with a flick and cane bow, like those of schoolboys, will answer the purpose extremely well, and are very useful in determining the electricity of the atmosphere. See CONDUCTOR.

ELECTRICAL *machine* is a part of the *electrical* apparatus, contrived for collecting a greater quantity of electricity, and exhibiting its effects in a more sensible manner than it was possible to do in any other way. The parts of which it consists are the electric, the moving engine, the rubber, and the prime conductor. The electric now commonly used is smooth glass; though in the earliest state of this science, before the method of insulating the rubber, and thereby of producing negative electricity, was introduced, other substances, as sulphur, rough glass or sealing-wax, were used for this purpose. It is not yet absolutely determined what kind of glass is the most proper; the best flint glass is generally used. Dr. Priestley suggests, that common bottle metal, on account of its great hardness, and exquisite polish, is fittest for the purpose of excitation. Thinner glass seems to be preferable to that which is thicker; but the workmen should be cautioned not to let the glass suddenly cool, which renders it liable to break in electrical operations. The common form of the electric is either that of a globe or of a cylinder. Each figure has its advantages, and its inconveniences. In favour of cylinders, it is alleged, that more of their surface may be touched with the rubber; and, on the other hand, globes may more easily be blown true, so as to press the rubber equally; and they may also be made larger in diameter, whereby their axis, if they have any, is farther from the excited surface, which is absolutely necessary to prevent the dissipation of the electric fire. Globes are, on this account, made with one neck, cemented to a strong brass cap, in order to adapt them to a proper frame; and Dr. Priestley advises to preserve a communication between the external air, and the air within the globe, by means of a hole in this cap, so that both may be always of the same density. The most convenient size is from nine to twelve inches in diameter. Cylinders are also made with two necks, without any axis, and their common size is from four inches diameter, and eight inches long, to twelve inches diameter, and two feet long.

Some have recommended an internal coating of some electric substance, as resin, turpentine, &c. in order to increase the *electrical* power of the glass. The best composition for this purpose is prepared by boiling four parts of Venice turpentine, one part of resin, and one part of bees-wax, for about two hours, over a gentle fire, and stirring it often, with the addition of one fourth part of vermilion; which is afterwards left to cool. This mixture may be used, by breaking a sufficient quantity of it into small pieces, putting it into the glass, and holding the glass near the fire till it is melted, and by continually turning the glass, equally spread over its surface in a coat of about the thickness of a six-pence. Phil. Trans. vol. lviii. p. 186.

There have been various contrivances for giving motion to the electric of a *machine*. Some have used multiplying wheels, which are easily turned by a winch. The common method is to fix a wheel, grooved round its circumference on the outside of the frame of the *machine*, which may be turned by a winch; and on the neck of the globe, or cylinder, to fix a pulley, whose diameter is about a third or fourth part of the diameter of the wheel; and a string of worsted, or a leathern strap, is put over both the wheel and the pulley; so that by turning the winch the electric may make three or four revolutions for one revolution of the wheel. As the string relaxes by use, it may be proper to make the wheel moveable from the frame, so that it may be fixed by means of a screw at a proper distance, for a sufficient tension of the string; or the pulley may have several grooves, forming circumferences of different diameters for this purpose. Instead of the pulley and string, some have used a wheel and pinion, or a wheel and endless screw, which render the *machine* more neat and compact; though this construction is not without its inconveniences, which are not so easily remedied as those of the other.

The next principal part of a *machine* is the rubber, which excites the electric. Rubbers were formerly made of red bafil fains, ftuffed with hair, wool, flax, or bran; but Dr. Nooth has lately introduced filk cushions, ftuffed with hair, over which a piece of leather is to be laid, rubbed with amalgam, which are preferable to the others. If the rubber is fixed on a metal plate, the plate should be free from all edges and points, and covered with filk; it fhould reft on a fpring, fo that it may be made to fuit any inequalities in the furface of the glafs; which fpring may, by means of a fcrew, be made to preſs more or leſs againſt the glafs at pleaſure. The rubber fhould alſo be inſulated in any way that may beſt ſuit the conſtruction of the *machine*, and the diſpoſition of the electric; and a chain or wire may be eaſily ſuſpended from it, to communicate with the floor, whenever the inſulation is not neceſſary; and thus poſitive and negative electricity may be produced at pleaſure.

The prime conductor, which is a neceſſary appendage to the *electrical machine*, in order to collect the electricity from the electric, and the method of inſulating it, have been already deſcribed. See *Prime* CONDUCTOR.

To this general account of *electrical machines*, we ſhall ſubjoin a deſcription of ſome of the principal now in uſe, illuſtrated by correſponding figures. We ſhall premiſe, however, a reference to *Tab.* II. *Electricity, fig.* 36. which repreſents Dr. Watſon's machine, with a contrivance for charging four large globes at once, and of uniting the power of them all; though no ſuch *machines* are now conſtructed. Such *machines*, furniſhed with ſuitable batteries, might be employed to very important purpoſes, and probably lead the way to many new diſcoveries in the ſcience of electricity.

The *machine*, repreſented in *fig.* 15. is the moſt compact and elegant, were it not liable to many inſuperable objections. The globe A is turned with the winch B, by means of wheel-work enclоſed in the brass box C; the rubber D is fixed to a ſpring, the preſſure of which may be adjuſted by the ſcrew F; the conductor, G H, is a braſs tube, with a round hollow ball at each end, which collects fire by the braſs piece I, fixed in the ball H. The barrel of the conductor is put into the braſs ſocket *e*, the ball G being firſt taken off; and to this ſocket is joined the braſs ſocket K, in which the upper end of the glaſs

glass tube L is fixed with cement; and the lower end is cemented into the wooden foot M; and it is thus insulated.

Machines of this kind may be screwed to a table, and used with great ease; but they admit of little variety with respect to the size, shape, or number of the electrics; and the rubber is not insulated.

The *machine* exhibited in *Tab.* III. *Electricity*, *fig.* 18. was invented by Mr. Read, mathematical instrument maker at Knightsbridge, and consists of a cylinder A, perpendicular to the horizon, and supported by a brass bow, which receives the upper end of the axis. It is moved by means of a pulley at the lower end of the axis, and a wheel B, which lies parallel to the table, and revolves four times for every single revolution of the wheel. The conductor C is furnished with points to collect the fire, and it is screwed to the wire of a coated jar D, which stands in a socket between the cylinder and the wheel. Mr. Lane's electrometer is annexed to the figure, which will be explained under the article ELECTROMETER. In this *machine* the conductor is fixed; but it admits no variety of globes or cylinders, and no insulation of the rubber.

The *electrical machine* constructed by Dr. Ingenhousz, consists of a circular glass, about nine inches, or a foot, in diameter, which turns vertically, by a branch fixed to the iron axis that passes through the middle of it, and is rubbed by four cushions, each an inch and a half, or two inches long, placed at the opposite ends of the vertical diameter. The frame is a board about a foot square, which may be fastened by an iron crank to a table, supporting two smaller upright boards parallel to one another, and fastened at top by a transverse piece; the axis of the plate rests on the middle of these boards, and to them the rubbers are fastened. The conductor is a brass tube, with two horizontal branches, extending from its extremity, and reaching within about an inch and a half of the extremity of the glass, and thus collecting the electricity from it. A *machine* of this kind was constructed about the same time by Mr. Ramsden, mathematical instrument maker in London. However ingenious the contrivance of this machine, it is liable to the inconvenience of not easily admitting the insulation of the rubbers.

This machine hath been greatly improved by Mr. Cuthberdon, at Amsterdam. He uses two plates of glass, and has contrived to insulate his rubbers in an elegant manner. In short, he hath by these means constructed some of the most powerful, and at the same time portable, and elegant machines that have yet been exhibited.

The *machine* represented in *fig.* 7. *Tab. Electricity*, was contrived by Dr. Priestley, and is excellently adapted to all the purposes which the electrician can propose. The frame consists of two boards of mahogany, *a*, *a*, parallel to one another, and about four inches asunder; the lower board may be fixed to a table by iron cranks; two upright pillars of baked wood are supported by this board, one of which, *b*, being let through the upper, is fixed immoveably to the lower board; but the other is made to slide in a groove, reaching almost the whole length of the upper board, so that it may be placed at any required distance from the other pillar, for the convenience of insulating globes, or cylinders, of different sizes; however, it is necessary only when an axis is used. In both pillars there are several holes, by means of which globes of different sizes may be mounted higher or lower, or two or more globes may be used at the same time; though it will be difficult to fix proper rubbers to them all. When a globe with one neck is used, a brass arm, with an open socket, *c*, is necessary to support the axis beyond the pulley; and this part may be put higher or lower, together with the brass socket in which the axis turns. The axis, *d*, is made to pass through the pillar *b*, so that it may be turned by a handle without the wheel. The frame being screwed to the table, may be placed nearer to, or farther from the wheel, as the length of the string in different states of the weather may require. The wheel is fixed in a frame by itself, as *e*, and thus it may have any situation with respect to the pulley, as may be most convenient; and it has several grooves for admitting more strings than one, if two or three globes, or cylinders, are used at once. The rubber, *f*, consists of a hollow piece of copper filled with horse-hair, and covered with a buff skin; it is supported by a socket, which receives the cylindrical axis of a round plate of glass *g*, the opposite part of which is inserted into the socket of a bent steel spring *h*. These parts are easily separated, so that the rubber, or the plate of glass, serving to insulate it, may be changed at pleasure. The spring may be either slipped along the groove, or moved in the contrary direction, so as to give it every desirable position with respect to the globe or cylinder; and it is also furnished with a screw *i*, which makes it press harder or lighter, as the operator chuses. The prime conductor of this *machine* has been already described under the article *Prime* Conductor.

When positive electricity is required, a wire or chain, *n*, connects the rubber with the table or floor, and in order to obtain negative electricity, that wire is connected with another cylindrical conductor, whilst the prime conductor in the figure is connected by another wire or chain, with the table; and Dr. Priestley observes, that the negative and positive powers are equally strong. Hist. Electr. vol. ii. p. 113, &c. five.

The *machine fig.* 19 *Tab.* III. *Electricity*, was constructed by Mr. Nairne, F. R. S. an ingenious instrument maker in London, for the grand-duke of Tuscany. The glass cylinder of this *machine* is twelve inches in diameter, and the cylindrical part, exclusive of the necks, thirteen inches long; the rubber is fourteen inches long, and five broad, supported by two wooden springs, which are fixed on two glass rods lying horizontally under the cylinder, and serving to insulate the rubber; the conductor is five feet long, and twelve inches in diameter, supported on two stands, with solid glass pillars, having at the end of it a short brass rod with a ball; the ball which is represented as receiving the electrical spark from the conductor, is of brass, and fixed to the end of a brass tube, that is moveable in a hole at the top of the stand; from the bottom of the stand a chain passes along the floor, till it is in contact with the chain hanging from the back of the rubber. The spark from this conductor would sometimes fly to the distance of fourteen inches. See *Prime* Conductor. Phil. Trans. vol. lxiv. part i. p. 79.

Another *electrical machine*, which we shall describe, is that represented in *fig.* 5. *Tab. Electricity*. This is of a convenient size, and, in a small compass, possesses the advantages of most other *machines*. The frame of the *machine* consists of the board ABC, which is capable of being fastened to a table by two iron cranks. On this board are raised two strong wooden pillars, KI, and AH, which support both the cylinder and wheel. From one of the brass caps of the cylinder FF, an axis of steel proceeds, which passes quite through a hole in the pillar KI, and has, on the outer side of the pillar, a pulley, I, fixed on its square end. In the circumference of the pulley there are three or four grooves, fitting the catgut string *a b*, which goes round one of them, and round the groove of the wheel D. The other cap of the cylinder has a small cavity, which fits the cylindrical extremity of a strong screw, that proceeds from the pillar H. The wheel D, moved by the handle E, turns round a strong axis, projecting from almost the middle of the pillar KI. The rubber G is a thin quilted cushion of silk, stuffed with hair, and fastened with silken strings to a piece of wood, adapted to the surface of the cylinder; its length is about four inches less than that of the body of the cylinder, and it rubs about one fourth part of its circumference. It is terminated at its upper extremity by a piece of oiled silk, which covers almost all the upper part of the cylinder; and to the lower part a piece of leather, well rubbed with amalgam, is fastened, which, when turned over the cushion, interposes between it and the surface of the cylinder. The rubber is supported by two springs, screwed to its back, and proceeding from the wooden cap of a strong glass pillar, perpendicular to the board on which the machine rests, and made to slide, by a square wooden baile, in two grooves of this board; and thus the pillar may be fastened by a screw at any required distance from the cylinder, and the rubber made to press harder or lighter upon it. By means of this glass pillar the rubber is insulated; and when insulation is not required, a chain may be hung to it by a small hook, communicating with the leather, and falling down to the table or floor. The prime conductor of this *machine*, made of hollow brass, (*fig.* 4.) is supported by glass pillars, fixed by brass sockets in the board CC; and it receives the electric fluid through the points of the collector L, which is placed about half an inch distant from the surface of the cylinder. If the wheel D be turned by the handle E, in the direction *a b c*, and the chain remain suspended from the rubber to the floor, the conductor AB will be electrified positively; but if the chain be removed from the rubber to the prime conductor, the rubber will be electrified negatively; and another conductor, like the former, applied to the rubber, will be charged negatively to the same degree, as that was charged positively. *Machines* of this construction are made and sold by Mr. Adams, his majesty's philosophical instrument maker, &c. in Fleet-street, London. See Cavallo's Electricity, p. 154, &c.

Dr. M. Van Marum, a late German writer, has constructed a *machine*, in which gum lac, in the form of a disc

dife, is fubſtituted as an electric in the room of glaſs, and quickſilver is uſed as a rubber. He enumerates ſeveral advantages attending this conſtruction; the effect of the machine depends very little on the temperature of the air; the operation is uniform; it is more eaſily worked than machines of the common kind; it may be kept in motion by a weight, which, after being wound up to the height of twelve feet, will continue to preſerve its motion for ſix hours; a negative ſhock may be obtained from it, exactly ſimilar to the poſitive, and the conductors armed with ſteel will ſerve to convey the *electrical* power, with very little alteration, wherever it is required, without any addition of chains, wires, &c. Verhandeling over het Electriſeren, &c. or a Treatiſe concerning the Method of Electrifying, by M. Martinus Van Marum. Groningen, 1776.

ELECTRICAL *ſhock*. See LEYDEN *Phial*.

ELECTRICAL *repulſion*. See *Experiments, &c. in* ELECTRICITY.

ELECTRICAL *rubber*. See ELECTRICAL *apparatus*, and ELECTRICAL *machine*.

ELECTRICAL *ſtroke* denotes the exploſion between the oppoſite ſides of a charged *electric*; ſo called, becauſe, if the diſcharge from one to the other be made through the body of an animal, it occaſions a ſudden motion by the contraction of the muſcles through which it paſſes, and a diſagreeable ſenſation. The force of the *ſtroke* is proportioned to the quantity of coated ſurface, the thinneſs of the glaſs, and the power of the machine by which it is charged. Its velocity is almoſt inſtantaneous, as it has not been found to ſtop or be leſſ forcible by means of time in paſſing to the greateſt diſtances. Mr. Ferguſon accounts for the *ſtroke* being felt at the ſame inſtant by perſons at various diſtances, without allowing the inſtantaneous velocity of the electrical fluid, in the following manner. If a ſmall tube of any length, and open at both ends, be filled with water, and held quite flat on level ground, the water will continue motionleſs in the tube; but if a ſyringe be filled with water, and fixed in either end of the tube, and then the piſton of the ſyringe be preſſed inward, to force more water into the tube, the whole water in the tube is thereby put into motion; and at the inſtant the piſton begins to be puſhed, the water begins to run out at the other end of the tube, which is not the water that was in the ſyringe, but that which was in the tube before. This caſe, he ſays, is exactly ſimilar to that of a number of perſons feeling the *ſtroke* at once; for each perſon has his natural quantity of electric fire, which lies dormant in him, till it is put in motion by ſome outward cauſe; and at the inſtant when the contents of the charged jar are diſcharged upon the firſt perſon, the electric fire in him is put into motion, and this puts it into motion in the next to him, and ſo on through the whole connected company. He adds, that in taking ſparks with the knuckle from a prime conductor, the velocity of the ſpark is not ſo great as to elude the ſight, even through the ſmall ſpace between the prime conductor and the knuckle. See CIRCUIT.

Query. Is not this theory of Mr. Ferguſon's liable to an objection? Suppoſe a battery ſufficient to melt three feet of ſmall wire to be diſcharged through ſuch a circuit, the wire will be melted; but if the progreſs of the charge were *gradual*, beginning with the natural quantity in the wire, would the index of Mr. Henly's electrometer fall inſtantly to its ſtem upon the diſcharge, as is really the caſe? And, if the whole charge of the battery doth not paſs through the circuit in an inſtantaneous manner, we muſt ſuppoſe the wire to contain in itſelf nearly as much electric matter as the battery is charged with; but this would be a ſuppoſition too abſurd to be admitted.

It has been obſerved, that the *electrical ſhock* is weakened by being thus communicated through different perſons in contact with one another. It is, indeed, contracted in its paſſage, even through the beſt conductors; as it will prefer a ſhort paſſage through the air to a long one through the moſt perfect conductors; and if the circuit be interrupted, either by electrics, or very imperfect conductors of a moderate thickneſs, the *ſhock* will rend them in its paſſage, diſperſe them in every direction, and exhibit the appearance of a ſudden expanſion of the air about the centre of the *ſhock*. A ſtrong *ſhock* made to paſs through or over the belly of a muſcle, forces it to contract; and ſent through a ſmall animal body deprives it inſtantly of life, and haſtens putrefaction. It gives polarity to magnetic needles, reverſes their poles, and produces effects preciſely ſimilar, though inferior in degree, to thoſe of LIGHTNING.

ELECTRICAL *ſtar*. See STAR.

ELECTRICITY, or ELECTRICAL *force*, is that power or property, which was firſt obſerved in amber, the *lyncurium*, or TOURMALIN, and which ſealing-wax, glaſs, and a variety of other ſubſtances, called ELECTRICS, are now known to poſſeſs, of attracting light bodies, &c. when excited by heat or friction; and which is alſo capable of being communicated in particular circumſtances to other bodies; and the *ſcience of electricity* is that part of natural philoſophy, which propoſes to inveſtigate the nature and effects of this power, and of other ſimilar powers connected with it. For an account of the etymology of the term, and the firſt uſe and application of it, ſee AMBER. Muſchenbroeck and Æpinus have obſerved a conſiderable analogy, in a variety of particulars, between the powers of *electricity* and magneſtiſm; and they have alſo pointed out many inſtances in which they differ.

The principal phenomena in which they reſemble one another are the following: on a glaſs tube touched by an excited tube has a ſucceſſion of poſitive and negative parts, ſo a rod of iron held near a magnet will have ſeveral ſucceſſive poles. Magnets, when their oppoſite poles are laid to one another, adhere; and thus bodies poſitively and negatively electrified, when in contact, will unite to one another; the poſitive and negative ſides of glaſs influence to the attracting and repelling ends of hardened ſteel, made magnetical; the electric and magnetic fluids are moved in both with conſiderable difficulty. As there can be no condenſation of the electric fluid in glaſs without a rarefaction, there can be no condenſation, or poſitive magneſtiſm, in one end of a bar, without an exrarefaction, or negative magneſtiſm, in the other. Steel correſponds to electrics, and iron, in ſome meaſure, to conductors; ſteel does not ſo eaſily receive the magnetic virtue, but retains it more ſtrongly than iron, as electrics receive the electric fluid with greater difficulty than conductors, but do not ſo readily part with it. Electrified bodies attract and repel other bodies, in conſequence of rendering them *electrical* ſame; a magnet attracts iron, after having firſt of all made it a magnet. The leaſt piece of a tourmalin has its poſitive and negative ſides, juſt as the pieces of a broken magnet would have theirs. Theſe powers alſo differ from one another; for, although they are both excited by friction, the magnetic virtue requires a determinate mode of friction, which the electric does not. Steel rubbed with iron will excite the former, whereas an electric rubber will not excite an electric. The magnetic virtue appears in ſome caſes without friction, or the aid of the other ordinary means of exciting electrics. A moiſt air deſtroys *electricity*, without affecting magneſtiſm; the magnetic virtue is of much longer duration than the electrical. Magnetical bodies require no particular inſulation, in order to diſcover their virtue, as electrified bodies do; magneſtiſm acts only on iron, whereas *electricity* affects moſt other bodies; the magnetic virtue is much ſtronger than the electric, and yet produces neither light nor fire. The equilibrium in a magnet cannot be reſtored, by forming a communication between the oppoſite ends with iron, as it may in charged glaſs. There are no inſulators poſitively or negatively magnetical only, as there are bodies poſitively or negatively electrical only.

Signior Beccaria has alſo made a number of experiments, with a view of aſcertaining the connection between magneſtiſm and *electricity*, and explaining the effects of the former on the latter in particular circumſtances; from which he concludes in general, that the magnetic direction given to a needle by lightning and artificial *electricity*, does not depend on the direction of the electric matter in entering into the needles but on the particular poſition of the needle when the charge is ſent through it; and he is confirmed in his conjecture, that the peculiar magnetic force, obſerved in the loadſtone, is to be aſcribed to ſome ſimilar cauſe, becauſe of ſubterraneous effects of lightning, and that the natural or acquired properties of magnetic bodies are produced by an univerſal influence or circulation of the electric element, through the atmoſphere, or in the bowels of the earth. See further on this ſubject, Muſchenbroeck. Introd. ad Phil. Natural. vol. i. p. 341, &c. 4to. 1762. and Æpinus's Tentamen Theoriæ Electric. & Magnet. 1759; or for a ſhort account of Æpinus Prieſt. Hiſt. Elec. vol. ii. p. 501. Beccaria's Treatiſe on Artificial Electricity, &c. 1776.

ELECTRICITY, *hiſtory of*. The nature and compaſs of this work will allow our only mentioning ſome of the principal diſcoveries that have been made in the ſeveral periods of the progreſs of this ſcience; premiſing, in general, that there is no ſingle branch of natural knowledge that has been cultivated with greater aſſiduity and ſucceſs, or in which ſuch rapid advances have been made within fifty years paſt, as that of *electricity*.

W. Gilbert, a native of Colcheſter, and a phyſician in London, if we conſider that the ſubject was in its higheſt degree new and unknown at his time, made many conſiderable experiments [illegible], which are contained in his treatiſe De Magnete, publiſhed in the year 1600. He enlarged the liſt both of electrics, and of the bodies

on

on which electrics act: he remarked, that a dry air was moſt favourable to electrical appearances, whilſt a moiſt air almoſt annihilates the electric virtue: he alſo obſerved the conical figure aſſumed by electriſied drops of water: he conſidered electrical attraction ſeparately from repulſion, which, he apprehended, had no place in *electricity*, as a phenomenon ſimilar to the attraction of coheſion; and he imagined, that electrics were brought into contact with the bodies on which they act by their effluvia, excited by friction.

The honourable Mr. Boyle added to the catalogue of electric ſubſtances; but he thought that glaſs poſſeſſed this power in a very low degree: he found, that the *electricity* of all bodies, in which it might be excited, was increaſed by wiping and warming them before they were rubbed; that an excited electric was acted upon by other bodies as ſtrongly as it acted upon them; that diamonds, rubbed againſt any kind of fluff, emitted light in the dark; and that feathers would cling to the fingers and to other ſubſtances, after they had been attracted by electrics. He accounted for electrical attraction, by ſuppoſing a glutinous effluvium emitted from electrics, which laid hold of ſmall bodies in its way, and carried them back to the body from which it proceeded. Otto Guericke, the famous inventor of the air-pump, lived about the ſame time: this ingenious philoſopher diſcovered, by means of a globe of ſulphur, that a body once attracted by an electric was repelled, and continued in this ſtate of repulſion till it had been touched by ſome other body: he alſo obſerved the ſound and light produced by the excitation of his globe; and that bodies immerged in electric atmoſpheres are themſelves electriſied, with an *electricity* oppoſite to that of the atmoſphere. The light emitted by electrical bodies was, not long after, obſerved to much greater advantage by Dr. Wall, who aſcribes to light the electrical property which they poſſeſs; and he ſuggeſts a ſimilarity between the effects of *electricity* and lightning. Sir Iſaac Newton was not inattentive to this ſubject: he obſerved, that excited glaſs attracted light bodies on the ſide oppoſite to that on which it was rubbed; and he aſcribed the action of electric bodies to an elaſtic fluid, which freely penetrated glaſs, and the emiſſion of it to the vibratory motions of the parts of excited bodies. Mr. Haukbee, with whom commenced a new æra in the hiſtory of this ſcience, wrote in the year 1709, and firſt took notice of the great electrical power of glaſs, the light proceeding from it, though others had before obſerved the light proceeding from other electriſied ſubſtances; and the noiſe occaſioned by it, together with a variety of phenomena relating to electrical attraction and repulſion: he firſt introduced a glaſs globe into the electrical apparatus; and to the uſe of this many of his important diſcoveries were owing. After his time there was an interval of near twenty years in the progreſs of this ſcience; till Mr. Stephen Grey eſtabliſhed a new æra in the hiſtory of *electricity*. To him we owe the capital diſcovery of communicating the power of native electrics to other bodies, in which it cannot be excited, by ſupporting them on ſilken lines, hair lines, cakes of roſin, and glaſs; and a more accurate diſtinction than had hitherto obtained between electrics and non-electrics: he alſo ſhewed the effect of *electricity* on water much more obviouſly than Gilbert had done in the infancy of this ſcience. The experiments of Mr. Grey were repeated by M. du Fay, member of the Academy of Sciences at Paris, who added to the number many new experiments and diſcoveries of his own. He obſerved, that electrical operations are obſtructed by great heat as well as by a moiſt air; that all bodies, both ſolid and fluid, were capable of receiving *electricity*, when placed on warm or dry glaſs, or ſealing-wax; that thoſe bodies which were of themſelves the leaſt electric had the greateſt degree of *electricity* communicated to them by the approach of the excited tube. He alſo tranſmitted the electric virtue through a diſtance of 1256 feet; and firſt obſerved the electric ſpark from a living body, ſuſpended on ſilken lines, and noted ſeveral circumſtances attending it. M. du Fay likewiſe eſtabliſhed a principle, firſt ſuggeſted by Otto Guericke, that electric bodies attract all thoſe which are not ſo, and repel them as ſoon as they are become electric, by the vicinity or contact of the electric body. He alſo inferred from other experiments, that there were two kinds of *electricity*; one of which he called the *vitreous*, belonging to glaſs, rock cryſtal, &c. and the other *reſinous*, as that of *amber*, *gum lac*, &c. diſtinguiſhed by their repelling thoſe of the ſame kind, and attracting each other. He obſerved, that communicated *electricity* had the ſame property as the excited; and that electric ſubſtances attract the more than conductors.

Mr. Grey, reſuming his experiments in 1734, ſuſpended ſeveral pieces of metal on ſilken lines, and found, that by electriſying them, they gave ſparks, which was the origin of metallic conductors: and, on this occaſion, he diſcovered a cone or pencil of electric light, ſuch as is now known to iſſue from an electrified point. From other experiments he concluded, that the electrical power ſeems to be of the ſame nature with that of thunder and lightning.

Dr. Deſaguliers ſucceeded Mr. Grey in the proſecution of this ſcience. The account of his firſt experiments is dated in 1739. To him we owe thoſe technical terms of *conductors* or *non electrics*, and *electrics per ſe*, which are explained in the courſe of this work. He firſt ranked pure air among the electrics *per ſe*, and ſuppoſed its *electricity* to be of the vitreous kind. After the year 1742, in which Dr. Deſaguliers concluded his experiments, the ſubject was taken up and purſued in Germany: the globe was now ſubſtituted for the tube, which had been uſed ever ſince the time of Haukbee, and a cuſhion was ſoon after uſed as a rubber inſtead of the hand. About this time, ſome uſed cylinders inſtead of globes; and ſome of the German electricians made uſe of more globes than one at the ſame time. By thus increaſing the electrical power, they were the firſt who ſucceeded in fetting fire to inflammable ſubſtances. This indeed was firſt done by Dr. Ludolf, in the beginning of the year 1744, who kindled, with ſparks excited by the friction of a glaſs tube, the ætherial ſpirit of Frobenius. Mr. Winkler did the ſame by a ſpark from his own finger, and kindled French brandy and other ſpirits by previouſly heating them. Mr. Gralath fired the ſmoke of a candle juſt blown out, and lighted it again; and Mr. Boze fired gun-powder, by means of its inflammable vapour. Ludolf the younger, about this time, demonſtrated, that the luminous barometer was made perfectly electrical by the motion of the quick ſilver: the electrical ſtar and electrical bells were alſo of German invention. Dr. Watſon in England made a diſtinguiſhed figure from this period in the hiſtory of *electricity*: he fired a variety of ſubſtances by the electrical ſpark; and firſt diſcovered, that they were capable of being fired by the repulſive power of *electricity*. In the year 1745, the accumulation of the electrical power in glaſs, by means of the Leyden phial, was firſt diſcovered. See LEYDEN *phial*. For the method practiſed about this time, of meaſuring the diſtance to which the electric ſhock may be conveyed, ſee *Electrical* CIRCUIT. Dr. Watſon made a very important diſcovery in this ſcience, that the glaſs tubes and globes did not contain the electric matter in themſelves, but only ſerved as *firſt-movers* or *determiners*, as he expreſſes it, of that power, which was alſo confirmed towards the end of 1746, by Mr. Wilſon, who made the ſame diſcovery, that the electric fluid did not come from the globe, but from the earth, and other non-electric bodies about the apparatus. Dr. Watſon alſo diſcovered what Dr. Franklin obſerved about the ſame time in America, and called the *plus* and *minus* in *electricity*. He likewiſe demonſtrated that the electric matter paſſed through the ſubſtance of the metal of communication, and not merely over the ſurface.

We muſt omit other experiments and concluſions drawn from them by Mr. Wilſon, Mr. Smeaton, Dr. Mills, in England; and by the Abbé Nollet, with regard to the effect of *electricity* on the evaporation of fluids, on ſolids, and on animal and other organized bodies, in France. The hiſtory of *medical* ELECTRICITY, commenced in the year 1747.

Whilſt the philoſophers of Europe were buſily employed in electrical experiments and purſuits, thoſe of America, and Dr. Franklin in particular, were equally induſtrious and no leſs ſucceſsful. His diſcoveries and obſervations in *electricity* were communicated in ſeveral letters to a friend; the firſt of which is dated in 1747, and the laſt in 1754. A ſummary of his ſyſtem will be delivered under the articles *Theory of* ELECTRICITY, LEYDEN *Phial*, and POINTS. See alſo CHARGING, CONDUCTORS, ELECTRICS, &c.

The ſimilarity between lightning and *electricity* had been ſuggeſted by ſeveral writers on this ſubject; but Dr. Franklin firſt propoſed a method of bringing the matter to the teſt of experiment, by raiſing an ELECTRICAL *kite*; and he ſucceeded in collecting electrical fire by this means from the clouds, in 1752, a month after the electricians in France had verified the ſame theory, and independently of any knowlege of what they had done: and to him we owe the practical application of this diſcovery, in ſecuring buildings from the damage of lightning, by erecting metalline CONDUCTORS. See alſo LIGHTNING.

In the ſubſequent period of the hiſtory of this ſcience, Mr. Canton in England, and ſignior Beccaria in Italy, acquired diſtinguiſhed reputation. They both diſcovered,

independently of one another, that air was capable of receiving *electricity* by communication, and of retaining it when received; and they had various contrivances for this purpose. Mr. Canton alſo, towards the latter end of the year 1753, purſued a ſeries of experiments, which prove, that the appearances of poſitive and negative *electricity*, which had hitherto been deemed eſſential and unchangeable properties of different ſubſtances, as, e. g. of glaſs and ſealing-wax, depend upon the ſurface of the electrics, and that of the rubber. This hypotheſis, verified by numerous and inconteſtible experiments, occaſioned a controverſy between Mr. Canton and Mr. Delaval, who ſtill maintained, that theſe different powers depended entirely on the ſubſtances themſelves. About this time, ſome curious experiments were performed, by four of the principal electricians of that period, viz. Mr. Canton, Dr. Franklin, Meſſrs. Wilcke and Epinus, in order to aſcertain the nature of electric atmoſpheres; the reſult of which may be ſeen under the article *Electric* ATMOSPHERE.

The theory of two electric fluids, always co-exiſtent and counteracting each other, though not abſolutely independent, was maintained by a courſe of experiments on ſilk ſtockings of different colours, communicated to the Royal Society by Mr. Symmer, in the year 1759, which were farther purſued by Mr. Cigna of Turin, who publiſhed an account of them in the Memoirs of the academy at Turin for the year 1765.

Many inſtances occur in the hiſtory of the ſcience about this period, of the aſtoniſhing force of the electric ſhock, in melting wires, and producing other ſimilar effects; but the moſt remarkable is an experiment of S. Beccaria, in which he thus revivified metals. Several experiments were alſo made by Dr. Watſon, Mr. Smeaton, Mr. Canton, &c. on the paſſage of the electric fluid through a vacuum, and its luminous appearance, and on the power which particular ſubſtances poſſeſs of retaining the light communicated to them by an electric explotion. Mr. Canton, S. Beccaria, and others, made many experiments to identify *electricity* and lightning, to aſcertain the ſtate of the atmoſphere at different times, and to explain the various phenomena of the AURORA *borealis*, *Water*-SPOUTS, HURRICANES, &c. on the principles of this ſcience.

Thoſe who are deſirous of farther information with reſpect to the hiſtory of electrical experiments and diſcoveries, may conſult the excellent work of Dr. Prieſtley, entitled, "The Hiſtory and Preſent State of *Electricity*, &c. Ed. 3. 1775." However, Dr. Prieſtley is not a mere hiſtorian: his work contains many original experiments and diſcoveries made by himſelf. He aſcertained the conducting power of CHARCOAL, and of hot glaſs; the *electricity* of fixed and inflammable air, and of oil; the difference between new and old glaſs, with reſpect to the diffuſion of *electricity* over its ſurface; the lateral exploſion in electrical diſcharges; a new method of fixing circular-coloured ſpots on the ſurfaces of metals, and the moſt probable difference between electrics and conductors; beſides a variety of other particulars, too numerous to be recited in this abſtract of the hiſtory, and yet of conſiderable importance with regard to the advancement and extenſion of the ſcience of *electricity*. We ſhall endeavour, in the courſe of this work, to do juſtice to the merits of other electricians, to whom the ſcience is under any peculiar obligations. The name of Mr. Henley often occurs in articles appropriated to this part of natural philoſophy; to him we owe ſeveral curious experiments and obſervations on the electrical and conducting quality of different ſubſtances, as CHOCOLATE, VAPOUR, &c. the reaſon of the difference between them; the fuſion of platina; the nature of the electrical fluid, and its courſe in a diſcharge; the method of eſtimating the quantity of it in electrical bodies by an electrometer; the influence of POINTS, &c. &c.

ELECTRICITY, *Experiments and Phenomena in*. It may be premiſed in general for the uſe of young electricians, who have not acceſs to other treatiſes on this ſubject, that every part of the electrical apparatus ſhould be kept clean and dry; that, when the air is dry and the weather froſty, experiments are performed with the greateſt eaſe and advantage; that very hot weather is unfavourable to electrical experiments; that when the air is damp, they ſhould be performed in a room well dried with a fire. If a glaſs tube is uſed, its power may be increaſed by a ſmall quantity of bees wax drawn over its ſurface, and the hand ſhould be kept two or three inches below the upper part of the rubber. The globe, or cylinder of a machine, ſhould be firſt wiped with a clean hot flannel, or an old ſilk handkerchief; the ſilken part of the rubber ſhould be well dried; and the leather that is ſpread over it ſhould be firſt rubbed with tallow, and then with AMALGAM. It may not be improper here to mention the uſe of Dr. Higgins's amalgam, which is attended with ſeveral advantages. 1. It excites a ſtronger *electricity*, and 2. Does not fly off from the rubber by the motion of the electric. The compoſition is four parts of mercury to one of zinc. Theſe are melted together in an iron ladle, over a ſlow fire. Put in firſt the zinc, and ſtir degrees and the mercury. It forms a hard maſs when cold, which may be warmed again when uſed; or it may be ſcraped off with a dull-edged knife, and ſpread upon the rubber, which is firſt to be prepared with a little tallow. See an account of Mr. Canton's amalgam, under the article AMALGAMATION *of Tin*.

The rubber, thus prepared, ſhould be made to communicate, when the room is very dry, with moiſt earth or water, by good conductors; and if the cylinder and rubber are in good order, the winch be turned, and no conductors communicate with the electric, the electric fluid will be felt on the knuckle held within a ſmall diſtance of it, like a current of air, attended with a ſpark and a crackling noiſe. When the machine has been uſed for ſome time, the electric will contract black ſpots from the amalgam, or ſoulneſs of the rubber, which muſt be carefully removed, or they will gradually increaſe, and prevent its excitation. An incruſtation of the ſame kind will be formed upon the rubber, by which it will be conſiderably improved; and if this be moiſtened or ſcraped, no addition of ſuch amalgam will be neceſſary. If the coated jars, which are deſigned for uſe, be warmed a little, they will better receive and retain the charge. Candles ſhould be placed at a conſiderable diſtance from the prime conductor, leſt their flames ſhould attract and diſperſe the electric fluid. The electrical operator ſhould be careful in the uſe of his machine, jars and battery, that he may ſuſtain no injury by any ſudden or unexpected diſcharge. Effectually to prevent this, we would always recommend the uſe of a diſcharging rod, with a handle of glaſs. With theſe precautions, there is no part of ſcience that will afford a greater variety of amuſing experiments than *electricity*. We ſhall ſelect the following as a ſpecimen.

1. If a ſmooth glaſs tube be excited by a proper rubber, and the knuckle be moved lengthways from one end of the tube to the other, without touching it, you will hear a continued ſnapping or crackling noiſe; and if the room be darkened, ſparks of light may be obſerved wherever the tube ſnaps; and a light may be ſeen following the hand that rubs the tube. When the tube is in good order, pencils of the electric matter will dart into the air from ſeveral parts of it ſpontaneouſly, and make a very beautiful appearance. If a rough tube be uſed with a proper rubber, the electric matter will be ſeen to ſpread upon its ſurface on the approach of the knuckle or any other conducting ſubſtance in a very agreeable manner. A large ſtick of ſealing-wax ſhews this phenomenon to great advantage.

2. If a ſmall light feather be brought near an excited tube, either of ſmooth or rough glaſs, it will be attracted, jump to the tube, and ſtick cloſe to the ſurface of it, till it be ſaturated with the electric matter, which, as it is a bad conductor, it receives ſlowly: it will then be repelled by it, and may be kept ſuſpended or driven about the room by the electrified tube for a conſiderable time, unleſs it parts with its *electricity* to ſome conducting ſubſtance; and in this ſtate of repulſion, the ſame ſide of the feather will be always preſented to the tube; becauſe, being a bad conductor, the ſuperinduced *electricity* will be forced by the action of the tube to that ſide which is fartheſt from it; and that ſide will, of courſe, be moſt repelled: the charged bottle produces the ſame effect. If one perſon holds in his hand an excited ſmooth tube, and another holds an excited rough tube, or any other electric negatively electrified, at the diſtance of about one foot and a half, a feather introduced between theſe two tubes, poſſeſſing oppoſite *electricities*, will leap alternately from one to the other; or, if a finger is held at eight or ten inches from either tube, the feather will alternately jump from the tube to the finger, and from the finger to the tube. This experiment may be varied, by turning the winch of an electrical machine with one hand, and holding the other about three or four inches from the end of the prime conductor; then, if a ſmall lock of cotton be let fall on the hand near the conductor, it will jump from the hand to the conductor, and from the conductor to the hand again, being alternately attracted and repelled, and aſſuming an oblong form, though its motion will be ſo quick, that little elſe beſides its colour can be ſeen.

3. If two feathers of cork balls be ſuſpended, one by a ſilken, and the other by a linen thread, an excited tube will attract them both, but repel only the former; and if the

the silken thread be well moistened, the feather suspended by it will be attracted, but no more repelled by the tube; the electric matter in both cases being instantly discharged by the conducting moisture and linen thread. If the small ball suspended by a silk thread of about eight inches in length, be held in the hand, about eight inches from an electrified prime conductor, whose *electricity*, either positive or negative, is not very strong, it will not be attracted; because, by being insulated, it is incapable of communicating part of its electric matter to, or receiving any from other bodies, and thus of acquiring an *electricity* opposite to that of the conductor. But if the finger, or any conducting body, be presented to that side of the ball which is farthest from the prime conductor, it will move towards the conductor, having either received or lost *electricity*, from the body presented to it; and after having touched the prime conductor, it will be repelled by it, both possessing the same kind of *electricity*, and having either more or less than their natural share of it. However, if the insulated ball be brought very near the prime conductor, or the prime conductor be strongly electrified, it will be attracted without presenting it to any conducting substance; for in this case, the natural electricity of the ball will be forced into the air, or accumulated on the side remotest from the conductor electrified positively; or the redundance in the ball will be acquired from the air, or its natural quantity will be accumulated on the side nearest to the conductor, electrified negatively. If the cork ball be suspended by a linen thread, it will be attracted at a much greater distance, because the electric fluid will easily pass to it, or from it along the thread, as the prime conductor is electrified positively or negatively.

4. To a ring of wire, at least a foot larger in diameter than the globe of the machine, tie pieces of fine linen thread, about five inches long, be tied at the distance of about two inches from each other. Let this ring be held horizontally round the globe, the conductor being first removed, and the globe turned, the threads will be attracted, and point towards the centre of the globe, resembling the spokes of a wheel: in this case, the electric fluid passes freely from the person who holds the ring to or from the globe, as it is electrified negatively or positively.

5. If a large plumy feather, as *h* (*fig.* 17. *Tab.* II. *Electricity*) be stuck into the prime conductor, and the globe be turned, its fibres will repel each other, and expand in all directions; but if any conducting substance be made to touch the prime conductor; or, if the point of a needle be brought near the feather or the conductor, it will shrink, the *electricity* being thus taken off; and if the point of the finger be held near the feather, it will cling round it, and bend to the motion of the finger round it.

6. If the conductor, in *fig.* 17, be placed, so that the points I may almost touch the globe of the machine; and Mr. Canton's ELECTROMETER, consisting of small cork or pith balls O and P annexed to the ends of a linen thread be suspended over the wire N, the threads will hang perpendicularly and parallel to one another, and the balls will touch; but if the globe be turned, the balls will be electrified, and repel each other, more or less in proportion to the degree of *electricity* communicated to the conductor. They are in this case electrified positively, or they receive more than their natural quantity of the electric fluid, which cannot be diffused in the air as fast as they receive it, and therefore they repel each other; but if the prime conductor were electrified negatively, they would then have less than their natural quantity, and the case would be still the same: no electric substance applied to the conductor can bring them together; but if the prime conductor be touched with some conducting substance uninsulated, the redundance would be carried off, or the deficiency supplied, and then the balls would immediately come together.

7. The attraction or repulsion of light electrified bodies may be beautifully represented, by suspending the brass plate X from the prime conductor, directly over the plate Y, and about three inches from it. See *fig.* 17. On the lower plate, place any light bodies, as bran, feathers, pieces of paper, or of leaf-gold, and then work the machine; upon which these light bodies will move to and fro between the plates, being first attracted by the upper plate, and then repelled; and having discharged themselves on the lower, they will be alternately attracted and repelled again. If small images, in the shape of men and women, be laid on the lower plate, the images will dance from one plate to the other in an amusing manner. If a piece of leaf gold be cut with a pretty large angle at one extremity, and a very acute one at the other, it will need no lower plate, but will hang by its larger angle at a small distance from the conductor; and by the continual waving motion of its lower extremity, have the appearance of something animated, nibbling at the conductor, and therefore called by Dr. Franklin the *golden fly*. If the *electrical* BELLS, already described, be hung from the same conductor, the ringing and dancing will accompany each other; and the amusement may be heightened, by occasionally touching the prime conductor with a finger or brass rod, which would make both to cease at once; and when the finger or rod is removed, both will be renewed. If the application of the finger or rod be artfully concealed, the figures might be made to dance, and the bells to ring, seemingly at the word of command. In this experiment, the light bodies, and the lower plate, being within the atmosphere of the upper electrified plate, become possessed of a contrary *electricity*, by communicating part of their natural quantity to the conductors with which they are connected; and thus being differently electrified, attract each other; but when these bodies touch the upper plate, they are endued with the same *electricity*, and are instantly repelled to the lower plate, which, being electrified with a contrary *electricity*, assists in repelling them back again to the upper one. If the lower plate Y, and its stand, be removed, and the light bodies be put upon a clean dry pane of glass, and held by one corner under the plate X, the experiment would not succeed; because they cannot part with any of their natural quantity of the fluid, and become possessed of an *electricity* contrary to that of X; but if a finger, or any conductor, be presented to the lower side of the glass, the attraction and repulsion will take place, because the bodies will now part with their *electricity* to the upper surface of the glass, and charge it, the *electric* fluid belonging to the lower surface being repelled and carried away by the conductor. If the prime conductor were electrified negatively, the effect would be the same; but the *electricity* of the plates would be reversed, the upper plate being electrified negatively, and the lower plate electrified positively. If a person, standing on an insulating stool, and having in his hand a chain fastened to the prime conductor, stretch the other hand over the light substances on the lower plate, they will perform the dances already described.

8. Let a bent wire CDE (*fig.* 20. *Tab.* III.) be fastened to the outside of a coated jar, and be so bent as to have its knob E at the same height with the knob A of the jar; let a piece of cork be cut in the shape of a spider, and linen threads be drawn through it with a needle, and cut to a proper length to represent its legs; and then suspended by a silk thread, so as to hang exactly in the middle between the knobs A and E; charge the jar, by bringing the knob A in contact with the prime conductor, and place it exactly where it stood before it was charged; the spider will now begin to move from knob to knob, stretching his legs towards each ball as he approaches it, and grasping each ball with them when he touches it, as if he were really animated, and continue its motion for a considerable time, till the jar is almost discharged. The spider is first attracted by the knob A, which communicates with the inside of the bottle, and receiving part of its *electricity*, is repelled, and discharges it on the knob E, communicating with the outside of the jar; and it is then alternately attracted and repelled by A and E, till the discharge is nearly completed, and the equilibrium between the opposite *electricities* of the inner and outer surfaces of the jar is nearly restored.

9. Let a metal cup, almost full of water, be suspended by a loop or bow from the prime conductor, and the winch of the machine be turned, so as to electrify the water; and a finger be held then perpendicularly over the water, and very near it, the electrified water will rise in a cone towards the end of the finger, and, in a dark room, a stream of fire will be seen to issue from the water to the finger. If one leg of a glass syphon be put into this water, and the other leg be drawn out into a capillary bore, that the water may only just drop out of it, and the water be electrified, it will run in a continued stream, which, in the dark, will be beautifully illuminated. If an unelectrified person with his finger, or a piece of metal, touch the prime conductor, the stream will stop, and the light disappear; and when the metal is removed, both will be renewed.

10. Electric attraction and repulsion may be exhibited by means of the electric light, by fixing two pointed wires, one in the prime conductor, and the other in the rubber; when the winch is turned, the point of the former wire will be illuminated with a BRUSH or PENCIL, and that of the latter with a STAR: if an excited glass tube be brought near the first wire, the brush will be turned aside or repelled by the atmosphere of the tube;

tube; and if it be held directly oppoſite to the point, the bruſh will vaniſh: but if the excited tube be brought near the point of the wire, fixed upon the rubber, the ſtar will turn towards the tube, the wire in this caſe attracting and receiving the *electricity* of the tube. If an excited ſtick of ſealing wax or other ſubſtance negatively electrified be applied in the ſame manner, the appearances will be directly the reverſe.

11. If a fly, as D *fig.* 4. *Tab. Electricity*, made of ſmall braſs wires and fixed in a braſs cap, be put upon the pointed wire K, and screwed to the prime conductor, and the wires *a*, *b*, *c*, *d*, are pointed, and bent in the ſame directions; when the winch of the machine is turned, a flame will be ſeen at each point, and the fly will turn round in the direction of the letters *a*, *b*, *c*, *d*, contrary to that of the points of the wires; for the air, contiguous to the points, becomes poſſeſſed of a ſtrong *electricity*, of the ſame kind with that of the points, and therefore the air and the points will repel each other. The experiment may be rendered more amuſing, by faſtening the figures of horſes cut in paper to the wires, in ſuch a manner, that the points may be in their tails, and then the horſes will ſeem to purſue each other; whence the experiment is called the electrical horſe-race. If a circular plate of metal be cut into the ſhape of a ſtar, ſo that every point may be at the ſame diſtance from the centre, and the centre be made to turn freely on a point, like the wires in the preceding experiment, a ſmall flame will be ſeen at every point; and if the ſtar be turned round, it will exhibit the appearance of a lucid circle, without any diſcontinuance of the light.

12. The effects of electrical attraction and repulſion may be repreſented in a very ſtriking manner, by electriſying a hoop of metal, ſuſpended from the prime conductor, about half an inch above a plate of metal, and parallel to it; and placing a round glaſs bubble, blown very light, upon the plate near the hoop: the bubble will be immediately attracted to the hoop, and the part which touches it acquiring *electricity* from it, will be repelled; but, as the electric virtue is not diffuſed over the whole ſurface of the glaſs, part of it will be again attracted by the hoop, whilſt the electrified part goes to diſcharge its *electricity* upon the plate; and this will occaſion a revolution of the bubble round the hoop, as long as the electrification is continued. In a dark room the glaſs ball will be beautifully illuminated. Two balls may be made to move round the ſame hoop, one on the inſide and the other on the outſide, in the ſame, or in oppoſite directions: if more hoops are uſed, a greater number of bubbles may be made to revolve, and a kind of planetarium or orrery be conſtructed, with a ball over the centre of the hoop, to repreſent the ſun in the centre of the ſyſtem.

13. If a metal rod with a round knob be preſented to the electrified prime conductor, the electric matter will paſs with violence from the one to the other; an electric ſpark, with the appearance of fire, will be ſeen darting between them, and a report, uſually compared to a ſnapping noiſe, will be heard. The longeſt and ſtrongeſt ſpark will be drawn from that end of the prime conductor which is fartheſt from the cylinder, or from the knob I of the rod B I fixed at the end of it. See *fig.* 4. *Tab. Electricity*. This ſpark will iſſue in a great variety of crooked directions, exactly reſembling the courſe of lightning; and the repreſentation of it may be ſeen, *fig.* 10. *Tab.* III. A friend of Dr. Franklin ſuppoſes, that the ſpark is thrown out of a ſtraight courſe by the denſity of the air, increaſed by the action and re-action of the two fluids, which are repelled of one another. Franklin's Letters, p. 167. If the braſs plate X (*fig.* 17. *Tab.* II.) be hung on the prime conductor, and the room be darkened, ſtreams of fire will be ſeen to iſſue from the plate to the knuckles, held near the edge of it, and to follow the hand moved round its edge, when the conductor is electrified. The electric light may be made to flaſh between two metallic plates, if they are held back to back, parallel to one another, and about two inches aſunder, the one by an inſulated perſon connected with the prime conductor, and the other by a perſon ſtanding on the floor. When the winch of the machine is turned, flaſhes of light may be obſerved between the two plates ſo denſe and ſo frequent, that any thing may be diſtinguiſhed in a dark room. Sparks may be alſo drawn from any part of the body of a perſon inſulated and connected with the prime conductor. They may be communicated from a ſmooth ball of metal annexed to a wire held in the hand of the inſulated perſon to any other on the floor.

14. If two perſons be inſulated, and one of them be electrified poſitively, and the other negatively, either of them touching a perſon ſtanding on the floor will give a moderate ſpark; but if they touch one another, the ſpark will be much ſtronger, and they will both be unelectrified, the redundancy of the one ſupplying the deficiency of the other; but if both perſons had been electrified either poſitively or negatively, there would have been no ſpark on their touching one another.

15. There are various methods of ſetting fire to inflammable ſpirits by the electric ſpark. This may be eaſily done, by ſuſpending from the prime conductor a ſhort rod, with a ſmall knob at its end, and then putting ſome ſpirits of wine, a little warmed, into a metal ſpoon, which ſhould be held about an inch below the knob. If the winch is turned, a ſpark will proceed from the knob and kindle the ſpirits. If a perſon ſtanding on an inſulated ſtool, communicating with the prime conductor, holds the ſpoon in his hand, and another perſon on the floor brings his finger, or a piece of ice within a ſmall diſtance of it, the ſpirits will be ſet on fire; or, the ſpirits may be held by the perſon on the floor, and the inſulated perſon may communicate the ſpark by any conductor. Many other ſubſtances which throw out an inflammable vapour, may be kindled in the ſame manner.

16. Gun-powder may be fired by filling a ſmall cartridge of paper or the tube of a quill with it, and inſerting two wires, one at each end, ſo that their ends within the quill or cartridge may be about one fourth or one-fifth of an inch from one another; then, if the charge of a phial be conveyed through theſe wires, the ſpark paſſing from the inner end of one to that of the other, will ſet fire to the gun-powder. Steel-filings mixed with the powder will make it take fire more readily.

17. The electric light is moſt beautifully exhibited in glaſs tubes and phials, exhauſted of their air. Thus, if a glaſs tube, about two inches in diameter, and about two feet long, with a braſs cap fixed to one end, and a ſtop-cock or valve to the other, be exhauſted of its air, it will appear to be full of light, whenever a ſpark is taken by it from the prime conductor, or an electric is diſcharged through it. Thus alſo, if a wire be made to paſs through a tall receiver of an air-pump, and the end of the wire within the receiver be moderately pointed, and the other end furniſhed with a knob; when the receiver is exhauſted of its air, and the knob of the wire brought into contact with the prime conductor, every ſpark will paſs through the receiver in a large diverging body of light, from the wire to the plate of the air-pump. Dr. Watſon has given us a particular account of ſeveral curious phenomena of *electricity* in vacuo, in the Philoſophical Tranſactions, vol. xlvii. p. 362, &c. The electric fluid, in its paſſage through an exhauſted tube, nearly three feet in length, and almoſt three inches in diameter, affords a very agreeable ſpectacle in a darkened room. We may obſerve, not as in the open air, bruſhes or pencils of rays an inch or two in length, but corruſcations extending through the whole length of the tube; that is, in his experiment, thirty-two inches, and of a bright ſilver hue. Theſe did not immediately diverge, as in the open air, but frequently, from a baſe apparently flat, divided themſelves into leſs and leſs ramifications, and reſembled very much the moſt lively corruſcations of the aurora borealis. At other times, when the tube has been exhauſted in the moſt perfect manner, the *electrum* has been ſeen to paſs between two braſs plates, contrived ſo, that they might be placed at different diſtances from each other, in one continued ſtream, of the ſame dimenſions through its whole length. The ſame experiments were tried with a Torricellian vacuum, very ingeniouſly contrived by lord Charles Cavendiſh. The apparatus (ſee *fig.* 21. *Tab.* III. *Electricity*) conſiſted of a cylindrical glaſs tube of about three inches of an inch in diameter, and of ſeven feet and a half in length, bent in ſuch a manner, that thirty inches of each of its extremities were nearly ſtraight, and parallel to each other, from which an arch ſprung, which was likewiſe of thirty inches. This tube was carefully filled with mercury; and each of its extremities being put into its baſon of mercury, ſo much of the mercury ran out, until, as in the common barometrical tubes, it was in equilibrio with the atmoſphere. Each of the baſons containing the mercury was of wood, and was ſupported by a cylindrical glaſs, of about four inches in diameter, and ſix inches in length; and theſe glaſſes were faſtened to the bottom of a ſquare wooden frame, ſo contrived, as that to its top was ſuſpended by ſilk lines, the tube filled with mercury before mentioned, ſo that the whole of this apparatus might be moved together without inconvenience. The Torricellian vacuum then occupied the ſpace of about thirty inches. In making the experiment, when the room was darkened, a wire from the prime conductor of the electrical machine communicated with one of the baſons of mercury; and any conductor touching

touching the other bason, while the machine was in motion, the *electricity* pervaded the vacuum in a continued arch of lambent flame; and, as far as the eye could follow it, without the least divergency. S. Beccari obferves, that no electric light is vifible in a barometer, in which there is a perfect vacuum, and hence infers, that electric light is vifible only by means of fome vibrations which it excites in the air; and Mr. Walfh has lately difcovered, that an electric fpark would no more pafs through a vacuum of the more perfect kind, made in the above-defcribed arched barometer by the affiftance of Mr. de Luc, than through a ftick of folid glafs. Mr. Nairne conftructed a barometer on purpofe to repeat this experiment; but his was a common ftraight tube, in which the mercury was loofe; and he affirms, that it was as perfect a vacuum as art could make; but the vacuum of this became perfectly luminous at three feet from the large conductor to the grand-duke of Tufcany's machine. Note, Mr. Walfh's was the arched barometer of lord Charles Cavendifh before mentioned, and the defign of Mr. de Luc in preparing it, was to render the illuminated vacuum more beautiful. *See* AURORA *borealis* and *Luminous* CONDUCTOR.

18. There have been many contrivances for giving various forms to the appearance of the electric fpark in its paffage from one conductor to another. This may be done by means of a board, and a number of wires, in the following manner: let two holes be made through the board, about one-fourth of an inch on each fide of the fpot where a fpark is defired; let the extremities of the wires, neatly rounded, come through thefe holes, and be brought near together, exactly over the place; and let the wires on the backfide of the board be fo difpofed, as that an electric fpark muft take them all in the fame circuit. When they are thus prepared, all the points will appear luminous at once, whenever a fpark is taken by them at the prime conductor. In this manner, fays Dr. Priefley, beautiful reprefentations may be made of any of the conftellations, as of the Great Bear, Orion, &c. and thus alfo may the outlines of any drawing, as of figures in tapeftry, be reprefented.

A fpiral line of fire may be exhibited by the inftrument in *fig.* 22. *Tab.* III. compofed of two glafs tubes, C D, one within another, and clofed with two knobbed brafs caps, A and B: the innermoft tube has a fpiral row of fmall round pieces of tin-foil ftuck on its furface, at the diftance of about one thirtieth of an inch from each other. If one end of this inftrument be prefented to the electrified prime conductor, every fpark will be feen to pafs with a fpiral motion from one of thefe pieces to the other round the fmall tube. Pieces of tin-foil may alfo be difpofed of on a flat piece of glafs A B C D (*fig.* 23.) fo as to reprefent flowers, letters, &c. and they may be illuminated by holding either extremity C or B, in the hand, whilft the other is prefented to the electrified prime conductor.

19. Thefe are various ways of receiving and tranfmitting the electric fhock. If a perfon puts one hand to the outfide of the charged jar, and the other hand to the wire, he will receive a fhock through his arms and breaft. If a number of perfons join their hands, or for the fake of varying the experiment, tread on one another's toes, or lay their hands on each other's heads, and a perfon at one end of the circuit touch the outfide of a jar, whilft a perfon at the other extremity touches the wire, the fhock will be felt by all at the fame time. The fhock may alfo be communicated, if a bafon of water be placed between every two of the perfons who are to receive it, and they dip the fingers of the hands in the water, that would otherwife have been joined. *See* CIRCUIT. Electric fhocks may likewife be given to any particular part of the body, without affecting the reft, by bringing that part only into the electrical circuit: thus, if a chain connected with the outfide of a jar charged by the prime conductor, be tied with a filk ftring or ribband to the elbow, and another chain be applied in the fame manner to the fhoulder, and brought into contact with the prime conductor, the fhock will only be felt from the fhoulder to the elbow. *See Medical* ELECTRICITY and ELECTROMETER.

A very convenient apparatus hath been contrived for this purpofe by Mr. Henly, which hath been much approved. A curious apparatus hath alfo been contrived by Mr. Partington, which he very properly calls directors of the fhock, and by which it may with great facility be determined to any part of the body. Mr. Birch hath very confiderably improved the electrical apparatus for medical purpofes; for an account of which, fee Adams's Eflay on Electricity, p. 328, &c. octavo. 1785.

20. If a few fheets of a quire of paper, or the cover of a book or a card, be interpofed in the circuit of an electrical explofion, they will be perforated by the difcharge, and the hole will give a ftrong fmell of fulphur.

21. The direction of the electric fluid in a difcharge, may be fhewn, by caufing the explofion to pafs over the furface of a card, in the following manner: lay two wires, one on one fide of the card, and the other under it, in the fame direction, and with their extremities about an inch diftant; then by connecting one of the wires with the outfide of a charged jar, and the other wire with the knob of the jar, the electric fluid will run over that furface of the card, upon which the wire lies that is connected with the pofitive fide of the jar; and in order to pafs to the extremity of the other wire, it will break a hole through the card juft over the extremity of the wire that is connected with the negative fide of the jar. This is a curious experiment of Mr. Lullin, but the honourable Frederic Chriftian Maluing, counfellor of ftate at Copenhagen, has admirably improved this experiment, by firft painting the card in a line about half an inch broad on each furface with vermilion. Mr. Henly has prefented an account of it to the Royal Society; for which, fee Phil. Tranf. vol. lxviii. part ii. art. 49.

22. The courfe of the electric fluid may alfo be exhibited by the following experiment of Mr. Henly: a fmall phial, reprefented *fig. 24. Tab.* III. is coated on the outfide, about three inches from the bottom, with tin-foil; to the top is cemented a brafs cap with a hole and valve, and from the cap a wire proceeds within the phial, terminating in a blunt point. When the phial is exhaufted of its air, a brafs ball is forwed on the cap to defend the valve, and prevent air from getting into the exhaufted phial. If this phial be held by its bottom, and the brafs knob be prefented to and held in contact with the prime conductor electrified pofitively, the electric fluid will caufe a pencil of rays to proceed from the wire within the phial, as in *fig.* 201 and if it be difcharged, a ftar will appear in the room of the pencil, as in *fig.* 24: but if the phial be held by the brafs cap, and its bottom be made to touch the prime conductor, then the point of the wire within it will appear illuminated with a ftar, when charging, and with a pencil, when difcharging. All thefe appearances will be reverfed, when it is prefented to a conductor electrified negatively. *See Luminous* CONDUCTOR.

23. The direction of the electric fluid may alfo be exhibited by fixing to the end of the prime conductor, remotell from the machine, a brafs rod fix inches long, with a brafs ball at its extremity, about three-tenths of an inch in diameter; and when the winch of the machine is turned, let the flame of a wax taper be prefented to the ball, and it will be blown almoft horizontally from the ball, and in the direction of the electric fluid; but if a like wire and ball be fixed to the infulated rubber, the flame of a wax taper prefented to the ball, will be blown upon the ball, fhewing the true courfe of the fluid in its paffage to the rubber that is receiving it.

Experiments with the Electrical Battery. See ELECTRICAL *Battery* and *Univerfal* DISCHARGER.

Experiments with the Leyden Phial. See LEYDEN *Phial.*

Experiments on the Ufe and Effects of Points. See POINTS.

ELECTRICITY, *Medical.* It is natural to imagine, that a power of fuch efficacy as that of *electricity* would be applied to medical purpofes; accordingly it has been found, invariably, to increafe the fenfible perfpiration, to quicken the circulation of the blood, and to promote the glandular fecretion; (though from a late experiment it has been inferred, that fimple *electricity* does not accelerate the pulfe;) accordingly, many inftances occur in the later period of the hiftory of this fcience, in which it has been tried with conliderable advantage and fuccefs. Among the variety of cafes to which it has been applied, there are none in which it feems to have been prejudicial, except thofe of pregnancy and of the venereal difeafe. In moft diforders, in which it has been ufed with perfeverance, it has given, at leaft, a temporary and partial relief, and in many, effected a total cure. The firft inftance that occurs of its falutary effect, is that of a woman, who was cured in a quarter of an hour of a contracted finger, by M. Kratzenftein, at Halle, as early as the year 1744. It was afterwards applied in a variety of paralytic cafes, by M. Jallabert of Geneva, in 1749; M. Sauvages, of the academy in Montpellier; in the courfe of whofe experiments, it appeared, that electrification increafes the circulation of the blood about one-fixth; Dr. Price, Brydune in Scotland, in 1757; the Abbé Nollet, and others; in feveral of which cafes prefent relief was obtained; but the beneficial effect does not appear to have been permanent. One inftance occurs, related by Dr. Hart, of Shrewfbury, and recorded in the Philofophical Tranfactions, vol. xlviii. part ii. p. 785, in which electrification was injurious, and brought an univerfal palfy on a young perfon, whofe right arm was paralytic; and though this palfy was removed by a courfe of medicine, the diftafed arm remained incurable. It alfo appears, from a number of experiments made by Dr. Franklin in paralytic cafes, that no permanent advantage was derived from *electricity* in this diforder; and Mr. Wefley, who has

been long engaged in a courſe of medical *electricity*, obſerves, that though many paralytics have been helped by it, no palſy of a year's ſtanding has been thoroughly cured by it. However, a remarkable inſtance more lately occurs, in which an hemiplegia was cured by this means, under the direction of a phyſician at Greenwich. The patient was in ſuch a ſtate, that boiling water might be applied from her hand to her ſhoulder, and from her ſhoulder to her foot, on the diſeaſed ſide, without being felt. This perſon was electrified, by drawing ſparks from the palſied ſide, and giving ſhocks, beginning with ſtronger ſhocks, till ſhe began to feel them, and continuing moderate ones, for 18 days; and in that time, during 31½ hours, the number of ſhocks was 1441; and this perſeverance was attended with ſuch ſucceſs, that her feeling was quite reſtored, and that ſhe became capable of walking, and of writing with the hand, the uſe of which ſhe had loſt. Dr. de Haen obſerves, that with reſpect to partial palſies, electrification never did the leaſt harm; and that one or two perſons, who had received no benefit from it in ſix entire months, were yet much relieved by perſevering in the uſe of it; and that ſome perſons diſcontinuing it, after having received ſome benefit, relapſed again; but afterwards, by returning to the uſe of *electricity*, recovered, though more ſlowly than before.

Dr. Haſt, in 1756, mentions a cure performed on a woman, whoſe hand and wriſt had been for ſome time rendered uſeleſs, by a violent contraction of the muſcles; but the moſt remarkable caſe of this kind is that related by Dr. Watſon, Phil. Tranſ. vol. liii. p. 10. The patient, about ſeven years of age, was ſeized with an univerſal rigidity of her muſcles, ſo that her whole body felt more like that of a dead corpſe than of a living perſon: Dr. Watſon electrified her, at convenient intervals, from the middle of November 1762 to the end of January 1763, when every muſcle of the body was perfectly flexible, and ſubſervient to her will, ſo that ſhe could ſtand, walk and run like other children of her age. Mr. Miles Partington has lately communicated to the Royal Society a ſurpriſing inſtance of the cure of a very great degree of contraction and rigidity in the ſterno-maſtoideus muſcle, by means of electrical ſparks and ſhocks. Phil. Tranſ. vol. lxviii. part i. p. 67, &c. Mr. Wilſon mentions a ſingle inſtance, in which he had cured deafneſs of ſeventeen years continuance; but he acknowledges, that he tried ſimilar experiments on ſix other deaf perſons without ſucceſs. Mr. Lovet and Mr. Weſley have extended the medical application of *electricity* to a greater variety of caſes than any others: Mr. Lovet obſerves, in his Eſſay, that *electricity* is almoſt a ſpecific in all caſes of violent pains, of however long continuance, in any part of the body; as in obſtinate head-achs, the tooth-ach, the ſciatica, the cramp, and diſorders reſembling the gout; and that it has ſeldom failed to cure rigidities, or a waſting of the muſcles, and hyſterical diſorders: he adds, that it cures inflammations, and a fiſtula lachrymalis; that it has ſtopped a mortification, and diſperſed extravaſated blood; that it has been of excellent uſe in bringing to a ſuppuration, or in diſperſing without ſuppuration, obſtinate ſwellings of various kinds, even thoſe that were ſcrophulous; that it has cured the falling-ſickneſs, and ſeveral kinds of fits, and a diſorder that ſeems to have been a *gutta ſerena*. He adviſes to begin, in general, with ſimple electrification, eſpecially in hyſterical caſes; than to proceed to take ſparks, and laſtly to give moderate ſhocks. Mr. Weſley obſerves, that he has ſcarce known an inſtance, in which ſhocks all over the body have failed to cure a tertian or quartan ague; he mentions a caſe of blindneſs cured and relieved by it, and hearing given by it to a perſon who was born deaf; and he farther ſays, that it has cured bruiſes, running ſores, the dropſy, and a palſy in the tongue; and that it has brought away gravel from the kidnies. In hyſterical caſes, he recommends the patient's being ſimply electrified, by ſitting on cakes of reſin, at leaſt for half an hour morning and evening; and then taking ſmall ſparks from him, and afterwards giving ſhocks, more or leſs ſtrong, as the diſorder requires. Dr. Antonius de Haen, in his Ratio Medendi, cited by Dr. Prieſtley, Hiſt. *Electricity*, vol. i. p. 485, &c. informs us, that a paraliſis and trembling of the limbs, from whatever cauſe it aroſe, never failed to be relieved by *electricity*; and that it alſo certainly cures St. Vitus's dance; that it has been of ſome uſe in caſes of deafneſs; but failed in its application to a *gutta ſerena* and ſtrumous neck. Mr. Hey, ſurgeon of Leeds, mentions ſeveral caſes, in which the power of *electricity* has been ſucceſsfully applied to an AMAUROSIS. The machine was uſed twice a day; the patient was placed on a ſtool with glaſs legs, and had ſparks drawn from the eyes and parts ſurrounding the orbits, eſpecially where the ſuperciliary and infra-orbitary branches of the fifth pair of nerves ſpread themſelves. After this operation had been continued for half an hour, the patient was made to receive for an equal time ſlight ſhocks through the affected parts, which were ſometimes directed acroſs the head, from one of the temples to the other, but chiefly from the *ſupercilium* and *infra-orbitar foramina* to the *occiput*. Med. Obſ. and Inq. vol. v. p. 160. In rheumatic caſes, Mr. Ferguſon obſerves, that he has generally found *electricity* ſucceſsful, by continuing to take ſparks from the places where the pain lies, till the ſkin has been red and pimpled, and the patient has felt a glowing warmth where the ſparks were drawn off; and the ſame method has alſo proved effectual in old ſprains. The uſe of *electricity* has been lately recommended in caſes of ſudden death. See DROWNING.

In all caſes where ſhocks are given, gentle ones ſhould be firſt uſed; and if the diſorder continues, they may be gradually increaſed; and they ſhould be confined to the affected part. The efficacy of *electricity* in the tooth-ach is ſo great, that it ſeldom or ever fails to give immediate relief, unleſs the tooth be very much decayed. The following inſtrument will ſerve for this purpoſe: it conſiſts of two wires, A E and B E, fixed in the piece of baked wood H, and bent at C D and F G, and at A and B, as in *fig.* 25. *Tab.* III. *Electricity*. If the affected tooth be brought within the two wires at E, and the ring A or B be connected by a chain, with the outſide of a charged jar, and the other ring be connected by a chain with the knob of the jar, the ſhock will paſs through the wires, and conſequently through the tooth. The modes of applying *electricity* to the human frame, formerly uſed, were by the ſhock and ſpark, and ſometimes, though rarely, by ſimple electrification. Theſe modes are now varied and multiplied, according to the circumſtances of the patient, and the nature of his diſorder. Under the conduct of Mr. Birch, an eminent ſurgeon, who has particularly directed his attention to the improvement and application of medical *electricity*, and of other gentlemen of the profeſſion, we have reaſon to expect every degree of efficacy and ſucceſs of which it is capable. For an account of their medical apparatus, and of various modes of applying it in different diſorders, ſee Adams's Eſſ. on Electricity, chap. 15, octavo. 1785.

Dr. Cullen ſays, that *electricity*, when properly applied, is one of the moſt powerful ſtimulants that can be uſed to act upon the nervous ſyſtem of animals. Mr. Birch conſiders *electricity*, applied under the form of a fluid, as a ſedative, under that of a ſpark or friction, as a ſtimulant, and by way of a ſhock, as a deobſtruent, in its action.

Under this head of *medical electricity*, it may be proper juſt to mention thoſe medicated tubes, the imaginary virtues of which were firſt diſcovered by Signior Privati at Venice, and which were much recommended in the years 1747 and 1748, both in Italy and by Mr. Winkler at Leipſic. Theſe gentlemen imagined, that odorous ſubſtances, confined in excited glaſs veſſels, would tranſpire through the pores of the glaſs, and communicate their medicinal virtue to the atmoſphere of a conductor, and to all perſons in contact with it; and that theſe ſubſtances would yield their virtues by being held in the hands of perſons electrified; and they pretended that many cures were wrought in this way, by the operation of medicines, without being taken into the ſtomach: but the whole was ſoon diſcovered to be a fallacy; and it was incontrovertibly proved, that no effluvia could paſs from the included ſubſtances through the pores of excited glaſs; and that no method was known for cauſing the power of medicine to inſinuate itſelf into the human body by *electricity*. Dr. Franklin, by proving that glaſs was impermeable to the electric fluid itſelf; and that its *electricity* was collected from the rubber, &c. evinced the abſurdity of every attempt to tranſmit the effluvia of any ſubſtances through the glaſs. See Franklin's Letters, p. 82, &c.

ELECTRICITY, *Theory of*. It will be needleſs to recite the ancient hypotheſes on this ſubject, ſuch as that of the ſympathetic power of the Peripatetics, that of unctuous effluvia emitted by excited bodies, and returning to them again, adopted by Gilbert, Gaſſendus, Sir Kenelm Digby, &c. or that of the Carteſians, who aſcribed *electricity* to the globules of the firſt elements, diſcharged through the pores of the rubbed ſubſtances, and in their return carrying with them thoſe ſight bodies, in the pores of which they were entangled. Theſe hypotheſes were framed in the infancy of the ſcience, and of philoſophy in general, and have been long ſince exploded. In the more advanced ſtate of *electricity*, there have been two principal theories, each of which has had its advocates. The firſt we ſhall mention is that of two diſtinct electric fluids, repulſive with reſpect to themſelves, and attractive of one another, adopted by Mr. du Fay, on diſcovering the two oppoſite ſpecies of *electricity*, viz. the vitreous and reſinous, and ſince new-modelled by Mr. Symmer. Theſe two fluids are ſuppoſed to be equally attracted by all bodies, and to exiſt, in intimate union, in their pores; and in this ſtate to exhibit no mark of their exiſtence. The friction of an electric,

electric, by a rubber, separates these fluids, and caufes the vitreous *electricity* of the rubber to paſs to the electric, and then to the prime conductor of a machine, and the reſinous *electricity* of the conductor and electric to be conveyed to the rubber; and thus the quality of the electric fluid poſſeſſed by the conductor and the rubber is changed, but the quantity remains the ſame in each.

In this ſtate of ſeparation, the two electric fluids will exert their reſpective powers; and any number of bodies charged with either of them will repel each other, attract thoſe bodies that have leſs of each particular fluid than themſelves, and be ſtill more attracted by bodies that are wholly deſtitute of it, or that are loaded with the contrary. According to this theory, the electric ſpark makes a double current; one fluid paſſing to an electrified conductor from any ſubſtance preſented to it, whilſt the ſame quantity of the other fluid paſſes from it; and when each body receives its natural quantity of both fluids, the balance of the two powers is reſtored, and both bodies are unelectrified. Thus alſo, when a phial is charged by a conductor, the reſinous *electricity* of that ſide which is connected with the conductor is tranſmitted to the oppoſite ſide connected with the rubber, and an equal quantity of the vitreous *electricity* is returned from this ſide to the other; ſo that all the vitreous *electricity* is conveyed to one of the ſides, and all the reſinous to the other. In this ſtate they mutually attract each other through the ſubſtance of the intervening glaſs, are thus prevented from being drawn away by any force that can be applied to them ſeparately, and runs to one another by means of proper conductors. For a further account of the explanation of ſome of the principal phenomena of *electricity* by this theory, we ſhall refer the reader to Dr. Prieſtley's Hiſtory, vol. ii. § 3; who, with a philoſophical liberality, has ſtated it in its full force, though he adopts the other theory, which we ſhall now offer in as few words as the nature and importance of it will allow. This is commonly diſtinguiſhed under the denomination of *poſitive and negative electricity*, and was firſt ſuggeſted by Dr. Watſon, and digeſted, illuſtrated, and confirmed by Dr. Franklin; and has been ſince known by the appellation of the Franklinian hypotheſis. This theory ſuppoſes, that all the phenomena of *electricity* depend on one fluid, *ſui generis*, extremely ſubtile and elaſtic, diſperſed through the pores of all bodies, by which the particles of it are ſo ſtrongly attracted as they are repelled by one another. When bodies poſſeſs their natural ſhare of this fluid, or ſuch a quantity as they are capable of retaining by their own attraction, they are then ſaid to be in an unelectrified ſtate: but if the equilibrium is diſturbed, and they either acquire an additional quantity *from* other bodies, or loſe part of their natural ſhare by communication *to* other bodies, they exhibit electrical appearances. In the former caſe they are ſaid to be electrified poſitively, or *plus*; and in the latter, negatively, or *minus*. This electric fluid is ſuppoſed to *move* with great eaſe in thoſe bodies that are called conductors, and with extreme difficulty and ſlowneſs in the pores of ELECTRICS; whence it comes to paſs, that all electrics are impermeable to it. Moreover, electrics are ſuppoſed to contain always an equal quantity of this fluid, ſo that there can be no over-charge or increaſe on one ſide without a proportionable decreaſe or loſs on the other, and *vice verſa*; and as the electric does not admit the paſſage of the fluid through its pores, there will be an accumulation on one ſide, and a correſponding deficiency on the other. See CHARGE. When both ſides are connected together by proper conductors, the equilibrium will be reſtored by the redundant fluid's ruſhing from the over-charged to the exhauſted ſurface. Thus alſo if an electric be rubbed by a conducting ſubſtance, the *electricity* is only conveyed from one to the other, the one giving what the other receives; and if one be electrified poſitively, the other will be electrified negatively, unleſs the loſs be ſupplied by other bodies connected with it, as in the caſe of the electric and inſulated rubber of a machine. The manner in which this effect is produced, has not yet been ſufficiently explained: S. Beccaria ſuppoſes, that the ſurface of the electric is charged by the action of the rubber, and rendered capable of receiving a greater quantity of the electric fluid from it, which additional *electricity* appears on the ſurface of the electric, when the rubber is withdrawn, and the capacity of the electric is again contracted.

This theory ſerves likewiſe to illuſtrate the other phenomena and operations in the ſcience of *electricity*. Thus, bodies differently electrified will naturally attract each other, till they mutually give and receive an equal quantity of the electric fluid, and the equinbrium is reſtored between them. Beccaria ſuppoſes, that this effect is produced by the electric matter making a vacuum in its paſſage, and the contiguous air afterwards collapſing, and thereby puſhing the bodies together. Bodies having the ſame kind of *electricity*, whether it be poſitive or negative, will repel each other; becauſe neither the augmentation nor diminution of the electric fluid on the ſurface of any body can take place, unleſs that ſurface be contiguous to an electric, which can acquire a contrary *electricity* at a ſmall diſtance; and therefore the augmented or diminiſhed quantity, in endeavouring to diffuſe itſelf over every part of the ſurface of electrified bodies, on account of the attraction ſubſiſting between the electric fluid and all the particles of matter, will make the bodies recede from each other, ſo that a quantity of air may be interpoſed between their ſurfaces, ſufficient to acquire a contrary *electricity* at a ſmall diſtance from them.

The influence of points in drawing or throwing off the electric fluid, depends on the leſs reſiſtance which it finds to enter or paſs off through fewer particles than through a greater number, whoſe reſiſtance is united in flat or round ſurfaces. The electric light is ſuppoſed to be part of the electric fluid, which appears when it is properly agitated; and the ſound of an explоſion is produced by vibrations, occaſioned by the air's being diſplaced by the electric fluid, and again ſuddenly collapſing.

As to the nature of the electric fluid, philoſophers have entertained very different ſentiments: ſome, and particularly Mr. Wilſon, have ſuppoſed, that it is the ſame with the æther of Sir Iſaac Newton, to which the phenomena of attraction and repulſion are aſcribed; whilſt the light, ſmell, and other ſenſible qualities of the electric fluid are referred to the groſſer particles of bodies, driven from them by the forcible action of this æther; and other appearances are explained by means of a ſubtile medium diffuſed over the ſurfaces of all bodies, and reſiſting the entrance and exit of the æther, which medium is ſuppoſed to be the ſame with the electric fluid, and to be more rare on the ſurfaces of conductors, and more denſe and reſiſting on thoſe of electrics: but Dr. Prieſtley has ſhewn, that though they may poſſeſs ſome common properties, they have others eſſentially diſtinct; the æther is repelled by all other matter, whereas the electric fluid is ſtrongly attracted by it. Others have had recourſe to the element of FIRE; and from the ſuppoſed identity of fire and the electric fluid, as well as from the ſimilarity of ſome of its effects, the latter has been commonly called the electric fire: but moſt electricians have ſuppoſed, that it is a fluid *ſui generis*. The honourable Mr. Cavendiſh has publiſhed an attempt to deduce and explain ſome of the principal phenomena of *electricity* in a mathematical, ſyſtematical manner from the nature of this fluid, conſidered as compoſed of particles which repel each other, and attract the particles of all other matter, with a force inverſely as ſome leſs power of the diſtance than the cube, whilſt the particles of all other matter repel each other, and attract thoſe of the electric fluid, according to the ſame law. Phil. Tranſ. vol. lxi. part ii. p. 584—677. A ſimilar hypotheſis and method of reaſoning have been alſo propoſed by Mr. Epinus, in his Tentamen Theoriæ Electricitatis & Magnetiſmi.

Dr. Prieſtley concludes, from experiments made with a view of determining the effects of the electrical explоſion on different kinds of air, that the electric matter either is or contains PHLOGISTON, ſince he found that both produced ſimilar effects. Mr. Henly alſo apprehends, that the electric fluid is a modification of that element, which, in its quieſcent ſtate, is called phlogiſton: in its full active ſtate, *electricity*; and when violently agitated, fire: and he has collected a variety of facts and obſervations, which ſeem to render this hypotheſis at leaſt probable. It uniformly appears, that bodies poſſeſſing an equal quantity of phlogiſton, or thoſe of the ſame kind, as glaſs or metal, acquire little or no *electricity* by friction; and as the difference in this reſpect is greater, ſo much the more *electricity* does the one body acquire from the other; and that thoſe bodies which poſſeſs a greater quantity of phlogiſton give the electric fluid to thoſe that have leſs of it, or acquire a negative *electricity* when rubbed with ſuch bodies; and that thoſe which have little phlogiſton acquire *electricity*, or are electrified poſitively, by the uſe of the ſame rubbers. Perhaps we may be allowed to enlarge our views, and conſider the ſun as the fountain of the electric fluid, and the radiant light, the balls of comets, the *Aurora borealis*, *lightning*, and artificial *electricity*, as its various and not very diſſimilar modifications. See on this ſubject, beſides Dr. Prieſtley's Hiſt. of *Electricity*, vol. ii. part iii. § 1, 2, 3. Wilſon's Eſſay towards an Explication of the phenomena of *Electricity*, deduced from the Æther of Sir Iſaac Newton, p. 5. 1746. Wilſon and Hadley's Obſ. &c. p. 55. 1750. Franke's Eſſay on the Cauſe of *Electricity* 1746. Prieſtley on Air, vol. i. p. 180. 274, &c. Phil. Tranſ. vol. lxvii. part i. p. 129, &c. and Mr. Eeles's Letters on the ſame ſubject.

ELECTRICITY, *conducting*, is a term introduced by Signior Beccaria, to expreſs a particular phenomenon in this ſcience: if two electrified electrics are joined together, they will be found to adhere, and their *electricities* diſappear;

appear; but as soon as they are separated, they recover their *electricities*. Thus, in an experiment of Mr. Lane, first proposed by Mr. Eeles, if two glass plates with plane surfaces be laid on one another, and their outward surfaces be coated with tin-foil; and they are then charged, they will adhere very firmly to each other; but if they are separated, that plane, whose coating was presented to the prime conductor, in charging, will be positively electrified on both sides; and the other, whose coating was connected with the conductors, communicating with the earth, will be electrified negatively on both sides. If these plates be again laid together and discharged, they will appear, when separated, to be electrified; but the first plate will be negative on both sides, and the second positive. And if they are separated after the discharge in the dark, flashes of light will be seen between their inward surfaces; and these flashes will appear for a considerable time, whenever they are laid together, their coating is touched, and they are again separated; but they will gradually diminish, and at last vanish. Mr. Henly observes, that crown-glass will answer the purpose of this experiment as well as plate-glass; and that Dutch plates, treated in the same manner, and kept a little time before they are separated, will have each a positive and negative surface, and that the *electricity* of each surface is reversed in the discharge. He adds, that if a clean, dry, uncoated plate of looking-glass be placed between the two first plates, it will appear, after charging, to be negatively electrified on both sides; but if it be placed between the Dutch plates, it acquires, like them, a positive *electricity* on one surface, and a negative *electricity* on the other. Beccaria's Artificial Electricity, part ii. § 6. Phil. Trans. vol. lxvi. part ii. p. 517, &c. Id. vol. lxvii. part i. p. 98, &c. See ELECTROPHORUS.

ELECTROMETER, framed of ἠλεκτρον, and μετρον, *I measure*, is an instrument contrived for measuring the quantity, and determining the quality of electricity in any electrified body. Mr. Canton, previous to the invention of instruments of this kind, estimated the quantity of electricity in a charged phial, by presenting the phial with one hand to an insulated conductor, and giving it a spark, which he took off with the other; and he proceeded in this manner till the phial was discharged, and then determined the height of the charge by the number of sparks. The most simple *electrometer* is a linen thread, called by Dr. Desaguliers the *thread of trial*; which, if brought near to an electrified body, will be attracted by it; but this will do little more than determine, whether the body is in any degree electrified or not; without determining with any precision its quantity, much less its quality. The abbe Nollet used two threads, and shewed the degrees of electricity by the angle of their divergency exhibited in their shadow on a board placed behind them.

Mr. Kinnersley's ELECTROMETER is already described under the article ELECTRICAL *Air-Thermometer*.

Mr. Canton's ELECTROMETER consisted of two balls of cork, or pith of elder, nicely turned in a lathe to about the size of a small pea, and suspended on fine linen threads, about six inches long, which may be wetted in a weak solution of salt. See *fig.* 26. *Tab.* IV. *Electricity*. These may be kept in small boxes, of the length of the strings, that they may lie in them without being bent; and they may be thus carried in the pocket and will be ready for use. See *Pocket* ELECTROMETER.

If the box containing these balls be insulated, by placing it on a drinking glass, or any other electric substance, and an excited smooth glass tube be brought near them, they will first be attracted by it, and then repelled both from the glass, and from each other; but on the approach of excited wax, they will be attracted, gradually approach, and come together; and *vice versa*. This apparatus will also serve to determine the electricity of the clouds and air, by holding them at a sufficient distance from buildings, trees, &c. for if the electricity of the clouds or air be positive, their mutual repulsion will increase by the approach of excited glass, or decrease by the approach of amber or sealing-wax; and if negative, their repulsion will be diminished by the approach of excited glass, and increased by amber or sealing-wax. See an account of Mr. Canton's curious experiments with this apparatus in the Phil. Trans. vol. xlvii. part i. part ii.

If two balls of this kind are annexed to a prime conductor, as in *fig.* 17. *Tab.* II. *Electricity*, they will serve to determine the degree and quality of its electrification, by their mutual repulsion and divergency. *Electrometers* of this kind may be combined, as in *fig.* 27. *Tab.* IV. in which B represents a pillar of wax, glass, or baked wood resting on a wooden base A. From the top, project four arms of glass, or of baked wood, supporting four *electrometers*; two of which, D, D, are silken threads, about eight inches long, to each of which a small downy feather is annexed; the other two, C, C, are formed of a stick of glass, as *a b*, about six inches long, covered with sealing-wax, and terminated at the upper end by a ring; from the lower end are suspended two fine linen threads, *c c*, about five inches long, each of which has a small cork or pith ball, about an eighth of an inch in diameter. The balls, in the figure, are represented in a state of electrification and repulsion; the glass handle *a* serves for an insulating handle, by which it may be supported, wherever it is used, without the stand A B. Cavallo's Electr. p. 161.

ELECTROMETER, *the discharger*, represented in *fig.* 18. *Tab.* III. was invented by Mr. Lane. It consists of brass work, G, the lower part of which is inclosed in the pillar F, made of wood, baked, and boiled in linseed oil, and bored cylindrically about two-thirds of its length; the brass work is fixed to the pillar by the screw H, moveable in the grooved, so that it may be raised higher or lower, as the height of the jar D requires. Through the brass work is made to pass a steel screw, I, the distance of whose threads is about one twenty-fourth of an inch, to the end of which, and opposite to K, a polished hemispherical piece of brass, fixed to the prime conductor, is fixed a well polished ball of brass, M. To this screw is annexed a circular plate, O, divided into twelve equal parts, and in every revolution of the screw, pointing to the divisions of the scale N: each of which divisions is equal to each turn of the screw. The use of this *electrometer* is to discharge a jar, D, or any battery connected with the prime conductor, without a discharging-rod (see *Universal* DISCHARGER); and to give flashes successively of the same degree of strength; and on this account it is particularly adapted for medical purposes. Then, if a person holds a wire, fastened to the screw H in one hand, and another wire fixed to E, a loop of brass wire passing from the frame of the machine to a tin-plate, on which the phial D stands, he will perceive no shock, when K and M are in contact; and the degree of explosion, as well as the quantity of electricity accumulated in the phial, will be regulated by the distance of K and M from each other. Phil. Trans. vol. lvii. p. 415. The surfaces of the balls, K and M, are very liable to lose their polish by explosion, and in this case the instrument becomes unfit for use. But this is an inconvenience, to which the *quadrant* ELECTROMETER of Mr. Henly is not subject. This instrument consists of a stem C, (*fig.* 28. *Tab.* IV.) terminating at its lower end with a brass ferrule and screw D, by means of which it may be fixed to a hole in the prime conductor, or to a knob of a jar or battery, or to a stand, as occasion requires: and at its upper end in a ball E. B represents a graduated semicircle of ivory, on the centre of which the index A, being an exceeding light rod, with a cork ball at its extremity, reaching to the brass ferrule of the stem, is made to turn on a pin in the brass piece F, so as to keep near the graduated limb of the semicircle. The stem and index are box, well rounded, and made smooth with emery paper. When the *electrometer* is not electrified, the index hangs parallel to the stem C; but as soon as it begins to be electrified, the index, repelled by the stem, will begin to move along the graduated edge of the semicircle (see E, *fig.* 4. *Tab. Electricity*), and mark, with the utmost exactness, the degree in which the prime conductor, &c. is electrified, or the height to which the charge of any jar or battery is advanced. This instrument, being made of materials that are very imperfect conductors, will not dissipate the electricity which it receives. Phil. Trans. vol. lxii. p. 359, &c.

Mr. Henly hath also very much improved Mr. Lane's *electrometer*, by taking away the screw, the double milled nut, and the sharp-edged graduated plate. His improved discharger is made as follows: a spring tube is supported by a socket of brass, which slips upon a supporter of glass. Through the spring tube passes, in an horizontal direction, a thick rod, or tube, of metal, furnished with a ball at each end. Two or three inches, at one end of this tube, are divided into tenths of an inch; and when the instrument is to be used, the ball at one end of the rod is made to touch the end of the spring tube, in which the horizontal rod, or tube, moves, and the ball at the other end of the same rod, or tube, at the same time, touches the prime conductor. The rod being then drawn back to any given distance, the end of the spring tube, through which it passes, cuts the divisions upon the rod, or tube, and shews to the one-tenth of an inch the distance the ball near the conductor has been separated from it, and consequently the length of the space of air through which the charge of electricity is to strike.

Mr. Henly's discharger of this kind has two tubes, one sliding within the other, in order to lengthen, and thus accommodate it to larger apparatus.

The following ELECTROMETER was contrived by Mr. Cavallo for observing the electricity of the atmosphere. It consists of a common jointed fishing-rod, A B, *fig.* 29. *Tab.* IV. without the last, or smallest joint. From the extremity of this rod proceeds a slender glass tube C, covered with sealing-wax, and having a cork D at its

end, from which a pith-ball *electrometer* is suspended. HG I is a piece of twine, fastened to the other end of the rod, and supported at G by a small string FG. At the extremity of the twine I, a pin is fastened, which, when pushed into the cork D, renders the *electrometer* E uninsulated. In this state the instrument, held by the end A, is projected upwards from an higher window into the air, so as to make an angle of about 50° or 60° with the horizon; and when it has been kept in this situation for a few seconds, the pin is disengaged from the cork D, by pulling the twine at H, which then falls into the situation LK, leaving the *electrometer* insulated and electrified with an electricity contrary to that of the atmosphere. The instrument is withdrawn, and the quality of the electricity examined without any obstruction from wind or darkness.

The same ingenious electrician has contrived a *Rain*-ELECTROMETER, which is a strong glass tube, ABCI, *fig.* 30. about two feet and a half long, with a tin funnel, DE, cemented to its extremity, and defending part of it from the rain. The tube is covered with sealing-wax from A to B, and also under the funnel. FD is a piece of cane, round which several brass wires are twisted in different directions, so as to catch the rain, without resisting the wind; the cane is fixed into the tube, and a slender wire passes from it through the tube to the strong wire AG, thrust through a piece of cork at the end A of the tube; from a ring at G, at the end of this wire, a pith-ball *electrometer* is suspended. The instrument is fastened to the side of a window-frame, by strong brass hooks at CB, the part FC is out of the window, and the end F a little elevated above the horizon; the remaining part passes into the room through a hole in a glass of the sash. This instrument is frequently electrified, when it rains, especially by flying showers; and the divergency of the *electrometer* shews the quantity and quality of the electricity it receives. Mr. Cavallo observes, that the rain is generally electrified negatively, and sometimes to such a degree, that he has been able to charge a small coated phial at the wire AG.

Mr. Cavallo has also described a convenient *Pocket* ELECTROMETER. The case of this *electrometer* is a glass tube, *fig.* 31, and 32. *Tab.* IV. about three inches long and three-tenths of an inch in diameter, half of which is covered with sealing-wax; to the uncovered end a loop of silk is fixed, which serves for occasionally suspending the *electrometer*; and to the other extremity a cork is adapted, which, by tapering at both ends, may be made to fit the tube with either extremity. From one end of the cork two linen threads proceed, somewhat shorter than the glass tube, and bearing little cones of pith of elder. When the instrument is used, the cork is inserted in the tube, so that the cones of pith may hang outward, as in *fig.* 31. When it is carried in the pocket, the cork stops it, and the cones hang freely within the tube, as in *fig.* 32. This *electrometer* may be kept in a case, like a common tooth-pick case, *fig.* 33. closed at one end, A, with a piece of amber, which will serve to electrify the instrument negatively; and at the other end with a piece of ivory, fastened to a piece of amber BC; the amber insulates the ivory, which, in this insulated state, by being rubbed against woollen cloths, acquires a positive electricity, and will serve to electrify the *electrometer* positively. Phil. Trans. vol. lxvii. part i. p. 48, &c. part ii. p. 309. or Cavallo's Electr. p. 370, &c.

Mr. Cavallo has invented a third *electrometer*, perfectly enclosed in a phial, which is a very curious invention, and very sensible in its operation. For an account of a lately invented *electrometer* by Mr. Brook, see Phil. Trans. vol. lxvii. part, ii. p. 384.

ELECTROPHORUS, derived from ηλεκτρον, and φερω, *I bear*, is an instrument, or machine, invented by M. Volta, of Como, near Milan, in Italy, for exhibiting perpetual electricity. This machine consists of two plates, (see *fig.* 34) one of which, B, is a circular plate of glass, covered on one side with some resinous electric, as beeswax and resin, or equal parts of resin, shell-lac, and sulphur, and the other, A, is a plate of brass, or a circular board, coated with tin-foil, and furnished with a glass handle I, which may be screwed into its centre by means of a brass or wooden socket. If the plate B be excited by rubbing it with new white flannel, and the plate A be applied to its coated side, a finger, or any other conductor, will receive a spark on touching this plate; and if the plate A be then separated, by means of the handle I, it will be found strongly electrified with an electricity, contrary to that of the plate B. By replacing the plate A, touching it with the finger, and separating it again, it will be found electrified as before, and give a spark to any conductor, attended with a snapping noise; and by this means a coated phial may be charged. The same phenomena may be repeatedly exhibited, without any renewed excitation of the electric plate B. The electric power of B has continued for several days, and even weeks, after excitation, though there is no reason for imagining that it is perpetual. Mr. Cavallo prepares this machine, by coating the glass-plate with sealing-wax; and with a plate of this kind, no more than six inches in diameter, once excited, he has given a charge to a coated phial, which was sufficient to pierce a card; the other plate, separated from it, has emitted strong flashes to the table on which the electric plate rested, and to the surrounding air; and the power has been so strong, that the two plates have adhered together, and the coated glass has been sustained by the upper plate. Instruments of this kind have been made with plates twelve or fifteen inches in diameter, which have afforded a succession of sparks at the distance of three inches or more; and some, five feet in diameter, have given strong sparks at the distance of more than twelve inches.

Mr. Adams, philosophical instrument maker to his majesty, prepares machines of this kind with plates formed from a composition of two parts of shell-lac, and one of Venice turpentine, without any glass plate.

The action of these plates depends on a principle discovered and illustrated by the experiments of Franklin, Canton, Wilcke, and Epinus, that an excited electric repels the electricity of another body, brought within its sphere of action, and gives it a contrary electricity. Thus the plate A, touched by a conductor, whilst in contact with the plate B, electrified negatively, will acquire an additional quantity of the electric fluid from the conductor; but if it were in contact with a plate electrified positively, it would part with its electricity to the conductor connected with it. See an account of several curious experiments made with this machine, by Mr. Henly, and Mr. Cavallo, and Dr. Ingenhousz, in the Phil. Trans. vol. lxvi. part ii. p. 513. vol. lxvii. part i. p. 116, &c. and part ii. p. 389, &c. and vol. lxviii. part ii. p. 1027, and p. 1049. See *Vindicating* ELECTRICITY.

ELECTRUM is sometimes used for AMBER.

ELECTRUM more frequently signifies a mixed metal, of great value among the ancients.

ELECTRUM *minerale* is a name given by some chemists to a metallic mass formed of tin and copper, and martial regulus of antimony, to which gold is sometimes added. The mass is powdered, and detonated with nitre and charcoal, to a kind of *scoria*; then powdered whilst hot, and digested in spirit of wine; whence a tincture of a red colour is obtained, which is effected a deobstruent.

ELECTUARY, in *Pharmacy*, a form of medicine, composed of powders and other ingredients, incorporated with some conserve, honey, or syrup; to be divided into doses, like boluses, when taken.

Vossius observes, that all the remedies prescribed for the sick, as well as the confections taken by way of regale, were called by the Greeks ΜΑΝΤΗΜΑΤΑ, and ΜΟΧΤΗΣΕΣ, of the verb ΜΑΣΣΩ, *I lick*; whence, says he, was formed the Latin *electuarium*, and afterwards *electuarium*. This conjecture he supports from the laws of Sicily, where it is ordained, that *electuaries*, syrups, and other remedies, be prepared after the legal manner. The Bollandists, who relate this etymology, seem to confirm it. Act. Sanct. Mart. tom. ii. p. 131.

Electuaries are either soft, or solid; and of each kind, some are alterative, others corroborative, others purgative, &c. The *soft* are of the consistence of honey, and may consist of three ounces of powder to a pound of honey, or conserve, and syrup.

The purgatives are usually of the soft kind; but the corroborative only admit of 1, or 1½ ounce of powders, to five or six ounces of conserve, with a proper quantity of syrup.

Among the soft *electuaries* of the shops are reckoned lenitive *electuary*, Venice treacle, mithridate, the confection of hamech, that of alkermes, the catholicon, diapruneum, diaphœnicum, Galen's hiera picra, &c. which see explained under their respective articles.

Among the solid *electuaries*, are reckoned those of carthamum, rose juice, violet juice, &c. M. Lemery reckons up about a hundred and twenty sorts of *electuaries*, and beside these there is an infinite variety in extemporaneous prescriptions.

To make *electuaries* in perfection, where a syrup is the basis of the composition, as in the *electuary* of sassafras, and the like, the syrup should be prepared in a close vessel, that none of the virtues of the ingredient may be lost; the powders, to be afterwards added to this, should be fresh, and very finely sifted; the gums, when there are any in the composition, should be well cleansed, and dissolved in their proper menstruums; and the whole must be reduced to a smooth mass, of such a consistence, as will neither be subject to candy nor ferment.

Where syrups are used only to bring *electuaries* into form,

care must be taken that they are not boiled too high; for that will subject them to candy in the *electuary*, and spoil the whole, as the being too low boiled, or thin, will leave them subject to ferment in hot weather, and afterwards grow sour, so as to change, invert, or destroy the nature of the medicine.

Electuaries made of the pulp of fruits, are less disposed to keep than others, on account of the great tendency these subjects have to ferment and putrefy. Hence a lenitive *electuary* can never keep long, especially if made too thin.

Just the contrary of this is the case, however, with the capital *electuaries*, as Venice treacle, mithridate, and the like; for these require to be some time made, that the ingredients may digest or ripen, as it were, and grow mellow together, as the gums and spices that are in that composition keep it from any decay, provided the honey doth not candy, which some prevent by using it uncleansed; and if these *electuaries* prove too dry, they are to be moistened with Canary wine, and thus they improve by keeping. This, however, is not the case with the diascordium, which loses of its astringency as the ingredients become mellow together; and this is much better made up with fugar of roles, or syrup of diacodium, instead of honey. Shaw's Lectures, p. 209.

The way of powdering and sifting the ingredients for *electuaries* is liable to lose their finer and lighter parts, in form of a light duft, and that of grinding them in a horse-mill has the same inconvenience, with the additional one of a great quantity of stony matter mixing itself from the mill-stones with the powder. The best way would certainly be, by means of two iron rollers moving against one another in a close box, as in the making of chocolate, and to grind together all the ingredients, with the honey and wine, and bringing all at once to a proper consistence. Perhaps, indeed, a much better way than all, though a very troublesome one, would be to get out the full virtues of all the ingredients separately, in the form of extracts and essential oils, &c. and mix these with a proper quantity of honey, and, by this means, to concentrate the medicine, so that it might be given agreeably in very small doses.

ELECTUARY *e scammonio*, a new name given, in the London Pharmacopœia, to the composition commonly called *electuarium cathareticum*. The composition is also so much altered, that instead of an ounce, a dram and a half is now a common dose. The prescription for it is this: take scammony, an ounce and a half; cloves and ginger, of each six drams; oil of caraway seeds, half a dram; honey, half a pound; mix all into an *electuary*. Pemberton's Lond. Disp. p. 336.

ELECTUARY *for the Dysentery, for the Epilepsy, for the Gonorrhœa, for the Piles, for the Palsy, for the Rheumatism.* See DYSENTERY, EPILEPSY, GONORRHŒA, HÆMORRHOIDS, PALSY, and RHEUMATISM.

ELEEMOSYNA *Corn-arum*, or *pro Aratris*, or *Aratri*, in our *Ancient Customs*, a penny which king Ethelred ordered to be paid for every plough in England, towards the support of the poor. Sometimes it is also called *eleemosyna regis*, because first appointed by the king.

ELEEMOSYNÆ is also used for the possessions belonging to churches. See ALMS, and FRANK *Almoign*.

ELEEMOSYNARIA. See AMBRY.

ELEEMOSYNARIUS, in our *Old Writers*, is used for the almoner, or peculiar officer who received the eleemosynary rents and gifts, and distributed them to pious and charitable uses. There was such an officer in all religious houses. The bishops also used to have their almoners, as now the king has. Linn. Provinc. lib. i. tit. 12. See also Du Cange, Gloss. Lat.

ELEEMOSYNARY *Corporations*. See CORPORATIONS.

ELEGANCE, ELEGANCY, from *elego*, *I chuse*, denotes a manner of doing, or saying things politely, agreeably, and with choice.

With choice, so as to rise above the common manners; politely, so as to strike people of delicate taste; and agreeably, so as to diffuse a relish which gratifies every body.

ELEGANCE, in *Oratory*, is one of the three parts of general ELOCUTION, and respects the purity and perspicuity of the language. By the former a discourse is rendered correct, and by the latter intelligible; and both extend to the selection of single words, as well as to their construction in sentences. See PURITY, and PERSPICUITY.

Poetical *elegancies*, *elegancies poetice*, are of service to scholars in making their verses; by being too regular in the grammatical construction, we lose certain licences, wherein the *elegance* of language consists. *Elegance*, though irregular, is better than regularity without *elegance*.

The *elegance* of a painting is not founded on the correctness of the design, as appears in Raphael, and the antique. It is most felt in works otherwise careless and inaccurate; as in Correggio, where, in spite of all the defects as to justness of design, there is an *elegance* even in the manner of the design itself, as well as in the turn of the attitudes, &c.

The *elegance* of a design is a manner which embellishes and heightens objects, either as to their form, or colour, or both; without destroying or perverting the truth.

ELEGIA, in *History*, a name given, by some authors, to the *wands sceptoria*, or *writing reed*, common in Greece and Italy.

ELEGIAC, in the *Latin Poetry*, something that belongs to *elegy*.

Elegiac verses, Ἐλεγεῖα, are alternately hexameter and pentameter.

Quintilian esteems Tibullus the chief of the *elegiac* poets; but the younger Pliny gives the preference to Propertius. They have each of them reason on their side; and one might make a third choice, as just as either of them. See ELEGY.

ELEGIT, in *Law*, a judicial writ, given by the statute Weſtm. 2. 13 *Edw.* I. cap. 18. which lies for him who has recovered debt or damages, or upon a recognizance in any court, against one not able in his goods to satisfy, and directed to the sheriff, commanding him to make delivery of half the party's lands, and all his goods, oxen and beasts for the plough excepted.

This writ should be sued out within a year and a day after the judgment.

The creditor shall hold the moiety of the said land so delivered to him, till his whole debt and damages are satisfied; and during that time he is tenant by *elegit*. See TENANT.

ELEGY, Ἔλεγος, a mournful, and plaintive kind of poem. Voſſius, after Didymus, derives the term from ἐ, ἐ, λέγειν, *to say alas!*

The first inventor of the *elegy* is not known: some say it was one Theocles of Naxus, or, according to others, of Eretria, who, in the heat of his phrensy, first produced this kind of composition. But there is no wonder that we are at this time in the dark as to the matter; Horace assures us it was a point not settled among the grammarians even in his time, who the author was.

Quis tamen exiguos elegos emiserit auctor,
Grammatici certant, & adhuc sub judice lis est.

The chief writers of *elegy* among the Greeks, are Callimachus, Parthenius, and Euphorion; and among the Latins, Ovid, Catullus, Tibullus, and Propertius.

The Flemish have distinguished themselves among the moderns for this kind of Latin verse. The *elegies* of Bidermann, Grotius, and especially Sedronius and Vallius, seem worthy of the purest antiquity. The countess de la Suze has distinguished herself for *elegies* in the French tongue.

In the English, we have nothing considerable of the *elegiac* kind, but what we have in Milton. The English and French *elegies* are chiefly in Alexandrine verses.

In process of time, *elegy* degenerated from its original intention; and not only matters of grief, but also joy, wishes, prayers, expostulations, reproaches, and almost every subject, were admitted into *elegy*.

The office of *elegy* is well delivered by M. Boileau:

La plaintive elegie en long habits de deuil,
Spoir, les cheveux epars, gemit sur un cercueil:
Elle peint des amans la joye, & la triſteſſe:
Flatte, menace, irrite, appaiſe une maîtreſſe.

In mourning weeds ſad *elegy* appears,
Her hair diſhevell'd, and her eyes in tears:
Her theme, the lover's joys, but more his pains;
By turns ſhe ſings, ſooths, threatens, and complains.

The diction of *elegy* ought to be clean, easy, perspicuous, expreſſive of the manners, tender, and pathetic; not oppreſſed with sentences, points, &c. No apoſtrophes are allowed; and the ſenſe ought to be generally cloſed in every diſtich, or two lines: at leaſt, in Latin compoſitions.

ELEMENTARY, ſomething that relates to the principles or *elements* of bodies.

The *elements* of a body are alſo called the *elementary principles* thereof. See PRINCIPLE.

The whole ſpace, included within the concave, or orbit of the moon, is called the *elementary region*, as being the ſeat, or ſphere, of the four vulgar *elements*, and the bodies compounded thereof.

The author of the Comte de Gabalis gives the name *elementary people* to a kind of beings who are ſuppoſed to inhabit the *elements*, and are only known by what they call the *philoſophers*, ex *ſages*. According to theſe perſons, the *element* of *fire* is inhabited by ſalamanders; *water*, that is, the

the sea and rivers, by nymphs, or oridans; *earth* by gnomes and gnomides; and *air* by sylphs and sylphides.

ELEMENTARY *Air, Fire, Geometry, &c.* See the substantives.

ELEMENTS, in *Physics*, the first principles or ingredients of things, wherein all bodies are compounded; and into which they are all resolvable.

Elements are conceived as the most simple, homogeneous parts or corpuscles; of an assemblage and mixture whereof, all the bodies we see, consist.

Authors generally talk wildly, and inconsistently, of the *elements*, and confound them with the *principles* of things, yet there is great difference; and we find by experience, that all things cannot indifferently be made of all; that stone, for instance, and marble are not convertible into flesh, nor are fit to nourish or augment an animal body: it seems to follow, that all the variety of bodies could never arise from the first simple combination of the two principles, matter and form; but only some infinitely simple beings, or corpuscles, which being variously intermixed, might constitute all other bodies. Now those most simple of all beings, thus formed of the first determination and concretion of principles, are what the philosophers properly call *elements*; so that *elements* and principles have this difference between them, that a principle, as matter, is a kind of incomplete nature; but an *element* is a perfect or complete one.

Hence it follows, that there must, of necessity, be more *elements* than one; since otherwise all things would be equally simple, and there would be no such thing as a compound in nature. Most of the ancients, not aware of this, confound *element* with principle; by which means the *elements* are sometimes represented as corruptible, and sometimes as incorruptible. The retainers to incorruptible *elements*, mean precisely by *element* what we mean by the first matter. In effect, their *elements* are their atoms or corpuscles, which are supposed indivisible, incorruptible, &c.

Democritus is held to have been the first author of this tenet; which accordingly is adhered to by Epicurus, and many of their descendants, the Epicurean and corpuscular philosophers. Among those who hold the *elements* corruptible, some will only have one, and some several. Of the former, the principal are Heraclitus, who held fire; Anaximenes, air; Thales Milesius, water; and Hesiod, earth; as the only *elements*. Hesiod is followed by Bernardin, Telesius; and Thales, by many of the chemists.

Among those who admit several corruptible *elements*, the principal are the Peripatetics; who, after their master Aristotle, contend for four *elements*; viz. fire, air, water, and earth. Aristotle took the notion from Hippocrates; Hippocrates from Pythagoras; and Pythagoras from Ocellus Lucanus, who seems to be the first author of the dogma.

The Cartesians only admit three *elements*; which they pretend are all that could arise from the first division of matter. See CARTESIAN *Philosophy*.

Our great sir Isaac Newton considers the primary *elements* of bodies on the atomical system; thus, all things considered, it seems probable, that God in the beginning formed matter in solid, massive, hard, impenetrable, moveable particles, of such sizes and figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and that these primitive particles, being solids, are incomparably harder than any porous bodies compounded of them; even so very hard as never to wear out; no ordinary power being able to divide what God made one in the first creation. While the particles remain entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break in pieces, the nature of things, depending on them, would be changed; water and earth, composed of old worn particles, and fragments of particles, would not be of the same nature and texture now, with water and earth composed of entire particles in the beginning. And, therefore, that things may be lasting, the changes of corporeal things are to be placed only in the various separations, and new associations and motions, of those permanent particles; compound bodies being apt to break not in the midst of solid particles, but where those particles are laid together, and only touch in a few points. It seems to him likewise, that these particles have not only a *vis inertiæ*, with the passive laws of motion resulting therefrom, but are also moved by certain active principles; such as is gravity, and that which causes fermentation, and the cohesion of bodies. See COHESION, EARTH, FERMENTATION, GRAVITY, and PRINCIPLE.

ELEMENTS, in *Chemistry*, are the principles, or component parts, of natural bodies, into which they are resolvable by fire, &c.

The effect of chemistry is, to analyse or resolve bodies into their *elements*.

The chemical *elements* are divided into *active* and *passive*. The chemists are somewhat divided as to their *elements*. Some to the vulgar Peripatetic *elements*, water, which they call phlegm; and earth, which they call *caput mortuum*, add three more; viz. salt, sulphur, and mercury. Salt they hold the principle of taste; and sulphur, of smell and inflammability: as to mercury, which they also call spirit, some hold it the principle of colours, but others deny this; and, in effect, they agree in nothing, but that it is the most subtil and spirituous part.

Other chemists consider fire, air, water, and earth, as the only proper *elements*, or simple bodies; alleging, that by the most complete and accurate analyses which have been made, nothing has been ever ultimately produced but from one or more of these four substances, according to the nature of the decompsed bodies; and that they really act as such in all chemical operations. Macquer.

The *elements* of fossils are, 1. Mercury, as the base. 2. Sulphur, as the coagulator, or binder. 3. Salt. 4. Earth. The *elements* of metals, are sulphur and mercury alone; mercury as the base, or matter, and sulphur as the binder, or cement. The *elements* of fossil salts are an acid spirit, and insipid earth. The *elements* of earths are an *oil*, a little acid salt, and a calx. The *elements* of sulphurs are an acid spirit, an oil, and an earthy or metallic matter. Boerhaave.

But, after all, it must be added, that there is no assigning any precise number of chemical *elements*; some bodies yielding more, and others less. And even these very *elements* themselves are reducible, by a farther process, into other *elements*. Thus, by repeated distillations of wine, we successively get a spirit of wine, a vapid water, a subacid water, a more acid water, oil, bitter yellow spirit, and a *caput mortuum*, which is resoluble into earth, oil, &c. Now, are these so many several *elements*? Add, that what they account an *element*, now that it is separated, is very different from what it was when it existed in the mixt; as appears hence, that upon remixing all the *elements* a body is resolved into, the mixture will bear no resemblance to the first body.

In effect, these *elements* seem rather to be produced by the fire, than separated by it. Beside, that they are convertible, or at least resolvable, into one another. Thus spirit of wine is found to yield an acid, an oil, and a water; and salts yield either an acid, or an alkali, with phlegm. What makes the notion of the chemical *elements* still more precarious, is, that a pot-herb, and a poisonous herb, shall sometimes yield *elements* perfectly alike; more so, than the same plant analysed at two different times. M. Homberg has considered the difficulties charged on *elements* with great attention.

The result of numerous experiments made to ascertain the matter is, that the four principles, salt, oil, water, and earth, are always found in all plants, in what manner soever analysed; that these principles are more or less volatile, or fixed, according to the different manners of analysing; that this difference arises, not only from the different force of fire, but also from the fermentation of the mixed, preceding the analysis; that a vehement fire rendering different *elements* equally volatile, confounds them in the analysis; that the fire evaporates, and absolutely loses several parts; and that to have the *elements* as pure as may be, only fermentation, and a gentle fire, must be used.

ELEMENTS are also used, figuratively, for the grounds and principles of arts and sciences.

Thus we say, letters are the *elements* of speech: he does not know the first *elements* of grammar.

The ELEMENTS of mathematics have been delivered by several authors in their courses, systems, &c. The first work of this kind is that of Peter Herigon, in Latin and French, published in 1664, in ten tomes; wherein are contained the *elements* of Euclid, Euclid's Data, Apollonius Pergæus, &c. with the *elements* of arithmetic, algebra, trigonometry, architecture, geography, navigation, optics, spherics, astronomy, music, perspective, &c. The work is remarkable for this, that, throughout, a kind of real and universal characters are used; so that the demonstrations may be understood by such as only remember the characters, without any dependence on language or words at all.

Since Herigon, the *elements* of the several parts of mathematics have been laid down by others, particularly the Jesuit Schottus, in his Cursus Mathematicus, in 1674. Sir Jonas Moor, in his New System of Mathematics, in 1681; De Chales, in 1674; Ozanam, in his Cours de Mathematique, in 1699; and, above all, Christ. Wolfius, in his Elementa Matheseos Universæ, in two vols. 4to. the first published in 1713, and the second in 1715; a work

a work never enough to be commended. There has been another edition of this excellent work published at Geneva, in five volumes in quarto; the first volume in 1732, the second in 1733, the third in 1735, the fourth in 1738, and the fifth in 1741.

The *Elements* of Euclid are the first and best system of geometry. We have abundance of editions and comments on the fifteen books of Euclid's *Elements*. Orontius Finæus first published the first six books in 1530, with notes, to explain Euclid's sense. The like did Peletarius in 1557. Nic. Tartaglia made a comment on all the fifteen books about the same time, with the addition of some things of his own; and the like did Fran. Flussates Candalla, a noble Frenchman, in the year 1578, with considerable additions, as to the comparison and inscriptions of solid bodies; which work was afterwards republished, with a prolix comment, by Clavius, whose edition has since been reprinted, at various places and times.

Dr. Gregory published an edition of all Euclid's works, including his *Elements*, in Greek and Latin, in 1703, fol. But as the whole fifteen books do not seem necessary, especially for young mathematicians, some authors have chosen only the first six, with the eleventh and twelfth at most. It would be endless to relate the several editions hereof; there is a French one of De Chales, and a Latin one of And. Tacquet; the best edition of the former of which, is that of Paris in 1709, by Ozanam; and of the latter, that of Cambridge in 1703, by Mr. Whiston. Mr. T. Simpson's *Elements* of Geometry is an excellent compendium of this kind: and Dr. Simpson of Glasgow published in 1756, a Latin edition of the six first, and eleventh and twelfth books of Euclid, with notes.

ELEMENTS, in the *Higher Geometry*, are the infinitely small parts, or differentials, of a right line, curve, surface, or solid. Thus, (*Tab. Analysis, fig.* 18.) the small space PM*mp*, formed by the two ordinates PM, *pm* infinitely near each other, and the arc Mm of the curve, is the *element* of the space APM, Pp is the *element* of the abscisse AP, Mm that of the curve AM, &c. See DIFFERENTIAL, FLUXION, &c.

ELEMENTS, in *Astronomy*, are those principles deduced from astronomical observations and calculations, and those fundamental numbers, which are employed in the constructions of tables of the planetary motions. Thus, the *elements* of the theory of the sun, or rather of the earth, are his mean motion and eccentricity, and the motion of the aphelia. The *elements* of the theory of the moon are its mean motion, that of its node and apogee, its eccentricity, the inclination of its orbit to the plane of the ecliptic, &c.

ELEMI, or ELEMY, in *Pharmacy*, a pellucid resin, of a whitish colour, intermixed with yellowish particles, and often much of the colour and consistence of wax; of a pretty brisk bitter, though not disagreeable taste; and a smell somewhat like that of fennel.

It is usually called *gum elemi*, though very improperly, inasmuch as it takes fire readily enough, and dissolves in oleaginous liquors, which are the characters of a resin, not a gum. It totally dissolves in rectified spirit of wine; and in distillation with water, fifteen ounces of gum yield one ounce of essential oil. It flows from incisions made in the trunk and large branches of a large and tall tree, of the olive kind, growing in Ethiopia, and Arabia Felix. It is also found in Apulia, a province in the kingdom of Naples.

Pomet in his History, and Lemery in his Dictionary of Drugs, describe *elemi* as a white resin, bordering on green, odoriferous, and brought from Ethiopia, in cakes of two or three pounds a-piece, and usually wrapped up in the leaves of the Indian cane.

It is excellent in diseases of the head; and is proper to digest, resolve, and suppurate. It is held a kind of natural balsam; and is sovereign in the cure of all sorts of wounds.

One of the best officinal digestives, commonly called the ointment or liniment of Arceus, consists of six parts of the *elemi*, five or six of turpentine, and twelve of lard, or a mixture of lard and suet melted together.

The true *gum elemi* is that above described; but there are several spurious sorts, some natural, and others factitious, frequently sold for it.

The factitious, or counterfeit, is usually made of resin washed in oil of aspic; though the ill smell, and white colour of this might easily discover the fraud. The natural gums, obtruded for *elemi*, are,

1. A gum brought from the American islands, in cags of different weights, covered up with the leaves of a plant unknown in Europe.

The second may be taken for common resin, but for its smell, which is somewhat sweeter, and more aromatic.

The third is of an ash colour, bordering on brown, brought over in large pieces, and very dry and friable.

Pomet does not take any of these for different genuine gums, but rather supposes them to be originally *elemi*, only impure, and coarse, since melted down, and made up by the fire.

ELENCHUS, *in Antiquity*, a kind of ear-rings set with large pearls.

ELENCHUS, Ἔλεγχος, in *Logic*, by the Latins called *argumentum*, and *inquisitio*, is a vicious or fallacious argument, which deceives under the appearance of a truth; the same with what is otherwise called *sophism*.

ELEOCARPUS, in *Botany*. See ELÆOCARPUS.

ELEOSACCHARUM, rather ELÆOSACCHARUM, ἐλαιοσάκχαρον, in *Pharmacy*, a mixture of sugar with a distilled oil, in order to bring it to mix with some aqueous fluid for present use.

Grind an ounce of fine and dry loaf sugar to an impalpable powder, in a glass mortar, with a glass pestle; then add to it, by degrees, a dram of any essential oil, or half a dram, if the oil be very tenacious: continue rubbing them together till the oil be thoroughly mixed, and drank into the sugar. The oil, in this operation, usually diffuses a fragrance to a great distance; wherefore to prevent the loss of its finer parts, the operation should be performed as quick as possible, and the mortar covered, and the pestle surrounded by a clean linen cloth; and if a little quantity of the white of an egg be added in the grinding, and mixed in with the sugar and oil, the oil thus becomes more easily miscible, but the mixture will not keep so long without growing rancid. The sugar, which is a pure soap, or a true essential oily salt, divides the glutinous tenacity of the oil, interposes itself between the principles thereof, unites them closely with itself, and makes an extemporaneous soap, which may be commodiously diluted with water for medicinal uses. Though this mixture is not so perfect as an actual soap, or true essential salt, yet it suffices for use; nor is there reason to apprehend any inconvenience from the sugar in this preparation; for sugar is unjustly said to be unwholsome, as there are no solid proofs extant of this; on the contrary, it is a wonderful salt that perfectly mixes with water, and ferments therewith into wine, and yet, what is surprising, it appears oleaginous and perfectly inflammable in the fire, whence it is known to consist of oil and salt.

If these *eleosaccharums* be carefully prepared, and put up in clean dry glasses, exactly closed with glass stoppers, they may be preserved perfect a long time; and in this manner very effectual medicines may be easily carried from place to place, and, upon occasion, directly used upon a journey, by mixing a small quantity of them in a glass of wine. An *eleosaccharum*, or mixture of the same nature, at least, might be also made, by mixing an essential oil with a fixed alkaline salt, by grinding, by which means also a kind of soap is obtained; but this, thus mixed, destroys the grateful properties of the essential oils, and change their natural taste and odours. Such mixtures also would presently resolve in the air, and thence be easily altered; but, by the method with sugar, the physicians may always readily prepare a medicine rich in virtues. If the *eleosaccharum* of mint, for instance, be dissolved in mint water, then strengthened with an addition of spirit of mint, and the mixture sweetened with syrup of mint, the whole virtues of the plant will be thus obtained. Boerh. Chem. part ii. p. 100.

ELEOSELINUM, in *Botany*, a name by which some authors have called the paludapium or smallage. Ger. Emac. Ind. 2.

ELEPHANT, *Elephas*, in the Linnæan system of *Zoology*, the name of a distinct genus of the *bruta*, in the class of *mammalia*. The characters which make the distinction of this genus, are, that the *elephant* has no *dentes incisores*, or cutting-teeth, and that the *canini*, or dog-teeth, of the upper-jaw are very long; that it has a very long, flexible proboscis, and almost naked body. The proboscis is a long cartilaginous trunk, formed of many rings, and terminated with a small moveable hook. This trunk serves the animal instead of a hand, to convey any thing into the mouth, and to defend it from its enemies; the nostrils are at the end of the proboscis, which is the organ of feeling and of smell, both which senses the *elephant* possesses in a very exquisite degree. Besides the proboscis, the *elephant* has two large tushes projecting from the upper-jaw, and bending a little upwards. The largest of those imported into England are seven feet long, and weigh a hundred and fifty-two pounds each. The eyes of this animal are small, its ears large and pendulous; the back is arched; the lips are thick and clumsy; the neck short; the feet are round and undivided, but terminated at their margins with five small hoofs; the knees are flexible; it has two paps on the breast; the tail resembles that of a hog, and the skin is very thick and callous, and, when dressed, impenetrable

y a musket-ball, of a dusky colour, and has a few scattered hairs on it. The *elephant* is the largest of all land animals, and is said to be twelve or even fifteen feet high. See *Tab. Quadrupeds, fig.* 2.

Elephants are found both in Asia and Africa; but those of Asia are the largest, though they are much more numerous in Africa. They are said to go a year with young, and to bring forth one at a time; they live, according to Tavernier, in his Voyages, a hundred and twenty or a hundred and thirty years, and are thirty years before they attain their full growth. The *elephant*, notwithstanding its enormous size, is exceedingly swift; and so strong, that, after being tamed, they have been employed to carry pieces of artillery, small towers, with a number of people in them, and also vast loads. The Indians have from very early times employed them in their wars; Porus, as Quintus Curtius informs us, lib. viii. cap. 41 opposed the passage of Alexander over the Hydaspes, with eighty-five of these animals; and M. de Buffon apprehends, that some of the *elephants* taken by that monarch, and afterwards transported into Greece, were employed by Pyrrhus against the Romans. The *elephant*, notwithstanding its size and strength, is the most docile and tractable of all animals. Naturalists relate many instances in which they have discovered a sensibility of benefits, a resentment of injuries, a modesty, and an ambition, of a very surprising degree.

The figure of an *elephant* is found on many of the ancient medals. Julius Cæsar, towards the end of the Roman republic, being prohibited from putting the figure of his own head on their coin, substituted that of the *elephant*: thus flattering his ambition by a very trivial circumstance; as in the Punic language, *Cæsar* signified an *elephant*. The *elephant* was afterwards used as a symbol of sovereign power, of eternity, and of piety towards the Deity.

ELEPHANTS, *taming of*. The method of taking and taming this creature, in the island of Ceylon, is as follows: the natives pitch upon a proper place for a warren, or park, which is broad at the entrance, and grows narrower further in, till, at the end, it is so narrow that an *elephant* cannot turn himself, and it runs on of this narrowness so far, that twenty *elephants* may stand in it one behind another. When the inclosure of this warren is finished, all the people of the neighbouring places assemble, and make a circumference round the woods, where they know there are *elephants*, which takes in, perhaps, sixty miles. The men now stand at twenty-five yards distance, and kindle fires between them, and make all the noise they can, by shouting, blowing horns, beating drums, and the like, and, by degrees, approach nearer and nearer the warren. The *elephants* run from the fires and noise, and consequently can go no where but towards the warren; the men, who every where surround them, except on the warren side, follow upon them in this manner, till they come together, and make a ring, and the *elephants* are driven into the inclosure. When these creatures perceive that they are thus taken, they make resistance, and shun turn upon the men, but there are always near the warren fences of poles, lying flat upon the ground, which the hunters need only raise up, and they keep in the prey, so that they can neither escape, nor injure them; they then purfue the *elephants* with firebrands, and drive them into the narrow part where they cannot turn.

They are, from this place, taken one by one, and led to the ſtable, each between two tame *elephants* bred for that purpoſe, the points of whoſe long teeth are cut; and theſe, if the wild *elephant* be troubleſome, will lay hold of his trunk with theirs, and beat him with their teeth. A man, ſitting upon each of the tame *elephants*, directs them by a ſtaff with a hook at the end, with which he occaſionally touches their heads, and orders them as he pleaſes, without bridle, or any other furniture. When they are brought into the ſtable, they are led between two poſts, with ſtakes put athwart before their breaſts, and under their bellies, and are ſo tied that they cannot ſtir, nor lie down upon the ground; for, if permitted to lie down, they would become ſorrowful, and refuſe to eat, and would die. They are here fed with the trunks of plantains, a food they much delight in, and when they have been kept thus about ſix weeks, they become tame enough for ſale. If not ſold at that time, they feed them about ſix weeks longer in the ſtable with cocoa leaves, and they are, at the end of that time, perfectly tame as a ſpaniel, and will eat graſs with the oxen in the fields. Phil. Tranſ. N° 277. § 1.

The *elephants* of Ceylon have been ſo long hunted, that they now know man for their mortal enemy, and ſeldom fail to riſe upon and kill him wherever they meet him; but if a man lie upon the ground, and pretend to be dead, they never meddle with him. Several people have in this iſland, lain aſleep while *elephants* paſſed by them, and ſome have only pretended ſleep, and a perfect ſtillneſs has always been found to preſerve them, even though the creature came up to examine them.

ELEPHANT, *Elephas*, gives the denomination to an ancient and honourable military order, conferred by the kings of Denmark on none but perſons of the higheſt quality, and extraordinary merit.

It is called the *order of the Elephant*, from its badge, which is an *elephant*, with a caſtle on its back, ſet with diamonds, and hung on a watery ſky-coloured ribband, like the George in England.

There are different ſentiments as to the origin and inſtitution of this order; the firſt is that of Monſtrelus and Hoepingius, who attribute it to Chriſtian IV. who was elected king in 1588. The ſecond, that of Selden and Imhof, who derive it from Frederic II. elected in 1542. Gregorio Leti goes back as far as Frederic I. who reigned about the year 1530. Bernard Boholdius will have king John to be the author, who began to reign in 1478. Anſelmius, Roſſæus, and Loccher, hold it to have had its riſe under Chriſtian I. father of Frederic I. Laſtly, Vorgius, Becman, and Torcherodius, maintain Canutus VI. to have been the firſt inſtitutor; and the occaſion thereof to have been the croiſades. This prince, according to the chronology of Sleaning, reigned towards the cloſe of the twelfth century, from the year 1168, to 1191. This, at leaſt, we are certain of, that the order was ſubſiſting in the year 1494; there being a painting ſtill extant, come that year by count Reinden, a knight of this order. And we have even authentic evidences of the marquiſs of Mantua's being created knight of the ſame order by Chriſtian I. in 1474. There are bulls of pope Pius II. and Sextus IV. confirming the ſtatutes of the order, authoriſing the holding of aſſemblies, or chapters, in the chapel of Roeſchild, and ſetting the privileges of the knights.

The order was at firſt called the *order of St. Mary, orde S. Mariæ*; though it ſeems to have had the appellation of the *elephant* as early as Chriſtian I. when the figure of an *elephant* is often ſtruck on his coins, medals, &c.

The manner of its inſtitution is thus related: king Canutus having ſent a fleet againſt the Saracens in 1189, which took Zidunia and Ptolemais, a gentleman among the Daniſh croiſers killed an *elephant*; in memory of which extraordinary accident the order was erected. This account is rendered the more probable by this; that it is referred to an æra, when nothing was more common than to take the ſpoils of a vanquiſhed enemy for armories or cognizances; and accordingly, ſome of the principal arms of the like kind now on foot, e. gr. the lions of the Low-Countries, had their riſe at the time of the croiſades, as is ſhewn by Heuterius and Hoepingius; which circumſtances greatly corroborate the opinion of thoſe who aſcribe the order to king Canutus.

To the collar of the order hangs an *elephant*, with a ſilver turret on its back; and underneath the *elephant*, an image of the Holy Virgin, incircled with rays. See the abbot Juſtiniani, Hiſt. de tutti gl'Ord. Milit. e Caval. tom. ii. cap. 72.

The chapel of Roeſchild was founded by Chriſtian I. for the aſſemblies or chapters of this order to be held in. It was firſt called the *Chapel of the Three Kings*, *Capella Trium Regum*; afterwards Frederic I. gave it the name of the *Royal Chapel*.

The order was reſtored by Frederic II. who created abundance of knights at the ceremony of his coronation, which is the only time when the Daniſh kings make any knights of the *Elephant*. Chriſtian V. augmented and enriched it very conſiderably. In the year 1694, a grand chapter of the order was held at Frederickſburg, in the chapel of the knights, wherein ſix German princes were admitted into the order.

We have a multitude of writings on the ſubject of this order, whereof that of Janus Torcherodius may ſerve for all the reſt; it is the braſeſt, moſt ample, and learned. It was publiſhed at Copenhagen in 1705. under the title of Brevis ium Equeſtre, ſeu de Illuſtriſſimo, & Inclytiſſimo Ordine Elephantino, &c.

ELEPHANT'S *bones*. Many teeth and bones of animals have been found in a foſſile ſtate, both in Siberia, and on the banks of the Ohio, in North America. The French academicians, on comparing ſome of theſe with the bones of real *elephants*, determined, that they belonged to the ſame ſpecies of animal: but Dr. Hunter has diſcovered, on a more accurate examination, that they are very different from thoſe of the *elephant*, and belong to another animal. The tuſks of the true *elephant* have a ſlight lateral bend; but thoſe brought from America have a larger twiſt, or ſpiral curve, towards the ſmaller end: the grinders of the latter are made like

those of a carnivorous animal, being furnished with a double row of high and conic processes, as if designed to masticate, and not to grind its food; whereas, those of the *elephant* are flat, and ribbed transversly on their surface; besides, the thigh bone is of a very disproportionate thickness to that of the *elephant*, and has some other anatomical variations. And though the American tusks, when cut and polished by the workmen in ivory, did not differ in texture and appearance from the true ivory, Dr Hunter concludes, that genuine ivory must be the production of two different animals, and not of the *elephant* alone; and that the animal to which these bones belonged may be the supposed *elephant* or mammouth of Siberia, and other parts of the world, which is yet unknown. Phil. Transf. vol. lviii. art. 5.

ELEPHANT's *foot*, in *Botany*. See ELEPHANTOPUS.

ELEPHANT's *head*, in *Botany*, a species of the *rhinanthus*. See LOUSEWORT.

ELEPHANT-*caterpillar*, a name given by some authors to a species of insects, commonly known in Ireland by the name of *Connaught-worm*, and supposed to be poisonous to cattle which feed on it. See *Connaught* WORM.

ELEPHANT's *nose*, or *elephant's snout*, as it is called by the Dutch, is a species of the scus or needle-fish, caught in the East Indies, fo called from the resemblance of its snout to the trunk of an *elephant*. It is a very singular species, the lower jaw running out into a very long and sharp-pointed spine: it is round-bodied, and beautifully variegated with spots, and has on each side a green line running from head to tail. It is caught in salt-waters. Ray's Ichthyogr. app. p. 4.

ELEPHANT, *water*. See HIPPOPOTAMUS.

ELEPHANTIASIS, in *Medicine*, a kind of leprosy, called also *lepra Arabum*, in contradistinction to the *lepra Graecorum*, which is another disease.

The *elephantiasis* is thus denominated, because those seized therewith have their arms and legs big swollen, and tumorous; the skin bloated, yet rough to the touch, and all wrinkled and rugose like the skin of an elephant.

The *elephantiasis* is a disease unknown in our parts of the world, at least in these days. Some authors call it *leontiasis*, and others *satyriasis*. The Greeks call it ελεφαντιασις, and sometimes ελεφας, *elephant*; also ελεφαντια and ελεφαντιωσις. The *elephantiasis Graecorum*, or *lepra Arabum*, is described by Deodatus as a contagious disease, infecting the body with a variety of evils.

In the *lepra Arabum*, the skin is beset with a dry scabby crust: as in the former case the salts, being left destitute of their humidity, are not so active, and therefore affect only the cuticle; in the latter case these salts, with their vehicle, attenuating faster than they can be evaporated through the pores of the skin (being still in *fluors*, and so more caustic) corrode deeper, and eat not only the cuticle, but the excretory vessels, and surface of the skin itself, which thereby exudes a liquor somewhat thicker than usual; which, when the thinnest and most aqueous parts are evaporated, are condensed into that crust or scab, which is the distinguishing character of this disease.

Galen defines the *lepra*, an effusion of thick disorderly blood, that corrupts the whole habit of the body. Avicenna calls it an *universal cancer*.

The *lepra* always begins within-side, a long time before it appears without-side. It was frequent in Europe in the tenth and eleventh centuries, but seems at present almost extinct: unless we allow the venereal disease to be the same with the *lepra*, as was the opinion, among many others, of the learned Pitcairn; and has been lately endeavoured to be proved by Mr. Becket, in a discourse expressly on the subject, in the Philosophical Transactions.

The symptoms of the ancient *lepra*, as laid down by Galen, Aretæus, Pontanus, Ægineta, Cardan, Varanda, Gordon, Pharæus, and others, are as follow: the patient's voice is hoarse, and comes rather through the nose than the mouth; the blood is full of little white shining bodies, like grains of millet, which, upon filtration, separate themselves from it; the serum is feculous, and destitute of its natural humidity, insomuch, that salt applied to it does not dissolve; it is so dry, that vinegar poured on it boils; and is so strongly bound together, by little imperceptible threads, that calcined lead thrown into it swims. The face resembles a coal half extinct, unctuous, shining, and bloated, with frequent hard knobs, green at bottom, and white at top. The hair is short, still, and brinded, and not to be torn off without bringing away some of the rotten flesh to which it adheres: if it grows again, either on the head or chin, it is always white. Athwart the forehead run large wrinkles or furrows, from one temple to the other; the eyes are red, and inflamed, and shine like those of a cat; the ears swollen, and red, eaten with ulcers towards the bottom, and encompassed with little glands; the nese sunk, because of the rotting of the cartilage; the tongue dry, and black, swollen, ulcerated, divided into furrows, and spotted with grains of white; the lips covered with ulcers, that die and revive on each other, and with white spots or scales, like a fish; it is rough, and insensible, and when cut, instead of blood, yields a serious liquor. It arrives in time to such a degree of insensibility, that the wrist, feet, or even the large toes, may be pierced with a needle, without the patient's feeling any pain. At last the nose, fingers, toes, and private members, fall off entire; and by a deadness similar to each of them, anticipate that of the person. It is added, that the body is so hot, that a fresh apple held in the hand for an hour, will be dried and wrinkled as if exposed to the sun for a week.

Matthew Prior says, that in Christendom there were fifteen thousand hospitals for lepers; but since, many having been discontinued for two hundred years, the revenues of those hospitals were abused, and persons feigned themselves lepers, to be entitled to the provision, which occasioned their regulation in some countries, and their entire suppression in others.

In France, they were united to the order of the religious of St. Lazarus and Mount Carmel in 1664, and the administration of them given to the knights of that order. See LAZARUS. In England they have been converted to other purposes.

Formerly the causes of lepers were committed to the ecclesiastical tribunals; and it was prohibited to prosecute the leper before a lay-judge, in regard they were under the protection of the church, which separated them from the rest of the people, by a ceremony still to be seen in the ancient rituals.

As to the cure, that which proved effectual in these southern countries, is found to fail among us, where the strongest medicaments, and the most powerful mercurials are necessary. Bathing is judged to be of good use in the *lepra*. Dogs and hares are said to be subject to this disease. Among the Indians, a white man is despised, this passing with them for the mark of a leper.

The *elephantiasis* of Madeira appears at first in the form of tubercles on any or all parts of the body; in time they ulcerate; if they happen on the beard or eye-brows, the hairs fall off, but not on the head. The legs swell, and are hard, white scales cover them, and fissures appear in different parts, though in some instances the legs are emaciated, and full of ulcers. Many other very disagreeable symptoms are observed in different patients. None are observed to receive this disorder from other by contact; but the children of the diseased are generally subject to it. The bark, attended with a proper embrocation and blistering, have effected a cure of this disorder, after mercurials and antimonials have failed. London Med. Transf. vol. i. p. 23, &c. See LEPROSY.

ELEPHANTINE, something that relates to, or partakes of the qualities of elephants.

The term is chiefly applied to certain books of the ancient Romans, wherein were recorded the transactions of the emperors, and the proceedings, acts, &c. of the senate. This we learn from Pollio and Vopiscus, in the Life of the Emperor Tacitus, where he observes, that in the sixth press of the Ulpian library, was kept one of these *libri elephantini*; wherein, for a long course of time, were written down the decrees and edicts of the senate.

In some of these books, were registered all the acts and proceedings of the senate, and the magistrates of Rome; in others, the proceedings and events in the provinces, the armies, &c. There were about thirty-five large volumes of them, as many as there were tribes. In them were likewise contained the births, and classes of the citizens, with the musters, and all things belonging to the census. They were renewed every five years with the censors, and were all anciently kept in the *ærarium*, or public treasury, in the temple of Saturn.

Vigenere, and several others, believe these books to have been called *elephantini*, by reason of their enormous bulk: but Lindel, on the seventeenth chapter of the eleventh book of Aulus Gellius, gives us a different etymology; and assures us, they were called *elephantini*, because composed of ivory leaves or tablets, which every body knows is a production of the elephant. See DIPTYCHA.

ELEPHANTOPUS, of ελεφας, and πους, *foot*, *elephant's foot*, in *Botany*, a genus of the *syngenesia polygamia æqualis* class. Its characters are these: the flowers are collected in one common involucrum, each containing four or five florets, which are tubulous, and divided into five equal parts; they have five very short hairy stamina: in the bottom is situated an oval germen, which afterwards becomes a single compressed seed, crowned with bristles, and sitting on a naked placenta.

There

There are two species, natives of the East and West Indies.

ELEPHAS, see ELEPHANT.

ELEPHARI, in the *Materia Medica*, a name used by some authors for the common small cardamom of the shops.

ELEVATIO, *in Prosody*, the same as *arsis*. See ARSIS.

ELEVATION, the altitude or height of any thing. See ALTITUDE.

The word is formed from *elevare*, *to raise* or *lift up*.

ELEVATION *of a star*, or other point, in the sphere, is an arch of the vertical circle, intercepted between such star, or other point, and the horizon.

Hence, as the meridian is a vertical circle, a meridian altitude or *elevation*, i. e. the *elevation* of a point in the meridian, is an arch of the meridian, intercepted between that point and the horizon.

ELEVATION *of the pole*, denotes the altitude of the pole above the horizon of any place, or an arch of the meridian, intercepted between the pole and the horizon.

Thus, in *Tab. Aft. anonym. fig.* 4. AQ being supposed the equator, HR the horizon, HZPN the meridian, and P the pole; PR is the *elevation of the pole*.

In which sense *elevation* stands opposed to *depression* or depth. See DEPRESSION.

The *elevation of the pole* is always equal to the latitude of the place; that is, the arch of the meridian intercepted between the pole and the horizon, is always equal to the the arch of the same meridian, intercepted between the equator and the zenith. Thus, the north pole is *elevated* 51° 32′ above the horizon of London; and there is the same distance, or number of degrees, between London and the equator; so that London is likewise in 51° 32′ of northern latitude.

To observe *the elevation of the pole* of any place, see POLE and LATITUDE.

ELEVATION *of the equator*, is an arch of the meridian, less than a quadrant, intercepted between the equator and the horizon of the place.

Thus AQ, as before representing the equator, HR the horizon, P the pole, and HZPN the meridian; HA is the *elevation of the equator*. See EQUATOR.

The *elevations of the equator*, and of the pole, together, are always equal to a quadrant; consequently, the greater the *elevation* of the pole, the less the *elevation of the equator*, and *vice versa*.

Thus, in the figure just cited, PA is supposed by the construction a quadrant; and HA+AP+PR a semicircle; consequently, HA+PR is a quadrant.

ELEVATION *of the equator, to find the*. Find the *elevation* of the pole, after the manner hereafter directed, under the article POLE.

Subtract the *elevation* found from a quadrant, or 90°; what remains is the *elevation of the equator*. Thus, the *elevation* of the pole 51° 32′, being subtracted from 90°, leaves the *elevation of the equator* 38° 28′.

ELEVATION, in *Architecture*, denotes a draught or description of the principal face or side of a building, called also its *upright* or *orthography*. See ORTHOGRAPHY.

ELEVATION is also used in some writers of perspective for the scenography, or perspective representation of the whole body or building. See SCENOGRAPHY.

ELEVATION, in the *Romish religion*, is applied to that part of the mass wherein the priest holds or raises the host, with the cup above his head, for the people to adore it, after having first consecrated and adored it himself.

Whilst the priest officiates at mass, a bell is rung at the *elevation*, to apprize the people to call their eyes upon their new-formed Saviour and adore him.

St. Lewis decreed, that they should fall on their knees at the *elevation*, in imitation of certain religious whom he does not name. The Chartreux, and the religious de la Trappe, still observe this ceremony of prostrating themselves at the *elevation*.

ELEVATION, *angle of*, in *Mechanics*, is the angle ARB (*Tab.* III, *Mechanics*, *fig.* 47.) comprehended between the line of direction of a projectile AB, and the horizontal line AB. See PROJECTILE and ANGLE.

ELEVATION *of a cannon* or *mortar-piece*, is the angle which the chase of the piece, or the axis of the hollow cylinder, makes with the plane of the horizon.

ELEVATOR, ELEVATORIUM, in *Surgery*, an instrument used to raise up bones, as those in fractures of the skull, when beaten or crushed in with blows, or the like.

There are dented *elevators*, and *elevators* with three feet, called *elevators triplades*. See *Tab.* III. *Surgery*, *fig.* 35. The feet A, A, A, of this instrument may be brought nearer or farther from each other, as occasion requires. These feet are applied to the sound parts of the head, and the screw BC is made to lay hold of the depressed part of the cranium, by turning round the handle DD, after a small hole has been made in the middle of it with a sharp awl; then, by turning the screw EE, the TREPAN at B is raised by degrees, and with it the depressed part of the cranium. The method of doing this is represented in *fig.* 36. See TREPANNING and *fig.* 37. The *elevator* made lever-wise, is a new invention; its use is in drawing teeth. One extremity of it is flat, to rest on the gum at the bottom of the tooth; and the other hooked, like one of the branches of a pelican, to lay hold of the tooth. In *Tab.* II. *Surgery*, *fig.* 22. is represented the *elevator* for the cornea, in the operation of couching.

ELEVATOR, in *Anatomy*, is a name common to several muscles, which do the office of raising or lifting up the parts they belong to, or equal import with the ATTOLLENS and LEVATOR. Such are the

ELEVATOR *alæ nasi*, a muscle, or pair of muscles of the nose, of a pyramidal figure, very narrow, though fleshy at its origination, on the fourth bone of the upper jaw, and very broad and thin at its termination on the side of the ala nasi. Its action is to pull the ala upwards, and turn it outwards. See *Tab. Anat.* (*Myol.*) *fig.* 1. *lit.* o.

It is called by Winslow the *transversalis* or *inferior nasi*, and by Albinus the *compressor nasi*. Cowperus has described it under the name of the *parvus nasi musculus*, and Fallopius under that of *musculus alius cornutus nasi*, and Riolanus by that of *alius externus nasi*.

ELEVATOR *auris*, or *attollens auriculam*, is in reality no more than a part of the muscle of the scalp, with some fleshy fibres in it, as it descends over the temporal muscles to the upper part of the concha. Its action is scarce visible; the auricles being hardly perceived in men to have ordinarily any motion at all. See *Tab. Anat.* (*Myol.*) *fig.* 6. *n.* 3. *fig.* 1. *n.* 13.

ELEVATOR *humeri*, in *Anatomy*, a name given by some authors to a muscle, now generally known under the name of the DELTOIDES.

ELEVATOR *labiorum communis*, a muscle of the lips, arising from the fourth bone of the upper jaw, and terminating at the angle of the lips, under the zygomaticus. See *Tab. Anat.* (*Myol.*) *fig.* 1. *n.* 4.

ELEVATOR *labii inferioris*, is a muscle that arises from the second bone of the under jaw, below the incisores. It descends, and passes under the zygomaticus, and is inserted into the under lip.

This, assisted by a small, but strong pair of muscles, arising from the gum of the dentes incisivi, and descending directly, is inserted into the lower part of the skin of the chin, and serves to pull the skin of the chin upwards, and consequently to thrust up the lip.

ELEVATOR *labii superioris*, arises from the upper part of the second bone of the upper jaw, and descending obliquely, is inserted into the upper lip, above the dentes incisivi: it draws up the lip. See *Tab. Anat.* (*Myol.*) *fig.* 1. *n.* 3. and *n.* 5.

ELEVATOR *oculi*, one of the musculi recti of the eye, serving to draw it upwards. See RECTUS and EYE.

ELEVE, a term purely French, though of late used also in our language. Literally it signifies a disciple or scholar, bred up under any one, being formed from the Italian, *allievo*, *an apprentice or novice*.

It was first used by the French writers, in speaking of painters; such a painter was an *eleve* of Da Vinci, of Raphael, &c. From painting, it came to be applied to such as studied or learned any other art under a master.

In the Royal Academy of Sciences, there were twenty *eleves*; and in that of inscriptions, ten *eleves*. The *eleves* are to act in concert with the pensionaries. See ACADEMY.

The denomination *eleve*, however, has been since suppressed, and that of *adjoint* substituted in its room; because every body did not know the sense affixed to it by the academy: and now the pensionary academists have not, as formerly, each of them an *eleve*; but the *eleves* are become *adjoints*, or associates of the academy.

ELEUSINIA, in *Antiquity*, the mysteries of the goddess Ceres, or the religious ceremonies performed to her honour; thus called from *Eleusis*, a maritime town of the Athenians, wherein was a temple of that goddess, famous for the celebration of these mysteries. See CERIALIA.

Some writers call the city where the *Eleusinia* were celebrated, *Eleusinia* or *Eleusis*: Harpocration confirms this orthography, in deriving its name from *Eleusinus*, a son of Mercury; to which opinion Pausanias likewise adheres, in his Attics. Others, who write it *Elusis*, *Advent*, suppose it thus called, because Ceres, after running over the world in search of her daughter, stopped here, and put an end to her pursuit. Diodorus Siculus, lib. v. will have the name *Eleusis* to have been given this city, as a monument to posterity, that corn, and the art of cultivating it, were brought from abroad into Attica.

The *Eleusinia* were the most solemn and sacred ceremonies in use among the Greeks; for which reason they were

were called *mysteries*, by way of eminence. They are said to have been instituted by Ceres herself, at *Eleusis*, in memory of the zeal and affection wherewith the Athenians received her.

This is the account Isocrates gives in his Panegyric: but Diodorus Siculus assures us, lib. v. that the *Eleusinia* were instituted by the Athenians, in gratitude to Ceres, for having instructed them to lead a less barbarous and rustic life: yet the same author, in the first book of his Bibliotheca, relates the thing in another manner.

A great drought, says he, having occasioned a miserable famine throughout all Greece; Egypt, which had that year reaped a most plentiful harvest, bestowed part of the fruits thereof upon the Athenians. It was Erechtheus that brought this extraordinary supply of corn; in commemoration of which benefaction, Erechtheus was created king of Athens, who instituted the Athenians in these mysteries, and the manner of celebrating them.

This account comes near to what we are told by Herodotus and Pausanias, viz. that the Greeks acquired the knowlege of their gods and their religion from the Egyptians.

Theodoret, lib. i. Græcanic. Affect. writes that it was Orpheus, not Erechtheus, who made this establishment, and who instituted for Ceres what the Egyptians practiced for Isis; which sentiment is confirmed by the scholiast on the Alcestis of Euripides.

Eleusis, the city where these mysteries were celebrated, was so jealous of the glory thereof, that, when reduced, to the last extremity by the Athenians, it would not surrender but on this condition, that the *Eleusinia* should not be taken away; though these were no religious ceremonies peculiar to the town, but were held common to all Greece.

The matter of these mysteries, as related by Arnobius, and Lactantius, was an institution, or representation, of what mythologists teach of Ceres. They lasted several days; during which, the people ran about with burning torches in their hands; sacrificed abundance of victims, not only to Ceres, but also to Jupiter; made libations from two vessels, one of them to the east, and the other to the west; marched in pomp to *Eleusis*, making pauses from time to time, wherein they sung hymns, and sacrificed victims; and this they performed, not only in going to *Eleusis*, but in returning back to Athens. For the rest, they were obliged to keep it an inviolable secret: and the law condemned to death any one who should dare divulge their mysteries. Tertullian, in his book against the Valentinians, relates, that the figure thereof was in the *Eleusinia*, and which was so expressly prohibited to be made public, as that of a man's privy parts. Theodoret, Arnobius, and Clemens Alexandrinus, likewise make mention of it; but they say it was the figure of a woman's privities.

The day after the feast, the senate assembled at *Eleusis*, apparently to examine whether every thing had been managed according to order.

There were two kinds of *Eleusinia*, the *greater*, and the *less*; those we have hitherto been speaking of were the greater.

The *lesser* were instituted in favour of Hercules; for that hero desiring to be initiated into the former, and the Athenians not being able to gratify him therein, because the law prohibited any stranger being admitted; being loth, however, to give him an absolute denial, they instituted new *Eleusinia*, in which he assisted. The greater were held in the month Boedromion, which answered to our August; and the lesser in the month Anthesterion, which happened in our January. People were only brought to partake of these ceremonies by degrees; at first, they were to be purified; then admitted to the lesser *Eleusinia*; and at last initiated in the greater. Those, who were yet only at the lesser, were called *mystæ*; and those admitted to the greater, *epoptæ*, or *ephori*, i. e. *inspectors*. They were usually to undergo a probation of five years, before they passed from the lesser to the greater. Sometimes, indeed, they were contented with a single year; immediately after which, they were admitted to the most secret religious parts of the ceremony. Meursius has an express treatise on the *Eleusinia*, where most of these points are proved.

ELEUTHERIUS, *Ἐλευθέριος*, in *Antiquity*, a Greek word, signifying *liberator*, or *deliverer*. It was used by the Greeks as a surname, or epithet of Jupiter, given him on occasion of his having gained them the victory over Mardonius, general of the Persians, and killed, as they say, 300,000 men of his army; and, by that means, delivered them from the danger they were in of being brought under the Persian yoke.

The word is formed from *ἐλεύθερος*, *free*.

There were also feasts solemnised on this occasion, in honour of Jupiter *Eleutherius*, and called *Eleutheria*, which were held every five years, with races of armed men, &c. The Scholiast on Pindar, Olymp. Od. [illegible] were celebrated at Platea, the place where the victory was obtained.

The Samians had another festival of this name, in honour of the god of Love; and slaves, which had obtained their liberty, were wont to keep a stated holiday in remembrance of the happy day on which they were made free. Potter's Archæol. Græc. lib. iii. cap. [illegible] p. 388.

ELFS, or ELVES, called also *Fairies*, the name of [illegible] honoured among the Saxons, with a kind of [illegible] called *Alfsblot*.

ELF-*arrows*, a name given by the people of [illegible] Scotland to certain flint weapons which they find [illegible] which have been in use before tools and weapons of iron were used there. It is not only in Scotland that these are found, but in America, and many other places also. They are styled by some *ceraunia*, and *thunder-bolts*, and are supposed to have fallen from the clouds in storms of thunder; others, not less erroneously, suppose them to be natural fossils; but their true origin is from the workmanship of man, out of common flints, and other stones. Woodward's Nat. Foss. ii. p. 52.

ELHANNE, in *Botany*, a name given by some authors to the ligustrum Ægyptiacum, or [illegible]

ELICA *poshum*, in *Natural History*, a [illegible] by the people of the East Indies to [illegible] found very frequently in that [illegible] given internally, after calcination, in [illegible] vers.

ELICE, or HELICE, in *Botany*, a name by which [illegible] cient Greek writers have sometimes called the willow, though its more general name among them is *hea*. Hesychius gives many instances of the willow being called *helice*.

ELICRYSUM, in *Botany*. See CUDWEED.

ELICIT, or ELICITED, in *Ethics*, is applied to an act of the will, immediately produced by, and of the will, and received within the same.

Such are willing, nilling, loving, hating, &c. These acts are denominated *elicit*, [illegible] being before in the power of the will, they are now brought forth into act. But they are so far intrinsic, that some authors consider them as the will itself; and deny they ought to be distinguished from it, any more than light is to be distinguished from the sun.

ELIDRION, a word used by the early writers in *Medicine*, in several different senses; some using it as the name of mastic, others of raphanine, and others of crude mercury. Some of the former writers have also made it express a certain mixed metal, composed of three parts; one silver, another brass, and the third gold.

ELIGENDO *Virilario*. See VIRILARIO.

ELIGIBILITY, in the Romish *Canon Law*. A *bull of eligibility* is a bull granted by the pope, to certain person, to qualify them to be chosen, or invested with an office, or dignity, whereof they were before incapable, by reason of want of age, birth, or the like.

The word is formed of the Latin *eligere*, *to choose*; whence the word *eligibilitas*, &c.

In several churches in Germany, a person, who is not of the chapter, cannot be elected bishop, without a bull of *eligibility*.

ELIGII *morbus*, a name given by some medical writers to a fistula.

ELIGMA, a name given by Nicolaus, Myrepsius, and some other authors, to that form of medicine now called a *linctus*, or *lambative*.

ELIQUATION, in *Metallurgy*, is a separation of the different parts of mixed bodies, by the different degrees of fire required to melt them. When the mixture of ores, or of metallic mixtures is such, that while one part of them melts in the fire, the other, more refractory and difficult of fusion, remains still solid: the first, when the mass is placed in a mild fire, flows out of the interstices of the other, and is thus separated from it. The perfection of this operation requires a different fluidity of the parts that constitute the mass. Lead, for instance, melts into one mass with copper, by a strong fire, whereas these metals cannot dissolve each other in a moderate one; but if the mass, composed of both these, then blended together, is afterwards exposed to a mild fire on an inclined plane, the lead alone melts, the copper becoming only brittle and spongy, and remaining in its solid form, even when the lead has run out of it. This separation, however, is not so perfectly made, but that there ever remains some lead in the copper, and some small part of the copper is also carried away with the lead; wherefore, it is necessary for this experiment, that the metals are not mixed in too minute proportions; for

for if one thousandth part only of lead were to be mixed with copper, or the same small proportion of copper with the lead, the separation, by *elixation*, could not be effected.

It is generally necessary also, in order to make this operation succeed, to add ingredients that are capable either of destroying the force by which the different parts cohere together, or of procuring an easier flux of the metals; for the mixture of the other metals will not be separated like those of copper and lead, without the admixture of other substances. For instance, gold, silver, and copper, melted together, and perfectly blended by that means with one another, remain in the same state in any degree of fire: to make the *elixation* of the gold and silver, therefore, out of such a mixture, the same additions must be used as in the operation of *precipitation by sulfur*. Sulphur added, in this case, does indeed dispose the copper to abandon the gold and silver; but if these two, as it most commonly happens, are mixed in a very small quantity with a very large one of copper, then you cannot yet obtain the separation of them; for beside, that very small quantities are no more to be separated [illegible] than in the former instance of copper and [illegible] copper fluid by almost the [illegible] or fire, in which the silver and gold are [illegible] quantity of lead must therefore [illegible] by the help of that addition, [illegible] ded in a gentle fire, and the [illegible] em.

[illegible] by lead, and by fusion, are both [illegible] for, by means of them, [illegible] and silver may, without any [illegible] from a large mass of other [illegible] has not hitherto been found possible to [illegible] with advantage by any other method. Cramer, Art. Aff. 188.

ELIRE, see CONGE d'elire.

ELISION, in *Grammar*, the cutting off, or suppressing of a vowel at the end of a word, for the sake of sound or measure.

Elisions, excepting in poetry, are but little known in English; in Latin, French, &c. they are frequent, and consist mostly in suppressions of the final *a*, *e*, and *i*: as in *Phœbus amus ante omnes. Si sol virtutem spectat*, &c.

In writing, *elisions* are often marked by an apostrophe; as *vous n'aurez point sa bonté pour regretter. Ramène-le-t-il pour semer. Pendrai-je pour m'en aller*, &c. *Cette espérance, fut cette; l'homme*, for *le homme*.

In the pronunciation we make frequent *elisions*, but do not mark them in writing: thus we write *risque il*, but pronounce *risqu'il*. So the French pronounce *un' ame*, but write *une ame*. In effect, they never mark any *elisions* but at the end of the monosyllables *je, me, le, te, ce, que*, and *de*. They never elide the *s*, nor *n*, nor *t*, but in the conjunctions *si* before *il*; not *a* but in *la*.

In poetry, the syllable, where there is a vowel elided, is never reckoned; and great care is taken to avoid the clashing of syllables where there is no *elision*, this making what they call a *hiatus* or *chasm*.

Some reckon the *ecthlipsis* under the head of *elisions*; as in *monstrum, horrendum, ingens*, &c. See ECTHLIPSIS.

ELIXATION, in *Pharmacy*, &c. the infusing, seething, or boiling of any medicine in a proper liquor, gently, and for a considerable time; amounting to what in the dressing of meat, we call *braising*.

The word is formed from the Latin, *lixare, to boil*, or *boil in water*.

The liquor ordinarily used in *elixation*, is spring or river water; though on some occasions they use spirit, milk, whey, beer or the like.

The ordinary purpose of *elixation* is, to extract the virtue out of the medicine, and impart it to the liquor; though it is sometimes also used to free the parts of animals, plants, &c. of their crudities, as well as to soften and make them tender; to take away from foods or medicaments any disagreeable taste, or other ill quality; to separate the earthy, or grosser parts; and for other intentions.

Decoction is also a sort of *elixation*. See DECOCTION.

ELIXIR, in *Medicine*, a compound tincture, or essence, drawn from a mixture of several ingredients, by infusing them in a proper menstruum.

Menage derives the word from the Arabic, *eksir*, properly signifying *fracture*, because *elixirs* have the force of breaking diseases: others, more naturally, derive it from the Arabic, *alquifre*, an artificial extraction of some essence; others from the Greek, ξαινω, *xaino*, *I draw*, q. d. an extract of the oil, which is the essential part of mixts; others from the Greek verb, ωνεω, *oneo*, *I help or assist*, of because the great succours we receive from *elixirs*.

An *elixir* is properly a strong spirituous liquor or juice, to be taken inwardly, containing the purest, and most efficacious parts of several mixed bodies, communicated to it by infusion and maceration.

Quincy defines it, a strong infusion in some menstruum, whereby the ingredients themselves are almost dissolved, and a liquor thus acquired of a thicker consistence than an ordinary tincture.

Boerhaave considers an *elixir* as a compound magistery, i. e. a compound of various bodies, changed after the same manner as a single body in a magistery.

Spirits drawn from vegetables, i. e. the strong or spirituous waters of vegetables are usually the basis of *elixirs*, and the menstruum, or dissolvent, whereby the essence of the other ingredients is drawn or separated. Spirit of wine is the best and most commodious menstruum of all.

Quacks abuse the term *elixir*, and apply it to abundance of simple extracts, or tinctures, only to put them off at the highest price. Some authors, for *elixir*, use the word *quintessence*.

ELIXIR *album*, a name given in the late London dispensatory to the medicine commonly known by the name of *elixir proprietatis*, which is there also ordered to be made in the following manner: take tincture of myrrh a quart, powder of aloes, and fine saffron, of each three ounces; digest them a due time, and then press off the tincture, and filter it for use. Pemberton's London Disp. p. 284.

ELIXIR *peregrinum*, a name given in the late London dispensatory to the medicine commonly known by the name of *elixir salutis*, which is there ordered to be made thus:

Take flowers of benjamin, and strained opium, of each a dram; camphire, two scruples; essential oil of anifeeds, half a dram; rectified spirit of wine, a quart: digest all together a proper time, and then strain off the spirit. This allays tickling coughs, relieves difficult breathing, and is useful in many disorders of children, particularly in the hooping-cough. The dose for an adult is from 50 to 100 drops. Pemberton's Lond. Disp. 284.

ELIXIR, *sacred*, is prepared by infusing ten drams of rhubarb, cut small; six drops of Socotine aloes, in powder; and half an ounce of lesser cardamom seeds, in two pints of French brandy, for two or three days, and then straining the liquid. This useful stomachic purge may be taken from one ounce to an ounce and a half. Buchan's Dom. Med. p. 746.

ELIXIR, *salutis*. Take of sena leaves, cleared of their stalks, four ounces; of guaiacum chips, of dried eleecampane-root, of the seed of anise, caraway, coriander, and of liquorice-root, of each two ounces; of stoned raisins, eight ounces; and steep these ingredients in four quarts of French brandy, cold, for four days; and then strain out the spirit for use. Dufty's *elixir* is said to be little more than this. James. See TINCTURE *Sena*.

ELIXIR, *stomachic*, is prepared by boiling two ounces of gentian-root, one ounce of Curaffoa oranges, and half an ounce of Virginia snake-root, and infusing them for three or four days in two pints of French brandy, and then straining out the *elixir*. This is an elegant stomachic bitter. A small glass, twice a day, relieves in flatulencies, indigestion, want of appetite, and similar complaints. A large dose also relieves the gout in the stomach. Buchan.

ELIXIR *of vitriol, acid*, is prepared by gradually mixing one pint of the *aromatic* TINCTURE with three ounces of oil of vitriol; and after the fæces have subsided, filtring the *elixir* through paper in a glass funnel. This is an excellent medicine for hysteric and hypochondriac patients, afflicted with flatulencies, arising from a relaxation or debility of the stomach and intestines. It is to be taken on an empty stomach, twice or thrice a day, in a glass of wine or water, or of any bitter infusion; and the dose may be from 10 to 40 drops. Buchan.

ELIXIR *proprietatis*, is a remedy first invented by Paracelsus, compofed of aloes, myrrh, and saffron; the tincture or essence whereof is drawn, by putting them to dissolve or digest with spirit of sulphur: some add spirit of wine to spirit of sulphur.

Crollius takes this *elixir* to be the balm or balsam of the ancients; adding, that it contains all the virtues of the natural balm. It comforts and fortifies the heart and stomach, purifies the blood, and promotes perspiration.

ELIXIR, among the *Alchymists*, is used for the philosophers stone, or the powder of projection; and sometimes for an universal medicine, which will cure all diseases, called by way of excellence, the *grand elixir*.

Those two things most alchymists take to coincide; so that what will make gold, they think, will cure all *diseases*. See PHILOSOPHERS *stone*.

The notion of a *grand elixir* is of a long standing.

ELIXIS, a name given by some of the *Old Writers* to that form of medicine now called ELECTUS.

ELK, in *Zoology*, a species of the *cervus* or STAG. The *alce*, or elk, is an animal so sufficiently described by the ancients, that it is evident they either knew very little of it, or else different writers have described different animals under this name. Pliny tells us, that the *alce* resembles the horse; but that it is distinguished by the length of the neck, and largeness of its ears. Solinus says that it resembles the cattle; and both authors add, that its upper lip is so large, that it cannot feed without moving backwards. Philo, from report, affirms the same of the *gnesios*, an animal of Scandinavia. Some have compared the *alce* to the goat, and others to the stag. Some say it was of a dusky yellowish colour; but Cæsar, in his Commentaries, expresses it as variegated with spots. Pausanias tells us, that it resembles the stag kind, but was like the camel in the length of its neck. In the Linnæan system the *alce*, as a species of the *cervus palea*, with beams having three branches on the upper and broad palmated one side of which is plain, and the summit furnished with several sharp snags. It has no brow antlers under the throat it has a small excrescence.

The *elk* is a wild beast, found in the forests of Muscovy, Swedeland and Prussia, but more abundantly in Canada, and most parts of North America.

It is about the size and figure of a mule, only its snout is sharper, its tail shorter, its feet cloven; and that it bears a large carriage, or horn, like that of a deer. That anatomized, in the Royal Academy of Sciences, was five feet seven in its body, its head is brown, about the length or that of a goat; and being very erect, is used for measures twenty-one inches long, and four broad; and its tail not above two inches; its neck short and thick, its skin strong and hard, though thin; so that, according to Lahontan, it will turn a musket ball: its flesh very delicious, especially that of the female: the tongues, especially, are much commended, and are often brought to us from Russia; and the ligaments of its joints extremely strong, which has occasioned some authors to say, that its legs had no joints at all; and that it was thus made at its ease at sitting on the ice, to save it from the wolves. It neither runs, nor bounds, but its pace is almost equal to the swiftest running of a deer. *See Tab.* II. *Quadrupeds*, No. 10.

The hunting of the *elk*, is one of the principal and most agreeable employments of the savages of Canada, Acadia, &c. They choose a time when the snow is on the ground, in which the beast is apt to sink and stick. When they have killed enough with their firearms to feed the several days, they slay them, and send the skins to the manufacturers, who dress them in oil, like the buffalo skin.

The savages likewise take care to cut off the left hind-foot of each beast, especially if it be a female; the hoof of which foot is the applauded remedy for the falling-sickness.

Authors tell us, that to catch the *elk*, the northern people watch the occasion when it falls down of the epilepsy, which it frequently does; and that they lay hold of it before it can recover strength enough to put its left foot in its mouth, which cures it immediately.

And hence it is, that the notion of its virtue in the cure of that disease had its rise. The Germans call it *elend*, that is, misery, because of the misery it is reduced to, in falling so often into the epilepsy, though it has its remedy always about it; which but gives reason to suspect, that the virtue ascribed to it is fanciful.

Accordingly, Olaus Magnus says, it is the outer hoof of the right foot that the *elk* puts in its ear to cure the epilepsy; which being impossible, it should seem as if Olaus only spoke of it by way of jest.

He says, that the blows which the *elk* deals are so strong, that with its hinder feet it will even break the trees; and with its fore-feet pierce the hunters through and through; though they are inoffensive animals, unless they are wounded, or in the rutting season.

Pomet gives us the marks to distinguish the genuine *elk* stones; but as their virtue is very equivocal, not to say imaginary, there is no great harm in being deceived.

ELK, in *Ornithology*, a name by which many have called the *tetrao tetrix*, or wild fowl. *See* GROUSE.

ELKE, is mentioned in our *Statutes*, as a kind of yew to make bows of. 32 Hen. VIII. cap. 9.

ELL, *ulna*, a measure, which obtains, under different denominations, in most countries.

The *ell* is the standard, or measure, wherein cloths, linens, silks, &c. are usually measured, or estimated, and weighed, in good measure, to the yard of England, the canna of Italy, the vara of Spain, the palm of Sicily, &c.

Statutes will have the *ell* to be the space contained between the two hands when stretched forth; but common custom makes it only the cubit.

The *ell*, which occurs most frequently in English books, is the *ell English*, which contains three feet nine inches, or one yard one quarter English measure; the *ell Flemish* contains twenty-seven inches, or three quarters of a yard; so that the *ell* English is to the *ell* Flemish as five to three.

M. Ricard, in his Treatise of Commerce, reduces the *ells* of one hundred of Amsterdam are equal to ninety-eight three-quarters of Brabant, Antwerp, and Brussels; to fifty-eight and an half of England and France; to an hundred and twenty of Hamburgh, Frankfort, Leipsic, and Cologne; to an hundred and twenty-five of Breslaw; to an hundred and ten of Bergen and Drontheim; and an hundred and seventeen of Stockholm.

ELLIPOMACROSTYLA, in *Natural History*, the name of a genus of crystals. The word is derived from the Greek ἔλλειψις *imperfect*, μακρὸς *long*, and στύλος *a column*, and expresses an imperfect crystal, with a long column. The perfect figure of crystal being a column terminated by a pyramid at each end; those which want this character are esteemed imperfect; and accordingly the bodies of this genus are defined to be imperfect crystals, with single pyramids, one end of their column being affixed to some solid body, and composed of thin and slender hexangular columns, terminated by hexangular pyramids. Of this genus there are several species. *See Tab. of Fossils, Class* 3.

ELLIPOPACHYSTYLA, in *Natural History*, the name of a genus of crystal. The word is derived from the Greek ἔλλειψις, *imperfect*, παχὺς *thick*, and στύλος, *a column*, and expresses a crystal of the imperfect kind, with a thick column. The bodies of this genus are crystals, composed of an hexangular column, considerably thick and short, and affixed irregularly at one end to some solid body, and terminated at the other by an hexangular pyramid. Of this genus there are only two known species. *See Tab. of Fossils, Class* 3.

ELLIPSIS, in *Geometry*, one of the conic sections, popularly called an *oval*.

The word is formed from the Greek, ἔλλειψις, *defficiency*, a denomination which the ancient Greek geometricians gave this figure, because, among other properties, this is one, that the squares of the ordinates are less than, or defective of, the rectangles under the parameters and abscisses.

The *ellipsis*, defined from its form, is a regular continued curve line, including a space that is longer than broad, wherein are two points equally distant from the two extremes of the length, from which, two right lines being drawn to any point, assumed at pleasure in the *ellipsis*, their sum is equal to the length of the *ellipsis*.

Thus, in the *ellipsis* AEBDM. *fig.* (*Tab. Conics. fig.* 21.) the lines F *a* and f *a* drawn from the two points F and f, equally distant from the two extremes A and B, are equal to AB.

Or, taking the *ellipsis* as geometricians frequently do, for the space contained or included within this curve line, it is defined a figure, contained under one single oblong line, and having two unequal axes or diameters, AB and DE. The greater axis of the *ellipsis*, or the right line representing the length of the *ellipsis* AB, or of the space included by the *ellipsis*, is called the *transverse axis* or *diameter*; and the lesser axis, representing the breadth of the *ellipsis* DE, the *conjugate* or *second axis*. The two axes always bisect each other at right angles. *See* AXIS.

The two axes are the two greatest diameters of the *ellipsis*; but there are an infinity of other different diameters. *See* DIAMETER, &c.

ELLIPSIS, *characters of an*, in the point C, wherein the two axes intersect. *See* CENTRE.

The two points F and f, in the greater axis, equally distant from the extremes thereof A and B, are called the *foci*, or *umbilici of the ellipsis*; from which two lines, drawn to the circumference of the *ellipsis*, as already observed, are equal to the greater axis. *See* FOCUS.

The *ellipsis*, considering it as a conic section, that is, as a curve, arising from the section of the cone, is best defined from its genesis, or the manner of its production, thus: an *ellipsis* is a curve line, produced by cutting the right cone A B C (*fig.* 21. N° 2.) by a plane, passing through both its sides, in such manner, as that the axis of the section DE meets with the diameter of the base AB produced to F; or so that the cutting plane be not parallel to the base, in which case the section will produce a circle; or again, by cutting an oblique cone in any oblique direction, so that the cutting plane be not subcontrary to the base.

O, passing it from one of its known properties assumed, as *ellipse* is a curve line, wherein the square of the semi-ordinate PM is to the rectangle of the segments of the axis AP and PB, as the parameter is to the axis.

Thus, if $AB=a$, the parameter $=b$, $PM=y$, $AP=x$, then will $b:a::ax-x^2:y^2=ax-x^2$; consequently $a:b::ax-x^2:y^2$. See CONIC *Sections*.

Hence, $1.\ y^2=bx-\frac{bx^2}{a}$, or $x=\frac{a}{2}\pm\sqrt{\frac{aa}{4}-\frac{ay^2}{b}}$; that is, the square of the semi-ordinate is equal to the rectangle of the parameter into the abscifs, abating another rectangle of the same abscifs into a fourth proportional to the axis, parameter, and abscifs.

2. *Ellipfis, to find the axis, parameter, and femi-ordinate of an.* The parameter, abscifs, and femi-ordinate, in an *ellipfis*, being given, the axis is found, by making $1.\ b:y::\frac{y^2}{b}$, then $2.\ x-\frac{y^2}{b}\left(=\frac{bx-y^2}{b}=\frac{z^2}{b}\right)::1:z$.

3. The axis AB, the abscifs AP (*fig.* 22.) and the femi-ordinate PM, being given, the parameter AG is thus found: make AL=PM; and from A, through M, draw the right line AL. To it erect a perpendicular LI; then, from AP, PM: AL: LI $=\frac{y^2}{x}$. Produce PM to O, fo that PO=LI $=\frac{y^2}{x}$; and from B, through O, draw the right line BG. To A erect a perpendicular GA, which will be a fourth proportional to PB, PO, or LI, and $\frac{ay^2}{ax-x^2}$: and therefore $=\frac{ay^2}{ax-x^2}$: this will be the parameter requested.

4. The axis AB, and the parameter AG, being given, we can affign any abscifs, as BP, its femi-ordinate PM, by drawing a line GB to the parameter AG, which is perpendicular to the axis AB; then, erecting a perpendicular PN, make PL=PH. Lastly, on AL defcribe a femicircle.

To find the femi-conjugate axis, ratio of the ordinates, &c. of an *ellipfis*. From B to L (*fig.* 23.) fet off half the parameter, then will CL$=\frac{1}{2}a-\frac{1}{2}b$. In the centre C erect a perpendicular CK, meeting the femicircle defcribed on AL: then will CK$=\sqrt{(\frac{1}{4}a^2-\frac{1}{4}b)}$; therefore making CF=CK, F will be the focus. The latter equation furnifhes us with this theorem.

If the axis AB be cut in the focus F, the rectangle under the fegments of the axis AF, FB will be fubquadruple of the rectangle under the parameter and the axis.

5. The parameter and axis AB given, the conjugate axis is eafily found, as being a mean proportional between the axis and parameter; conſequently, the parameter is a third proportional to the greater and leſſer axis. Add, that the ſquare of half the conjugate axis is equal to the rectangle, under the diſtances of the focus from the vertex, and its complement to the axis, or AF×FB (*fig.* 22.)

6. In an *ellipfis*, the ſquares of the ſemi-ordinates PM, p m, &c. are to each other, as the rectangles under the ſegments of the axis: hence, CD^2: PM^2:: CB^2: AP×PB; conſequently, DC^2: CB^2:: PM^2: AP× PB; that is, the ſquare of the leſs axis is to the ſquare of the greater, as the ſquare of the ſemi-ordinate to the rectangle under the ſegments of the axis.

7. The right line FO (*fig.* 24.) drawn from the focus F, to the extremity of the conjugate ſemi-axis, is equal to half the tranſverſe axis AC.

Hence, the conjugate axes being given, the foci are eaſily determined; for, biſecting the greater axis AB in C, from C erect a perpendicular CD equal to the conjugate ſemi-axis; then from D, with the interval CA, the foci F and f are determined.

8. *To defcribe an ellipfis.* The ſum of two right lines FM, and f M, drawn from each focus of an *ellipfis*, F and f, to the ſame point of the periphery M, being equal to the greater axis AB; the conjugate axes of an *ellipfis* being given, the *ellipfis* eaſily defcribed too, determining the foci F and f, as already directed, and having two nails thereon, and about them tying a thread FM f, equal to the length of the greater axis AB, and the diſtance of the foci; the thread being ſtretched, and a ſtyle or pin applied to it, and carried quite round (keeping the thread always the ſame length) deſcribes an *ellipfis*. See CONIC *Sections*.

9. The rectangle under the ſegments of the conjugate axis, is to the ſquare of its ſemi-ordinate, as the ſquare of the conjugate axis to the ſquare of the greater axis. Hence, the co-ordinates to the conjugate axis have the ſame relation as there is between the co-ordinates to the greater axis; conſequently, the parameter of the conjugate axis is a third proportional to the conjugate axis and the greater axis.

10. To determine the ſubtangent PT (*fig.* 25.) and ſubnormal PR in an *ellipfis*, as the firſt axis is to the parameter, ſo is the diſtance of the ſemi-ordinate from the centre to the SUBNORMAL.

11. The rectangle under the ſegments of the axis, is equal to the rectangle under the diſtance of the ſemi-ordinate from the centre and the SUBTANGENT.

12. As the diſtance of the ſemi-ordinate from the centre is to half the axis, ſo is the abſciſs to the portion of the ſubtangent intercepted between the VERTEX of the *ellipfis* and tangent.

13. The rectangle under the ſubtangent PT, and the abſciſs PC, is equal to the rectangle under the ſegments of the axis. Hence, the ſquare of the ſemi-axis AC is equal to the rectangle of CT, into PC.

14. The rectangle under the ſubtangent, and the diſtance of the ordinate from the centre, is equal to the difference of the ſquare of this diſtance, and the ſquare of the tranſverſe ſemiaxis.

15. In an *ellipfis*, the ſquare of the ſemi-ordinate to any diameter is to the ſquare of the conjugate ſemidiameter, as the rectangle under the ſegments of the diameter is to the ſquare of the diameter; conſequently, the relation of the ſemi-ordinates to the diameters is the ſame as to the axes; and the parameter of any diameter is a third proportional to that diameter and its conjugate. For other properties of the *ellipfis*, ſee CONIC *Sections*.

Infinite ellipſes are thoſe defined by the equation $a^{m-n}y^m+a^{m-n}x^m=a^m$, which ſome call *hyperbolas*, if m be greater than 1, or n greater than 1.

In reſpect of their curves, the *ellipſis* of the former kind is called the *hyperbolic ellipſis*.

It has been long known, that if a parallelogram, circumſcribed about a given *ellipſis*, have its ſides parallel to the conjugate diameters, then will its area be of an invariable or given magnitude, and equal to the rectangle contained by the axes of the figure; but this is only a caſe of a more general propoſition: for if, upon any diameter produced without the *ellipſis*, you take two points, on each ſide of the center, at equal diſtances from it, and four tangents be drawn from thoſe points to the *ellipſis*, theſe tangents will form a parallelogram, which is always of a given or invariable magnitude, when the *ellipſis* is given, if the ratio of thoſe diſtances to the diameter be given; and when the ratio of thoſe diſtances to the ſemi-diameter is that of the diagonal of a ſquare to the ſide (or of 2 to 1) the parallelogram will have its ſides parallel to the conjugate diameters. Phil. Tranſ. N° 468. p. 526.

Triangles, trapezia, or polygons, of any kind, may be determined, which, circumſcribed about a given *ellipſis*, are always of a given magnitude. For

If, upon any diameter produced without the *ellipſis*, any number of points be taken on the ſame, or on different ſides of the centre, at diſtances from it, that are each in ſome given ratio to that diameter; and from theſe points tangents be drawn to the *ellipſis*, in any one certain order; the polygon, formed by theſe tangents, is always of a given magnitude in a given *ellipſis*, and is equal to a polygon deſcribed by a ſimilar conſtruction about a circle, the diameter of which is a mean proportional betwixt the tranſverſe and conjugate axis of the *ellipſis*.

The polygons inſcribed in the *ellipſis*, by joining the points of contact (thus formed) and the ſectors, bounded by the ſemi-diameters, drawn to theſe points, are alſo of given or determined magnitude; and the parts of any tangent, intercepted betwixt theſe interſections of the other tangents, with it, or betwixt theſe interſections and the point of contact, are always in the ſame ratio to each other in the ſame figure. See Maclaurin's Fluxions, vol. i. p. 8. who obſerves that theſe is an analogous property of the other conic ſections.

ELLIPSIS, *quadrature of the*. See QUADRATURE.

ELLIPSIS, *rectification of the*. See RECTIFICATION.

ELLIPSIS, in *Grammar* and *Rhetoric*, is a verbal figure, or a figure of ſyntax, wherein ſomething is ſuppreſſed, or left out, in a diſcourſe, and ſuppoſed or underſtood; or, it is a defect or omiſſion of ſome part of a ſentence, which muſt be ſupplied in order to render the conſtruction complete. See on this ſubject the Port Royal Latin Grammar, vol. ii. p. 168, &c. See ZEUGMA.

This chiefly happens, when, being under the tranſport of a violent paſſion, a man is not at leiſure to ſpeak every thing out at length, the tongue being too ſlow to keep pace with the rapid motions of the mind; ſo that on theſe occaſions we only bring forth broken interrupted words and expreſſions, which repreſent the violence of a paſſion better than any conſiſtent diſcourſe.

M. Boſſu conſiders the *ellipſis* as a way of diſguiſing ſentences, by ſuppreſſing the word which ſhould make the particular application, and leaving the whole in a kind of ingenious ambiguity.

Thus

Thus, the Trojans, in Virgil, being rebuked by Turnus to the last extremity, and ready to be destroyed, fay Æneas coming to aſſiſt them; upon which the poet ſays, *ſpes addita ſuſtulit iras*. Which expreſſion ſignifies either, in particular, that the hope they conceive retrieves and augments their courage; or in general, that the hope of aſſiſtance at hand naturally raiſes courage, and gives people new ſtrength.

If the poet had added a word, and ſaid, *Ollis ſpes addita ſuſtulit iras*, the paſſage had been expreſsly reſtrained to the firſt ſenſe, and had ceaſed to be a ſentence, and commenced only the application of a ſentence: the impreſſion of that word makes it a ſentence in force.

This, that excellent critic looks on as one of the ſtrokes of the Latin tongue, wherein it had vaſtly the advantage of the modern tongues. Trait. du Poeme Epique, p. 466, &c.

ELLIPTIC, or ELLIPTICAL, ſomething that belongs to an *ellipſis*.

Kepler firſt maintained, that the orbits of the planets are not circular, but *elliptical*; which hypotheſis was afterwards eſtabliſhed by M. Boulliaud, Mr. Hamſfield, Sir Iſaac Newton, M. Caſſini, and others, of the later aſtronomers, have confirmed the ſame: ſo that this, which was once, by way of contempt, called *the elliptic hypotheſis*, is now the prevailing doctrine. Sir Iſaac Newton demonſtrates, that if any body revolve round another in an *ellipſis* only, its centripetal forces, or gravities, will be in a duplicate ratio; or, as the ſquares of its diſtances from the umbilicus, or focus.

Borlio, Hamſon, &c. endeavour to demonſtrate, that the beſt forms for arches, or vaults, is the *elliptical*. See ARCH. See alſo CATENARIA.

ELLIPTIC *ſpace*, is the area contained within the circumference or curve of the *ellipſis*. See ELLIPSIS.

It is demonſtrated, 1. That the *elliptic ſpace* is to a circle deſcribed on the tranſverſe axis, as the conjugate diameter is to the tranſverſe axis.

2. That the *elliptic ſpace* is a mean proportional between two circles deſcribed on the tranſverſe and conjugate axes.

ELLIPTIC *Conoid* is the ſame with the SPHEROID.

ELLIPTIC *ſpeculum*, or *Mirror*. See MIRROR.

ELLIPTIC *Hemiſpheres*. See STARS.

ELLIPTIC *Horſe-mill*. See WIND-MILL.

ELLIPTIC *Compaſſes*, an inſtrument made uſually in braſs, for the drawing of any ellipſis or oval, by one revolution of an index.

ELLIPTIC *Dial*, is an inſtrument uſually of braſs, with a joint to fall together, and the gnomon to fall flat, for the eaſe of the pocket.

By it are found the meridian, hour of the day, riſing and ſetting of the ſun, &c. See DIAL.

ELLIPTOIDES, an infinite elliptic, i. e. an ellipſis defined by the equation $a^m y^n + b^m x^n = a^m x^n - a^n$, wherein $m > 1$ or $n > 1$. See ELLIPSIS.

Of this there are ſeveral kinds or degrees: as the cubical *elliptoid*, wherein $a^3 y^2 = b^3 x^2 - x^3$. A biquadratic or ſurdeſolid *elliptoid*, or that of the third order, wherein $x^3 y^2 = b^3 x^2 - a^3$.

If any other ordinate be called v, and the correſpondent abſciſs z; there will be

$$a^{m+n} y^n : a^{m+n} y^n :: b^m x^1 - x^1 : b^m z^1 - z^1;$$

Conſequently,

$$a^{m+n} y^n : a^{m+n} y^n :: b^m x^1 - x^n : b^m z^1 - z^n;$$

That is, $y^n : v^n :: x^n - x^n : z^n - z^n$.

ELLISIA, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are theſe: the flower has a ſmall cylindrical empalement of one leaf, indented in five parts at the brim. It has one tubulous petal, whoſe brim is cut into five ſegments, which ſpread open: it has four ſtamina, two of which are longer than the other, and a roundiſh germen, which becomes a roundiſh berry, crowned by the empalement, enclofing eight nuts, which have two cells, with one ungular ſeed in each. We have but two ſpecies of this genus, which grows naturally in the Weſt Indies.

ELLOTIA, Feaſts, among the Greeks, a feſtival in memory of Europa, Agenor's daughter, who was called Eſſara by the people of Crete.

ELLYCHNIOTOS, in the medical writings of the Arabians, the name of a ſort of teſt uſed by the ſurgeons, and made of cotton or flax, rolled up into the form of the wick of a lamp or candle. See the next article.

ELLYCHNIUM, a name given by the ancients, to that ſort of matter, whatever it was, which ſerved them in common uſe for the wicks of their lamps, and had, beſide this, its uſe in ſurgery. Galen expreſly directs the uſe of the aſbeſtine *ellychnium*, inſtead of that of Tarſus, inſtead of ſponge, in chirurgical caſes. But we are in from being aſcertained, at preſent, of what this *ellychnium* of Tarſus was. The commentators have gueſſed differently as to the meaning of the word; and ſome ſuppoſe it to ſignify a ſort of ſponge and lint; which, when properly wrought up, might be made to ſerve for the wicks of lamps, being very inflammable, as we well know many of the fungules to be, particularly that ſort which the people of ſome countries call ſpunck, and uſe inſtead of tinder, to catch fire from the ſparks of flint and ſteel; and when in its natural lax ſtate, might, by its open ſponge texture, be very well ſuited to imbibe any medicinal fluid, and retain it a long time, while applied to any diſeaſed part. Others have gueſſed it to be the xylon, or cotton of the ancients; but from Galen's propoſing it to be uſed inſtead of ſponge it ſeems much more probable to have been what Cornarius ſuppoſes. Galen, lib. xiii. and xiv. Cornar. Comment. in 3 Exod. cap.

ELM, *Ulmus*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: the flower has a rough permanent empalement of one leaf, cut into five points, and coloured within; it has no petals, but five awl-ſhaped ſtamina, twice the length of the empalement, terminated by ſhort, erect ſummits, having four furrows, and an orbicular erect germen, ſupporting two ſtyles which are reflexed, and [illegible]

The germen afterward ripens [illegible] bordered capſule, including [illegible] ſeed. Linnæus enumerates [illegible]

All the ſpecies of the *elm* may [illegible] layers, or by ſuckers taken [illegible] theſe are often taken up [illegible] therefore very ſubject to [illegible] is much the beſt, and is very [illegible] ſmall ſpace of ground: wood [illegible] reſinent for a number of [illegible] ſoil for a nurſery of this kind, in a moderately light and dry hazel loam, and the beſt ſeaſon for laying the tranſlues is autumn. When they have taken root, they ſhould be removed from the old plant, and ſet in rows in nurſery beds, where, after four or five years, they will be ſtrong enough to be tranſplanted into the places where they are to remain. In planting them, great care is to be taken not to bury their roots too deep, which, when the ſoil is moiſt and ſtiff, often deſtroys them. The common *elm* ſeldom produces ſeed in great perfection, but the witch *elm* produces great quantities of good ones, from which ſome people raiſe nurſeries of the trees. Miller. See FECUNDITY.

Elm-trees are proper for hedges near the borders of fields, or for defending houſes or gardens from the violence of winds. *Elm* wood is uſed in various kinds of waterworks; and the fineneſs of the grain makes it fit for carving. The bark has been ſometimes commended both for its purgative and aſtringent virtue; but neither appear to have any foundation.

ELMOROSIA, a name given by the Moors to a diſh they are very fond of. It is made of pieces of beef, or of camel's fleſh, ſtewed with butter, honey and water; ſome add roſh of wine to it, and others garlic; but there are always added onions, ſaffron, and ſalt. Phil. Tranſ. N° 253.

ELOANA, a name given by ſome writers to *anſpeguation*, or aſpiration.

ELOCUTION, is defined by Tully, the chooſing and adapting of words, and ſentences, to the things, or ſentiments, to be expreſſed. To the *elocution* then properly belongs the *delectus verborum*, or *choice of words*. That which treats of the ſeveral properties and ornaments of language in common, is called *general elocution*, conſiſting of ELEGANCE, COMPOSITION, and DIGNITY: and particular *elocution* conſiders them as they are made uſe of to form different ſorts of ſtyle.

ELOCUTION is ſometimes alſo more reſtrictedly to denote the juſt and graceful management of the voice, countenance, and geſture, in ſpeaking: and in this ſenſe it is the ſame with that which, in common language, is called a good delivery. As to that part which reſpects the management of a voice, it includes articulation, pronunciation, accent, emphaſis, pauſes, tones, and quick or key: and the other requiſite of good delivery is GESTURE. See ARTICULATION, &c. Sheridan's Lectures, &c. Lect. 2, &c. &c.

The beauties of *elocution* conſiſt chiefly in the uſe of figures, and figurative dictions or expreſſions, in the periods, and the ſtyle. See FIGURE, PERIOD, and STYLE. Watts's Or. p. 307.

ELODES, in *Botany*, an epithet given to a very ſoft and woolly ſort of St. John's wort, or *hypericum*.

ELODES is alſo uſed, among the ancient writers in *Medicine*, for a ſpecies of fever, attended with profuſe ſweats.

ELOGIUM, ELOGE, a praiſe, or panegyric, beſtowed on any perſon, or thing, in conſideration of its merit.

The word is Latin, but formed of the Greek εὐλογία, *commendation*;

commendation; which is compounded of *eu*, well; and *logu*, *to say*, or *speak*.

The secretary of the Royal Academy of Sciences at Paris composes the *eloges* of such members as die; and delivers them at the next public meeting of the company. Funeral orations are *eloges* of eminent persons deceased.

Extravagant and improbable *eloges* are of the greatest disservice to their own design; and do, in effect, diminish the person whom they pretend to magnify. Any worthy man may pass through the world unquestioned and safe, with a moderate recommendation; but when he is set off and bedawbed with rhetoric, and embroidered so thick, that you cannot discern the ground, it awakens naturally (and not altogether unjustly) interest, curiosity and envy; for all men pretend a share in reputation, and love not to see it engrossed, or monopolized; and are therefore apt to enquire (as of great estates suddenly got) whether the person, so commended, came honestly by it, and of what credit the person is that tells the story.

ELOHA, in *Scripture*, the singular of ELOHI, one of the names of God.

ELOHI, ELOI, or ELOHIM, in *Scripture*, one of the names of God. But it is to be observed, that angels, princes, great men, judges, and even false gods, are sometimes called by this name. The sequel of the discourse, is what [illegible] us in judging rightly concerning the true meaning of it in [illegible]. It is the same as *Eloha*; one is the singular, the other the plural. Nevertheless *Elohim* is often [illegible] singular number, particularly when the [illegible] of; but when false gods are spoken [illegible] rather in the plural. Calmet, Diction [illegible]

[illegible] ...ous, signifies to remove, or send a great [illegible] in fact, if such as be within age be [illegible], so that they cannot come to sue personally, their next friends shall be admitted to sue for them. Stat. 13 Edw. I. cap 15.

ELOME, a name given by some authors to ORPIMENT.

ELONGATA, in *Law*, is a return of the sheriff, that cattle are not to be found, or removed, so that he cannot make deliverance in replevin.

ELONGATION, in *Astronomy*, the digression, or recess of a planet from the sun, with respect to an eye placed on our earth; or it is the angle formed by two lines drawn from the earth to the sun, and from the earth to the planet, or the arc measuring this angle.

The greatest distance of the planet, &c. from the sun, is called the *greatest elongation*; which varies on two accounts, viz. in that both the earth, and the planet, revolve, not in circles, but in ellipses; and the variation is greatest in the orbit of Mercury, which is the most elliptic. In a circular orbit, having the sun for its centre, the greatest *elongation* would happen, when the right line, joining the earth and planet, touched the orbit of the planet; and this might easily be found, because the tangent to the orbit, and the distances of the earth and of the planet from the sun, form a right-angled triangle, in which, having two sides, viz. the distances, the vertical angle, or angle of *elongation*, may be easily found. But in an elliptic orbit it may happen, that the *elongation* from the sun may grow still greater, even after it has left the place where the line joining the earth and planet touches its orbit. For after that, the true distance of the planet from the sun may increase, whilst the distance of the sun and planet from the earth do not increase, but they may rather decrease; and therefore in two triangles the greater base will subtend the greater angle. If the greatest *elongation* be found by observation, the distance of the planet from the sun, supposed to move in a circular orbit, may be obtained, in respect of the earth's distance from the sun. Keill's Astron. p. 157.

The *elongation* is chiefly considered in Venus and Mercury. The *greatest elongation* of Venus is 48 degrees, and that of Mercury 28 degrees; that is, the former never recedes from the sun, or is seen distant from him, above 48°, nor the latter above 28°. Whence it is, that Mercury is so rarely visible; as being usually lost in the light of the sun. See MERCURY, and VENUS.

The *elongation* of the superior planets from the sun may amount to 180°; or they may be in opposition to the sun, as viewed from the earth.

ELONGATION is also used, by some authors, for the difference in motion, between the swiftest and the slowest of two planets; or the quantity of space, whereby the one has overgone the other; called also *superation*.

The swiftest motion of the moon, with regard to the sun, is called the *elongation* of the moon from the sun. We also say, diurnal *elongation*, horary *elongation*, &c.

ELONGATION, *angle of*, or *angle at the earth*, is the difference between the sun's true place, and the geocentric place of a planet. Such is the angle ETR (*Tab. Astron. fig.* 25.) between the place of the sun E, and that of the planet R.

ELONGATION, in *Surgery*, is an imperfect luxation: when the ligament of any joint is so extended, or relaxed, as to lengthen the limb, but yet not to let the bone go quite out of its place. See LUXATION.

ELOPEMENT, in *Law*, is when a married woman, of her own accord, departs from her husband, and dwells with an adulterer; for which, without voluntary reconcilement to the husband, she shall lose her dowry; nor shall the husband, in such case, be compelled to allow her any alimony.

Sponte virum mulier fugiens, & adultera factâ
Dotis jus perdit, nisi fœdus fronte recalla.

The word is formed from the Belgic, *Er*, *matrimony*, and *loopen*, *to run away*.

However, mere advertising a wife in the Gazette, or other public papers, is not a legal notice to persons in general not to trust her; though a personal notice given by the husband to particular persons is said to be good. An action lies, and large damages are usually given, against a person for carrying away, and detaining another man's wife.

ELOPIVINUM, a name given by some of the old chemists to vitriol.

ELOPS, *Elaps*, in *Zoology*, the name of a serpent, otherwise called ELAPS.

ELOPS was also the name of a fish much esteemed among the Greeks, and thought to be the same with the ACCIPENSER. Hofm. Lex. in voc.

ELOQUENCE, the art of speaking, or writing well; so as to move and persuade. See RHETORIC, and ORATORY.

If *eloquence* and rhetoric be distinguished, the latter may be considered as proposing and explaining the theory, and the former as the practice of the art: but they are generally used indiscriminately for each other.

Demosthenes and Cicero are the two patterns of ancient *eloquence*; the one among the Greeks, the other among the Romans. Their manner, however, was exceedingly different; the first being close, strong, nervous, concise, and severe, so that a word could not be spared; the latter copious, florid, and rich, so that a word could not be added.

It was objected to Cicero, that his *eloquence* was Asiatic, that is, redundant, or flushed with superfluous words and thoughts.

Pericles was called a *torrent of eloquence*, a *thunderbolt of eloquence*. Pedants do not distinguish *eloquence* from the heaping up of figures, the use of big words, and the rotundity of periods.

True *eloquence* depends principally on the vivacity of the imagination. In strictness, it is not that which gives grace and ornament, but life and motion, to discourse. The authors of the Art of Thinking remark, that the rules of *eloquence* are observed in the conversation of people naturally *eloquent*, though they never think of them, while they practise them. They practise those rules, because they are *eloquent*; not in order to be *eloquent*.

The *eloquence* of the chair, and pulpit, is much more difficult than that of the bar. Sir George Mackenzy has a treatise of the *eloquence* of the bar. Idea *Eloquentiæ forensis*, &c.

ELOSSITES, in *Natural History*, the name of a stone, mentioned with great respect by the writers of the middle ages; they have left us, however, to shoot a description of it, that it is impossible to determine what it was; they only say, that it was no very beautiful stone, but that, if worn in the pocket, it had a wonderful virtue in curing pains, and all other diseases in the head.

ELIES, a name given, by some of the chemical writers, to the scoria of silver.

ELPISTICI, *Ελπιστικοι*, among the Greeks, a sect of philosophers who made hope the ruling passion of mankind.

ELTHYMUM, in the *Materia Medica of the Ancients*, a name given to the epithymum, or dodder growing upon thyme.

ELUDING, the act of evading, or rendering a thing vain, and of no effect; a dextrous getting clear, or escaping out of an affair, difficulty, embarrassment, or the like.

We say, to *elude* a proposition, &c. The design of chicanery is, to *elude* the force of the laws: this doctor has not resolved the difficulty, but *eluded* it. Alexander, says the historian, in cutting the Gordian knot, either *eluded* the oracle, or fulfilled it: *Ille nequaquam luctatus cum lentissimis nodis, Nihil, inquit, interest, quomodo solvantur; gladioque ruptis omnibus hæsit, an caute sortem, vel eludit, vel explevit.* Q. Curt. 13.

ELVÆ. See ELFS.

ELVELA, in *Botany*, a name given by Linnæus to a genus of funguses, called by Micheli *fungi capites*, and *fungoides*.

These differ from all other kinds of fungoſes, in that they are ſmooth both on the upper and under ſide, having no marks of lamellæ, pores, or fibres, in any part.

ELVERS, an Engliſh name for a ſmall ſort of eels, caught in ſome parts of the kingdom, particularly about Glouceſter and Tewkeſbury. Theſe are, in reality, young congers, or ſea eels. They get up into rivers while very ſmall, and as they precede the ſhads, it is conjectured that they ſupply them with food. They are taken in prodigious numbers in the rivers, in dark nights, by a kind of ſieve made of hair-cloth, fixed to a long pole, and are eſteemed a very delicate food. Willughby.

ELUL, one of the Hebrew months, anſwering partly to our Auguſt and September. There are but nine and twenty days in it. It is the twelfth month of the civil year, and the ſixth of the eccleſiaſtical. Upon the ſeventh or ninth day of this month the Jews faſt, in memory of what happened after the return of thoſe who went to view the promiſed land, Numbers, xiii. xiv.

Upon the twenty-ſecond of this month the feſtival of the *xylophori* was obſerved, when wood was carried to the temple. Selden ſays, that it was celebrated on the eighteenth day of the month *Ab*. On the twenty-ſixth of the ſame month, the dedication of the walls of Jeruſalem by Nehemiah was commemorated. Joſeph. lib. ii. cap. 17. p. 811. Nehem. xii. 27, &c. Calmet, Dictionn. Bibl.

ELUTRIATION, in *Metallurgy*, is the ſeparating of the lighter matters from the mixt ores of metals, by means of great quantities of fair water. Solid bodies, not diſſoluble in water, are by this operation ſeparated from each other by water very well ſtirred, ſo that the lighter and finer parts are carried away with the water, and the heavier and more ſolid remain at the bottom of the veſſels.

Some of the ſtones, earths, and other bodies, naturally mixed with the ores of metals, are much lighter than the metalline parts of thoſe ores, and are therefore very eaſily thus ſeparated from the reſt by this operation, either by barely pounding and waſhing, or by firſt calcining, and then eatinguiſhing them in water, and afterwards waſhing them.

The kinds of ores, proper to be made the ſubjects of this operation, are known from the great ſpecific gravity of the ore, which ſhews us that the metallic maſſes, adhering to their matrix, are firm and ſolid, and combined in large molecules, not ſmall, and ſcattered and diſperſed ſparingly through it; they are known alſo by the comparative lightneſs and brittleneſs of their ſtony matrix: whether this laſt property be naturally inherent in the ſtony matter, or whether it be eaſily brought on by fire in calcination, for in ſuch caſe it renders the commination of the compound maſs eaſy. In this caſe, however, it is proper, that the ore itſelf be of a nature ſufficiently fixed afterwards in the fire, and doth not fly away in the roaſting.

When ſtones, containing ore in them, are light and brittle, but hold a great quantity of ſulphur, and are interſperſed only with very minute maſſes of the metalline particles, or when theſe are incloſed in a very ponderous and hard matrix, not eaſily affected by fire, this method of ſeparation has no place. Cramer, Art of Aſſ. p. 195.

ELYCHRISUM, in *Botany*. See CUDWEED, and GOLDY *Locks*.

ELYSIUM, *Elyſium*, in the *Ancient Theology*, or rather *Mythology*, a place in the inferi, i. e. in the lower world, or, as we ſometimes render it in bell; furniſhed with fields, meads, agreeable woods, groves, ſhades, rivers, &c. whither the ſouls of good people were ſuppoſed to go after this life.

Orpheus, Hercules, and Æneas, are ſuppoſed to have deſcended into *elyſium*, in their life-time, and to have returned again. Virgil, lib. vi. ver. 638, &c. Tibullus, lib. i. eleg. 3. give us fine deſcriptions of the *elyſian fields*.

Virgil oppoſes *elyſium* to tartara; which was the place where the wicked underwent their puniſhment.

Hoc locus eſt, partes ubi ſe via findit in ambas:
Dextera, quæ Ditis magni ſub mania tendit:
Hac iter elyſium nobis: at læva malorum
Exercet pœnas, & ad impia tartara mittit.

He aſſigns *elyſium* to thoſe who died for their country, to thoſe of pure lives, to truly inſpired poets, to the inventors of arts, and to all who have done good to mankind.

Some authors take the fable of *elyſium* to have been borrowed from the Phœnicians; as imagining the name *elyſium* formed from the Phœnician עלץ. *alez*, or עלץ *alatz*, or עלס, *alas*, *to rejoice*, or *to be in joy*; the letter *z* being only changed into *s*, as we find done in many other names; as in *Enakim*, for *Anakim*, &c. On which footing, *elyſian* fields ſhould ſignify the ſame thing as a place of pleaſure: or,

——*Lætas ſedes, & amœna virecta*
Fortunatorum nemorum, ſedeſque beatas. Virg.

Others derive the word from the Greek λυω, *ſolvo*, *I deliver*, *I let looſe*, or *diſengage*, becauſe here men's ſouls are freed, or diſincumbered, from the fetters of the body. Beroaldus, and Hornius, Hiſt. Philoſoph. lib. iii. cap. 2. take the place to have derived its name from Elisa, one of the firſt perſons who came into Greece after the deluge, and the author and father of the Æolians. Ol. Rudbeck contends, that it was in Sweden the *elyſian* fields were placed.

ELYTROIDES, Βοατροειδης, in *Anatomy*, one of the proper coats, or tunics of the TESTICLES.

The word is formed of the Greek ελυτρον, *vagina*, *a ſheath*, and ειδος, *form*.

The *elytroides* is the ſecond proper coat of the teſtes: it reſembles a ſheath, or vagina; whence ſome have alſo called it *vaginalis*.

It is formed of a dilatation of the production of the peritonæum; its inner ſurface is ſmooth and equable; and the outer rough and unequal; which makes it adhere the more ſtrongly to the firſt of the proper coats, called *cyſtoides*.

ELYTRON, properly a covering of any ſort, and for any ſubſtance. Hippocrates has appropriated the word to ſignify the membranes which involve the ſpinal marrow.

EL ZIMAR, a name given, by ſome of the chemical writers, to the flowers of braſs.

EMANATION, the act of flowing, or proceeding, from ſome ſource, or origin. Such is the *emanation* of light from the ſun; or that of effluvia from odours, &c. bodies; of wiſdom from God, &c.

The word is formed of the Latin *e*, *ex*, *of*, and *manare*, *to flow*, or *ſtream*.

EMANATION is alſo uſed for the thing that proceeds, as well as the act of proceeding. The power given a judge is an *emanation* from the regal power; the reaſonable ſoul is an *emanation* from the divinity.

EMANATION is alſo uſed among the ſchoolmen, for the production of a leſſer thing, in order to the production of a greater, by virtue of ſome natural connexion, or dependence, between them.

For, as when ſeveral moveables are joined together, the ſame power that moves the firſt, moves all the reſt (as in pulling up the trunk of a tree, you pull up the roots, branches, &c. or in drawing one link of a chain, you bring forward all the reſt); the ſame is to be underſtood, in all conjunct natural effects; viz. that the ſame power whereby the firſt is produced, does alſo produce all the reſt, naturally connected with it; becauſe, by means of the connexion, the action of the agent, is conveyed from one to the other; ſo that the firſt determines the agent to the production of all the reſt.

And hence that is called an *emanative cauſe* (in contradiſtinction to an efficient cauſe) which produces an effect by its mere preſence, without the intervention of any action; as a roſe doth a ſmell, &c. Others, and with good reaſon, deny that there is any ſuch thing as an *emanative cauſe*, to produce an effect without any action. See CAUSE.

EMANCIPATION, in the Roman *Law*, was the act of ſetting a ſon free from the power and ſubjection of his father.

The word is formed from the Latin *ex*, *of*, and *mancipium*, *a ſlave*.

Emancipation differs from *manumiſſion*; as the latter was the act of a maſter in favour of a ſlave; the former that of a father in favour of his ſon.

The effect of *emancipation* was, that the goods, and moveable effects, which the ſon ſhould thenceforth acquire, ſhould be his ſole property, and not the property of his father; as they were before *emancipation*. Beſides, *emancipation* put the ſon in a capacity of managing his own affairs, and of marrying without his father's conſent, though a minor, or pupil, and under twenty-five years of age.

There were two kinds of *emancipation*; the one *tacit*, which was, by the ſon's being promoted to ſome dignity, or by his coming of age, or by marriages in all which caſes, the ſon became his own maſter of courſe.

The other *expreſs*, where the father declared before the judge that he *emancipated* his ſon. This was not performed without ſome formality: the father was firſt to ſell his ſon, imaginarily, to another man, whom the lawers call *pater fiduciarius*, *father in truſt*; of whom being bought back again by the natural father, he manumitted, or ſet him free, by a declaration before the judge.

This

This imaginary fale was called *mancipatio*; and the mamomiſſion, conſequent thereon, *emancipatio*.

Emancipation ſtill obtains in France, chiefly, with regard to minors, or pupils, who are hereby ſet at liberty to manage their effects, without the advice, or direction, of their fathers or tutors. It muſt be obſerved, however, that *emancipation* only extends to the ſelling of moveables, and letting of leaſes, &c. of immoveables; not to the ſelling or mortgaging of immoveables; which are only done with the conſent of a curator, ordinarily a perſon appointed, when *emancipated*.

Formerly *emancipation* was performed in the ordinary courts of juſtice, when deſired by the child; but if he were a minor, the king's letter was alſo required. Though there were other ways of *emancipation*, as by marriage; arriving at the age of twenty years; and in ſome provinces, by the death of the mother, becauſe the children were there under the power of the father and mother conjointly; ſo that the death of either of them *emancipated* the child.

Emancipation by marriage, in France, gives a power of marrying again, without the father's conſent, though under age; but among the Romans, Cujas tells us, a widow, under twenty-five years of age, though *emancipated* by her former marriage, returned into the power of the father, and might not marry a ſecond time, without his conſent.

Du-Cange obſerves, that the word *emancipation* was alſo uſed in the monaſteries, in ſpeaking of monks, promoted to any dignity, or removed from under the power of their ſuperiors; as alſo in ſpeaking of monaſteries, chapels, &c. themſelves, when exempted, by the pope, from the juriſdiction of the ordinary.

EMARGINATED *leaf*, among *Botaniſts*. See LEAF.

EMASCULATION, the act of taking from a male thoſe parts which are characteriſtic of his ſex. See CASTRATION.

EMAUX *de l'Eſcu*, in *Heraldry*, the metals and colours of a ſhield, or eſcutcheon.

EMBALMING, the opening of a dead body, taking out the inteſtines, and filling their place with odoriferous and deſiccative drugs and ſpices, to prevent its putrefying.

The word is formed from *balm*, which was a principal ingredient in the *embalmings* of the ancient Egyptians.

Dr. Grew, in his Muſeum Regalis Societatis, is of opinion, that the Egyptians boiled their bodies in a large cauldron, with a certain kind of liquid balſam. His reaſon is, that in the mummies preſerved in the collection of the Royal Society, the balm has penetrated not only the fleſhy and ſoft parts, but even the very bones; ſo that they are all as black as if they had been burnt.

The Peruvians had an effectual method of preſerving the bodies of their incas, or kings, *embalmed*.

The way of *embalming* dead bodies among the Egyptians was as follows: when a man died, his body was carried to the artificers, whoſe trade it was to make coffins; they took the meaſure of the body, and made a coffin for it, proportioned to its ſtature, the dead perſon's quality, and the price that people were willing to give. The upper part of the coffin repreſented the perſon who was to be ſhut up in it, whether man or woman. If it was a man of condition, this was diſtinguiſhed by the figure which was repreſented on the cover of the coffin; there were generally added paintings and embelliſhments, ſuitable to the quality of the perſon. Vide Callian. Collat. 15. cap. 3. & Cicero, Tuſc. Quæſt. lib. i. Herodot. lib. ii. cap. 86. Diodor. lib. ii. cap. 5.

When the body was brought home again, they agreed with the *embalmers* at what rate particularly they would have it *embalmed*, for the prices were different; the higheſt was a talent, that of twenty minæ was a moderate one, and the loweſt price was a very ſmall ſum. The Egyptian talent is ſuppoſed to be worth three hundred pounds ſterling. They immediately ſent for a deſigner, who marked the body, as it lay extended, at the place where it ſhould be opened, on the left ſide, and the length of the inciſion. A diſſector, with a very ſharp Ethiopian ſtone, made the inciſion, and hurried away as faſt as he could, becauſe the relations of the perſon deceaſed, who were preſent, took up ſtones, and purſued him as a wicked wretch, with an intention to ſtone him.

This operation being finiſhed, the *embalmers*, who were looked upon as ſacred perſons, entered to perform their office. They drew all the brains of the dead perſon through his noſtrils, with a hooked piece of iron, provided particularly for this purpoſe, and filled the ſkull with aſtringent drugs; they likewiſe drew all the bowels, except the heart and kidneys, through the aperture which they had made in the ſide. The inteſtines were waſhed in wine from the palm-tree, and in other ſtrong and binding drugs. The whole body was anointed with oil of cedar, with myrrh, cinnamon, and other ſpices, for about thirty days, ſo that it was preſerved entire, not only without putrefaction, but had a good ſcent with it. Αρωσιν δε τα σωματα εβδομηκοντα ταριχευσαντες αυται. And the Perſians, as the ſame author Sextus Empiricus obſerves, were uſed ωτου ταριχευσιν. Sext. Empir. Pyrrhon. Hypoth. lib. ii. cap. 24.

Bodies thus preſerved are called *mummies*, from the Arabic word *mum*, which ſignifies *wax*, this being an ingredient in the preparation.

After this the body was put into ſalt for about forty days; whereſore when Moſes ſays, that forty days were employed in *embalming* Jacob, we are to underſtand him as meaning the forty days of his continuing in the ſalt of nitre, without including the thirty days paſt in performing the other ceremonies above mentioned, ſo that, in the whole, they mourned ſeventy days in Egypt, as Moſes likewiſe obſerves.

Afterwards the body was taken out of the ſalt, waſhed, wrapt up in linen ſwadling-bands, dipped in myrrh, and rubbed with a certain gum, which the Egyptians uſed inſtead of glue. Then the body was reſtored to the relations, who put it in a coffin, and kept it in their houſes, or in tombs made particularly for this purpoſe. There are ſome found, at this day, in Egypt, in chambers, or ſubterraneous vaults, which fully juſtify the truth of what is here ſaid.

They who were not rich enough to bear this expence, contented themſelves with inſuſing, by a ſyringe, through the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapt up the body in ſalt of nitre. This oil preyed upon the inteſtines, ſo that when they took it out, the inteſtines came along with it diſſolved, and not in the leaſt putrefied. The body being enclofed in nitre, grew dry, and nothing remained, beſides the ſkin glued upon the bones. They who were too poor to be at any conſiderable expence, did no more than cleanſe the inſide, by ſyringing a liquor into it; this done, they put the body, without farther ceremony, into nitre for ſeventy days, in order to dry it. Calmet, Diction. Bibl. Pococke's Deſcription of the Eaſt, vol. i. p. 230, &c.

The preſent method of *embalming* in Egypt differs very much from the ancient. Maillet informs us, that it is now the cuſtom to waſh the body ſeveral times in roſe-water; then to perfume it with incenſe, aloes, and other odours, in great abundance; the body is afterwards wrapped up in a winding ſheet, made partly of ſilk, and partly of cotton, moiſtened probably with ſome liquid perfume; this is again covered with another cloth of unmixed cotton, to which is added one of the richeſt ſuits of cloaths of the deceaſed. Letter X. p. 88.

It is no wonder that we find human bodies preſerved without corrupting for many ages, by means of ſpices, and other ingredients, proper to reſiſt putrefaction, applied with the niceſt care; but it is ſtrange that there ſhould be a ſort of *embalming* performed by nature, in ſome places, where bodies are preſerved merely by the virtues of the ſoil in which they lie; yet this is evidently the caſe in ſome inſtances. We have, in the Philoſophical Tranſactions, an account of a man and a woman who were loſt in the great ſnows on the moors of Hope, near the woodlands in Derbyſhire, on the fourteenth of January, 1674. Theſe perſons were not found till the third of the May following, at which time they ſmelt ſo ſtrong, that the coroner prudently ordered them to be buried on the ſpot. Theſe bodies lay buried in the peat-moſs twenty-eight years before they were looked at again, when ſome people of the country, who had heard of the ſtrange virtues of the ſoil thereabouts in preſerving dead bodies, opened the ground, and found them no way altered, the colour of the ſkin being fair and natural, and the fleſh as ſoft as that of perſons newly dead. Phil. Tranſ. N° 434. p. 415.

After this the place was remarked where they lay, and they were ſhewn for a ſight for twenty years, though they were much changed by having been ſo often uncovered in that time.

EMBARCADERO, in *Commerce*, a Spaniſh term, much uſed along the coaſts of America, particularly thoſe on the ſide of the South Sea.

It ſignifies a place which ſerves ſome other conſiderable city farther within land, for a port, or place of ſhipping, i. e. of *embarking*, and *diſembarking* commodities.

Thus Calao is the *embarcadero* of Lima, the capital of Peru; and Arica the *embarcadero* of Potoſi. There are ſome *embarcaderos* forty, fifty, and even ſixty leagues off the city which they ſerve in that capacity.

EMBARGO, a reſtraint or prohibition, laid by a ſovereign on merchant veſſels, to prevent their going out of port; ſometimes to prevent their coming in; and ſometimes both, for a limited time.

Embargoes are uſual in time of war; in apprehenſions of inva-

invasions, &c. One great occasion of *embargoes* is, that the government may make use of the merchant-vessels, with their equipage, &c. in armaments, expeditions, transporting of soldiers, &c. another is, to stop the communication of intelligence at such critical seasons. *Embargoes* are of very mischievous consequence to commerce.

EMBARRAS, EMBARRASMENT, a French term, though now naturalized, denoting a difficulty, or obstacle, which perplexes or confounds a perſon, &c.

EMBASIS, in the writings of the *Ancient Phyſicians*, the name of a large veſſel, in which they prepared their medicated baths, and which was capable of holding the perſon to be bathed at his full length.

EMBASSADOR, or AMBASSADOR, a public miniſter, ſent from one ſovereign prince, as a repreſentative of his perſon, to another.

The word is derived from the corrupt Latin *ambaſciator*, formed of *ambactus*, an old word borrowed from the Gauliſh, ſignifying *ſervant, client, domeſtic*, or *officer*. Such is the origin given by Borel, Menage, and Chiflet, after Salmaſius and Spelman.

In Latin we uſually call this kind of miniſter *legatus*, or *orator*; though it is certain the word *embaſſador*, with us, has a much more extenſive ſignification than that of *legatus* among the Romans; and, excepting that they are both under the protection of the law of nations, there is ſcarce any thing in common between them.

Embaſſadors are either *ordinary* or *extraordinary*.

EMBASSADOR *in ordinary* is he who reſides ſtatedly in the court of another prince, to maintain a mutual good underſtanding, look to the intereſts of their maſters, and tranſact ſuch affairs as may occur.

Embaſſadors in ordinary are but of modern invention; it is not above two hundred years ago ſince they were firſt heard of; till then, all *embaſſadors were extraordinary*, and retired as ſoon as they had diſpatched the affair they were ſent upon.

EMBASSADOR *extraordinary* is a perſon who is ſent to a prince's court on ſome particular and emergent occaſion; as to conclude a peace, marriage, or to make a compliment, &c.

Indeed there is no eſſential difference between *ordinary* and *extraordinary embaſſadors*; they equally enjoy all the privileges and prerogatives which the law of nations decrees.

At Athens the *embaſſadors* from foreign princes and ſtates always mounted the tribunal, or pulpit, of the public orators, and there opened their commiſſion, and acquainted the people with their buſineſs. At Rome they were introduced to the ſenate, and delivered their commiſſion to them. Among us, they make their addreſs immediately and ſolely to the king.

Athens and Sparta, ſays M. Tourreil, when in all their glory, were never ſo much delighted as to ſee and hear a number of *embaſſadors*, in their aſſemblies, ſuing for their protection or alliance. It ſeemed to them the nobleſt homage that could be paid them; and that ſtate, which received the moſt embaſſies, was judged to have the advantage over the other.

The name of *embaſſador*, Cicero obſerves, is ſacred and inviolable: *non modo inter ſuiorum jura, ſed etiam inter hoſtium tela inviolatus verſatur*. In Verr. Oat. vi.

The *embaſſadors* of kings ſhould never attend at any public aſſemblies, marriages, interments, or other ſolemnities, unleſs their maſters have ſome intereſt therein: nor muſt they even go into mourning, or the like, on any occaſions of their own, becauſe they repreſent the perſons of their princes; and for this reaſon, they owe no ſubjection to any laws but thoſe of their own country, and their actions are not ſubject to the controul of the private law of that ſtate, in which they are appointed to reſide. It has been held, both by our common lawyers and civilians, that an *embaſſador* is privileged by the law of nature and nations; and yet, if he commits any offence againſt the law of reaſon and nature, he ſhall loſe his privilege; and therefore, if an *embaſſador* conſpires the death of the king in whoſe land he is, that he may be condemned and executed for treaſon: but if he commits any other ſpecies of treaſon, he muſt be ſent to his own kingdom. However, though theſe principles might fortunately obtain, the general practice of this country, as well as of the reſt of Europe, ſeems now to purſue the ſentiments of the learned Grotius, De Jur. Bell. & Pac. p. 18. *A*. that the ſecurity of *embaſſadors* is of greater importance than the puniſhment of a particular crime. And, therefore, few, if any, examples have occurred within a century paſt, where an *embaſſador* has been puniſhed for any offence, however atrocious in its nature. With reſpect to civil ſuits, neither an *embaſſador*, nor any of his train or *comites*, can be proſecuted for any debt, or contract, in the courts of that kingdom where he is ſent to reſide. By 7 Anne, cap. 12. an act paſſed in 1708, in conſequence of the arreſt of an *embaſſador* from Peter the Great, czar of Muſcovy, for a debt of 50*l.* all proceſs, whereby the perſon of any *embaſſador*, or of his domeſtic, or domeſtic ſervant, may be atteſted, or his goods diſtrained or ſeized, ſhall be utterly null and void, and the proſecutors be puniſhed at the diſcretion of the lord-chancellor, and the two chief juſtices, or any two of them. However, no bankrupt under, retained in the ſervice of an *embaſſador*, ſhall be privileged by this act; nor any ſervant, whoſe name is not regiſtered with the ſecretary of ſtate, and tranſmitted to the ſheriffs of London and Middleſex. Theſe privileges are allowed in the courts of law. Blackſtone's Commentaries, vol. i. p. 253, &c.

EMBASSY, or AMBASSY, *Legatio*, a miſſion from one ſovereign prince, or ſtate to another, of ſome able experienced perſon, to negociate ſome affair, in quality of *embaſſador*.

Fa. Daniel obſerves, that under the ancient French kings, their *embaſſies* conſiſted of a body, or number of perſons, joined together in commiſſion, and who compoſed a kind of council; ſomething like which is ſtill retained at treaties of peace. Thus the French *embaſſy* at Nimeguen, for the peace, conſiſted of three [illegible] that of Utrecht, of two, &c.

We likewiſe read of *embaſſies* [illegible] chale de Guebriant, Wicquefort, [illegible] and perhaps the only woman [illegible] rope in quality of *embaſſatrix*. [illegible] d'Henry IV. tells us, that the [illegible] of his court on an *embaſſy* to the [illegible] troubles of the empire.

EMBATTLED, a term in *Heraldry*, [illegible] any ordinary is notched after the [illegible] II. *Heraldry, fig.* 59. repreſenting the battlements of a wall, or caſtle. See BATTLEMENT.

None were ſuffered, in ancient times, to embattle their houſes, but thoſe who had great dignities, as the barons, and the like. Camden proves this in his account of Tunſtall's ſeat in England, in which he expreſſes it as a ſignal mark of the royal favour, that he had liberty given to embattle it. The heralds expreſs this embattled line by the term *crenelle*; and when it has the embattling on both ſides, which is the more rare, they call it BRETESSE.

EMBER-*goose*, in *Ornithology*, the COLYMBUS *immer* of Linnæus, is larger than a common gooſe; its head is duſky; the back, coverts of the wings, and tail, are clouded with lighter and darker ſhades of the ſame; the pinnacles and tail are black; the under ſide of the neck marked with duſky ſpots; the breaſt and belly ſilvery, and the legs black. The ſkin is ſo tough, that it has been uſed in ſome of the northern countries as leather. This ſpecies inhabits the ſeas about the Orkneys; and in ſevere winters viſits the ſouthern parts of Great Britain. See DIVER.

This ſpecies of the wild gooſe is ſaid to hatch her young under her wings. The reaſon of this abſurd opinion is, that none ever ſaw her on the land, or out of the water, and that they have a cavity under one of their wings capable of containing a large egg. Phil. Tranſ. N° 473. 78.

EMBER-*weeks* are thoſe wherein the *imber*, or *embering-days* fall.

In the laws of king Alfred, and thoſe of Canute, thoſe days are called *ymbren*, that is, *circular days*, from whence the word was probably corrupted into *ember-days*. By the canoniſts, they are called *quatuor anni tempora*, the four cardinal ſeaſons, on which the circle of the year turns; and hence Heuſhaw takes the word to have been formed, viz. by corruption, from *tempora*, of *temporum*.

Mr. Somner thinks they were originally faſts, inſtituted to beg God's bleſſing on the fruits of the earth. Agreeably to which, Skinner ſuppoſes the word *ember* taken from the aſhes, *embers*, then ſtrewed on the head.

The *ember-days* are the Wedneſday, Friday, and Saturday, after Quadrageſima Sunday, or the firſt Sunday in Lent; after Whitſunday, after Holyrood day in September, and after St. Lucy's day in December; which four times anſwer well enough to the four quarters of the year, ſpring, ſummer, autumn, and winter.

Theſe *ember-weeks* are now chiefly taken notice of on account of the ordination of prieſts and deacons; becauſe the canon appoints the Sundays next ſucceeding the *ember-weeks* for the ſolemn times of ordination; though the biſhops, if they pleaſe, may ordain on any Sunday or holiday.

EMBERIZA, in *Ornithology*, a name, with the epithets of white and yellow, expreſſing the bunting and yellow-hammer. In the Linnæan ſyſtem this is a diſtinct genus of *paſſeres*, including a great number of ſpecies. For the general

general characters, see BUNTING. See also REED-*sparrow*, SNOW-*bird*, YELLOW-HAMMER, &c.

EMBLEM, ἐμβλημα, a kind of painted ænigma, which, representing some obvious history, with reflections underneath, inſtructs us in ſome moral truth, or other matter of knowledge.

The word is pure Greek, formed of the verb ἐμβαλλω, *to caſt in, to inſert*. Suetonius relates, that Tiberius cauſed the word to be erazed out of a decree of the Roman ſenate, becauſe it was borrowed from another language.

Such is that very ſignificant image of Scævola, holding his hand in the fire; with the words *operæ & pati fortia, Romanum eſt: to do and ſuffer couragiouſly is Roman*.

The *emblem* is ſomewhat plainer, and more obvious, than the ænigma. Gale defines *emblem* an ingenious picture, repreſenting one thing to the eye, and another to the underſtanding.

The Greeks alſo frequently gave the name *emblems*, ἐμβληματα, to *inlaid*, or *moſaic* works, and even to all kinds of ornaments of veſſel, moveables, garments, &c. And the Latins uſed *emblema* in the ſame ſenſe. Accordingly, Cicero, reproaching Verres with the ſtatues and fine wrought works he had plundered from the Sicilians, calls the ornaments fixed thereto (and which, on occaſion, might be ſeparated from them) *emblemata*. Add, that Latin authors frequently compare the figures and ornaments of diſcourſe to theſe *emblemata*: thus, an ancient Latin poet, praiſing an orator, ſays, that all his words were ranged like the pieces in moſaics,

ut teſſeræ omnes,
Arte pavimenti, atque emblemate vermiculata.

We do not uſe the Engliſh word *emblem* in this ſenſe; though the ancient juriſconſulti always retain the Latin *emblema* to expreſs ſuch ornaments; becauſe the Greek ἐμβλημα literally denotes any thing applied, or added to a body by way of enrichment.

With us, *emblem* ordinarily ſignifies no more than a painting, baſſo relievo, or other repreſentation, intended to hold forth ſome moral or political inſtruction.

What diſtinguiſhes an *emblem* from a *device* is, that the words of an *emblem* have a full, complete ſenſe of themſelves; nay, all the ſenſe and ſignification which they have together with the figure.

But there is yet a further difference between *emblem* and device; for a device is a ſymbol appropriated to ſome particular perſon, or that expreſſes ſomething which concerns him particularly; whereas an *emblem* is a ſymbol that regards all the world alike.

Theſe differences will be more apparent from comparing the *emblem* above quoted with the device of a candle lighted; and the words *juvando conſumor, I conſume myſelf in doing good*.

According to lord Bacon, *emblems* are of uſe in the art of memory, as ſenſible objects ſtrike the mind ſtronger than what is intellectual. Thus, it is eaſier to retain the image of a ſportſman hunting a hare, of an apothecary ranging his boxes, an orator making a ſpeech, a boy repeating verſes, or a player acting his part, than the correſponding notions of invention, diſpoſition, elocution, memory and action. Works abr. vol. i. p. 136. vol. ii. p. 475. and vol. iii. p. 106.

EMBLEMATICAL *character*. See CHARACTER.

EMBLEMENTS, Fr. from *emblaver*, q. d. *ſemer en blé, to ſow with wheat*, a term ſtrictly ſignifying the profits of lands ſown; though ſometimes uſed more largely for any profits ariſing, and growing naturally from the ground; as graſs, fruit, &c.

If a tenant for life ſow the land and die, his executor ſhall have the *emblements*, and not he in reverſion. But if the tenant for years ſow the land, and before ſeverance the term expires, there the leſſor, or he in reverſion, ſhall have the *emblements*, and not the leſſee.

The advantages of *emblements* are particularly extended to the parochial clergy by 28 Hen. VIII. cap. 11.

EMBOLIMÆAN and EMBOLISMIC, *intercalary*, is chiefly uſed in ſpeaking of the additional months which chronologiſts inſert to form the lunar cycle of 19 years.

The 19 ſolar years conſiſting of 6939 days, and 18 hours; and the 19 lunar years only making 6726 days; it was found neceſſary, in order to render the 19 lunar years equal to the 19 ſolar, which make the lunar cycle of 19 years, to intercalate or inſert ſeven lunar months, containing 209 days; which, with the four biſſextile days happening in that interval, make 213 days, and the whole, 6939 days. See CYCLE.

By means of theſe ſeven *emboliſmics*, or additional months, the whole 6939 days and 18 hours of the ſolar years are employed in the calendar.

In the courſe of 19 years there are 228 common moons, and ſeven *embolimic* moons. Their diſtribution is thus: every 3d, 6th, 9th, 11th, 14th, 17th, and 19th years, are *embolimic*, and conſequently contain 384 days a-piece.

And this was the method of computing time among the Greeks, when they uſed the ennedecaeterides, or cycle of 19 years. But they did not keep regularly to it, as the Jews ſeem to have done. The Greeks were followed by the Romans till the time of Julius Cæſar.

The *embolimic* months, like other lunar months, are ſometimes 30 days, and ſometimes only 29. See YEAR.

The *embolimic epacts* are thoſe between XIX and XXIX; which are thus called, becauſe, with the addition of the epact XI, they exceed the number XXX: or rather, becauſe the years, which have theſe epacts, are *embolimic*; having thirteen moons a-piece, whereof the 13th is the *embolimic*.

EMBOLISMUS, ἐμβολισμος, in *Chronology*, ſignifies *intercalation*.

The word is formed of ἐμβαλλω, *to inſert*. See EMBOLIMIC.

As the Greeks made uſe of the lunar year, which is only 354 days, in order to bring it to the ſolar, which is 365 days, they had every two or three years an *embolimus*, i. e. they added a thirteenth lunar month every two or three years; which additional month they called *embolimus*, ἐμβολιμος, becauſe *inſerted*, or *intercalated*.

EMBOLUS, the moveable part of a pump, or ſyringe; called alſo the *piſton*, and popularly the *ſucker*. See PISTON, PUMP, and SYRINGE.

The pipe, or barrel of a ſyringe, &c. being cloſe ſhut, the *embolus* cannot be drawn up without a very conſiderable force; which force being removed, the *embolus* returns again with violence. This phænomenon the Ariſtotelians attribute to nature's abhorrence of a VACUUM.

But the modern philoſophers finding, that in an exhauſted receiver the *embolus* is eaſily drawn up, though the orifice be ſtopped, prove that it is the preſſure of the atmoſphere on the external parts of the *embolus*, that makes the difficulty of drawing it up. See AIR, ATMOSPHERE, and SUCTION.

EMBOSSING, or IMBOSSING, the act of forming, or faſhioning works in relievo, whether they be caſt, or moulded, or cut with the chiſſel, &c.

Embоſſing is one great part of ſculpture; being that which has to do with figures raiſed, or prominent from the plain, or ground; the other part, which makes figures, &c. that are indented, or cut in below the ground, is called *engraving*. See ENCHASING.

EMBOWELLING *alive*, in *Law*, is part of the puniſhment of *High*-TREASON.

EMBRACE *a veit*, in the *Manege*, is uſed when a horſe, in working upon volts, makes a good way every time with his fore-legs. The oppoſite term to embracing a volt, is beating the duſt, which is putting his fore feet near the place from whence he liſted them.

Embracing the ground is uſed in the ſame ſenſe with *embracing the volt*. A horſe cannot take in too much ground, provided his croupe does not throw out; that is, does not go out of the volt. See BEAT.

EMBRACER, in *Law*, a perſon who, when a matter is in trial between party and party, comes to the bar with one of the parties (having received ſome reward ſo to do), and ſpeaks in the cauſe, or privately labours the jury, or ſtands there to overlook, awe, or put them in fear. The penalty hereof is twenty pounds, and impriſonment at the diſcretion of the juſtices.

EMBRACERY, in *Law*, the act or offence of embracers.

See EMBRACER.

EMBRASURE, in *Architecture*, an enlargement of the gap or aperture of a door, or window, within-ſide the wall. See DOOR.

Its uſe is to give the greater play, for the opening of the door, wicket, caſement, &c. or to take in the more light. The *embraſure* coming ſloping inwards, makes the inner angles obtuſe. When the wall is very thick, they ſometimes make *embraſures* on the outſide.

EMBRASURE, in *Fortification*, denote the holes, or apertures, through which the cannons are pointed; whether in caſemates, in batteries, or in the parapets of walls. See CANNON, ORDNANCE, BATTERY, &c.

The *embraſures* are generally about fifteen feet apart, from ſix to nine or ten feet wide without, and from two to three within. Their height from the platform is uſually three feet on the inſide, and a foot and half on the outſide; that ſo the muzzle, on occaſion, may be ſunk, and the piece brought to ſhoot low.

The beſt *embraſures* are thoſe made with a neck, whereby a part of the opening becomes more contracted, and conſequently is better adapted to preſerve the gunners and cannon from the enemy's ſhot, than when the cheeks of the *embraſures* are made ſtraight. It is moſt deſirable to have the axis of the *embraſure* at right angles to the length of the parapet, yet it may be ſometimes neceſſary to have them oblique. In this caſe the inſide of the parapet is notched, or cut away, ſo as to leave room for the front of the platform, that the wheels of the carriage

may be drawn up against the inner opening, for the axis of the gun to lie in the axis of the *embrasure*; and the outside of the parapet is to be strengthened, in order to compensate for that which is cut away within.

They are sometimes called *canonieres*, when big enough to pass the mouth of a cannon through: and *mousrieres*, when only big enough for musquets.

When the parapet is so low, that the cannon may shoot without *embrasures*, it is said to shoot *en barbe*.

EMBROCATION, or rather EMBROCHATION, EMBROCHE, ἐμβροχὴ, formed from βρέχω, *irrigo*, *I sprinkle*, or *moisten*, in *Pharmacy*, denotes the application of remedies, as oils, spirits, decoctions, and other liquids, by sprinkling, or even rubbing them on the part affected: this is also called *irrigation*.

Embrocations are only a kind of lotions; they are used to remove obstructions, and to relieve pains, numbness, and palsies. The pumping used in natural baths is properly an *embrocation*.

EMBROCATION, *gall.* See GALL.

EMBROIDERY, the enriching of a cloth, stuff, or muslin, by working divers figures thereon with the needle, and thread of gold or silver.

The word *embroidery* is derived from the French *broderie*, of *broider*, to *embroider*; which some deduce, by transposition, from *bordeur*, because they formerly *embroidered* only the borders of stuffs; whence the Latins also call the embroiderers, *limbularii*. Du-Cange observes, that they anciently wrote *aurebrisius* for *embroidered* with gold, or *brusius brudatus*, and *brudatus*; whence *broderie*.

That done with silk, flax, or the like, is not now called *embroidery*; though anciently, and properly, the word denoted all kind of figuring, or flourishing.

The chief use of *embroidery* is in church vestments, cloaths, housings, guidons, standards, &c. The invention of *embroidery* is attributed to the Phrygians; whence the Latins call embroiderers, *Phrygiones*.

The *embroidery* of stuffs is performed in a kind of loom; that of muslin is done by stretching it on a pattern already designed; the former kind is the most easy, but the latter admits of the greatest richness and variety. The thinnest muslins are the best for this purpose; and they are *embroidered* to great perfection in Saxony.

There are diverse kinds of *embroidery*; as *embroidery on both sides*, that which appears on both sides. *Gwimped embroidery*, performed either in gold or silver. In this work, a sketch is first made on the cloth, then they put on a cur vellum, and afterwards sew on the gold and silver with silk thread, interspersing silver and gold cord, tinsel, and spangles. *Embroidery on the stamp*, where the figures are very high and prominent, being supported on wool, cotton, hair, &c. *Lawn and plain embroidery*, where the figures are low and flat, and without any enrichment between them.

EMBRYO, in *Medicine*, the first beginning, or rudiments, of the body of an animal, in its mother's womb, before it hath received all the disposition of parts necessary to become animated; which is supposed to happen to a man on the forty-second day; at which time the *embryo* commences a foetus.

The word is derived from the Greek ἔμβρυον, which signifies the same thing; formed of the preposition ἐν and βρύω, *germino*, *pullulo*, *I spring out*; because of the manner of the first growth of the *embryo*, which resembles that of the first shoots of a plant, as being a kind of zoophyte, and having only a vegetative life.

The moderns have made abundance of fine discoveries on the formation and growth of the *embryo*.

M. Dodart, having an *embryo* of twenty-one days age put into his hands, made a nice examen thereof to find the order nature observes in the formation of the parts, and the first rise of the parts themselves.

The placenta he found more than half of the whole; and thence concludes, that the nearer the *embryo* is to the moment of its conception, the greater is the placenta with respect to the secundines, and the foetus; which circumstance furnishes a reason why miscarriages are more dangerous than regular deliveries; notwithstanding that the foetus in the former case is much less than in the latter. For though the *embryo* may have made a way sufficient for itself, it may not for so great a placenta, as is to follow it.

The *embryo* itself was only seven lines long, from the top of the head to the bottom of the spina dorsi, where it terminated. The thighs were not yet unfolded; they only appeared like two little warts at the bottom of the trunk; the arms made the same appearance on the shoulders. The head was just one-third of the length of the whole seven lines; on this were seen two little black points, which would have become eyes. The mouth was very big; which M. Dodart takes for an indication, that the foetus was fed by the mouth. There was no eminence for the nose; but two little, almost imperceptible, pits for the nostrils.

The painters usually make the head one eighth of the height of a well-proportioned man; and one-fourth of that of a young child: in the *embryo* we are speaking of, the head made one third part of the whole; whence it follows, that the younger the *embryo*, the bigger the head in proportion to the body. The parts nearer the head are also bigger in proportion to the rest; and the legs and feet the smallest.

The *embryo* was a little crooked forwards, and bore some resemblance to the maggot of a silk-worm; it weighed less than seven grains, which is an extraordinary lightness for a body seven lines long. It was so soft, that no part of it could be touched, without making a change in its figure.

Upon opening it, M. Dodart discovered the heart, and the right auricle; all the other parts in the thorax, and lower venter, were only simple lineaments, or outlines, and all vesicular, excepting a part on the left-side, which may be supposed to be the spleen. There was no appearance of any thing on the right side for a liver. Mem. de l'Acad. See FOETUS, and GENERATION.

EMBRYO is also used by naturalists to express the grain, or seed of a plant; sometimes the germ, or first sprout appearing out of the seed; because the whole future plant is supposed to be contained therein. Just as the whole chick is supposed to be contained in the cicatricula, or treddle of an egg.

EMBRYO-*worms*. It is a matter of no small curiosity, to observe the arrangement of the multitudes of the *embryo*-worms, as they are lodged in the bodies of the viviparous two-winged flies.

An accurate dissection of one of these little animals, shews very plainly the parts where the *embryo*-worms are enclosed. This dissection is easily made with a pair of fine pointed scissars, taking off the whole upper shell of the body from the lower; and that part which covers the belly may be turned back upon the corcelet, without disturbing the internal parts by the operation; and the form and arrangement of the parts which contain the *embryo*-worms in these, will be found very different from that of those which contain the eggs in the common flies. Baker on the Microscope, p. 115. 416, 417. 428. 470.

EMBRYONATUM *sulphur*, in the writings of some *Chymists*, the name of one of the three general classes of *sulphur* which they constitute. The first of these they call the universal *sulphur*, or resin of the earth; this is never united with any thing. By this they seem to mean what Boerhaave, and other late chemists, have called the vague acid. The second is this same sulphur united to metals and minerals; and the third is the same *sulphur*, when separated by art from these metals and minerals. This last seems *sulphur* in its most advanced state, and the second kind is what they call the *sulphur embryonatum*, as it is in the metals, &c. as an embryo-state, and ready to be disclosed into its last form.

EMBRYOTHLASTES, ἐμβρυοθλάστης, an instrument, wherewith to crush the bones of an embryo, or dead child; so as to make it easier of extraction, and prepare it for the embryulcus, to draw it out of the womb.

EMBRYOTOMY, ἐμβρυοτομία, formed of ἔμβρυον, and τέμνω, *I cut*, in *Surgery*, the operation of cutting off the funiculus umbilicalis, or navel-string, of a child just born, and tying it up.

EMBRYULCUS, in *Surgery*, the name of an instrument, in form of a sort of crotchet, or hook, used for drawing out the foetus in difficult labours. See FORCEPS.

EMBRYULKIA, or EMBRYULCIA, ἐμβρυουλκία, or ἐμβρυουλκία, formed of ἔμβρυον, *foetus*, and ἕλκω, *to draw*, in *Surgery*, an operation of extracting the child out of the mother's womb. See CAESAREAN.

What the Greeks call *embryulkia*, the Latins call *Cesarean section*; which latter name, M. Dionis observes, has taken place, and prevailed over the former; as being more easy of pronunciation.

EMENDALS, an old term still used in the accounts of the Inner Temple; where, so much *in emendals* at the foot of an account signifies so much in the bank, or stock of the house, for reparation of lodges, and other occasions.

EMENDATIO *panis & cervisiæ*, the assize of bread and beer; or the power of supervising and correcting the weights and measures belonging to them. See ASSIZE.

EMERALD, a precious stone, when in its greatest perfection green and transparent; and as to hardness nearly equal to the ruby. Its specific gravity is from 2,76 to 2,711.

The word is formed from the French *emeraude*, and that from the Latin *smaragdus*, which signifies the same. Others derive it from the Italian *smeraldo*, or the Arabic *zumrud*. Pliny reckons up twelve kinds of *emeralds*; and denominates each from the provinces, or kingdoms, where he supposed them to be found; as Scythian, Bactrian, Egyptian, Persian, &c.

But the modern naturalists and jewellers only know of two fine kinds, viz. Oriental and Peruvian. And if we

may credit Tavernier, in his treatise of coloured stones found in the Indies, inserted in the second volume of his Voyages, these two should be farther reduced to one, viz. the Peruvian.

In effect, he pretends that there is not, nor ever was, any mine of *emeralds* in the East Indies; and that all that are there found, were brought from Peru by the way of the South-sea; which was a method of commerce carried on by the Peruvians before the discovery of America by the Spaniards. But as the point of such commerce is not sufficiently proved, we must keep to the ancient division.

The Oriental *emerald* is harder, more brilliant, and transparent, than the Peruvian; which has generally clouds found in it, and sparkles less. Besides, that there are such quantities brought from Peru, by the way of Carthagena, that they are much sunk in value and reputation.

There are also European *emeralds*, but they are little other than coloured crystal.

Some authors say, that *emeralds* are usually taken out of iron mines; and Pomet assures us, he had one to which the iron ore was still sticking. To which, all we have to say, is, that it could not be a Peruvian, because there is no iron mine in the country.

The *emerald* is supposed to grow more and more perfect in the mine like the ruby; and to arrive at its greenness by slow degrees, as the fruit comes to maturity on trees. It is a common opinion, that the *emerald* grows in the jasper; and it is certain there are some jaspers so perfectly green and fine, that many have taken parts of them for *emeralds*.

But the proper matrix or marcasite of this stone is the *prasme d'oneraud*, which is held among the coarser precious stones; being hard, semi-pellucid, and often intermixed with yellow, green, white, and blue, &c.

The genuine *emerald* when in its most perfect state, is perhaps the finest and most beautiful of all the gems. It is found of various sizes, but usually small. Multitudes are met with of about the sixteenth of an inch in diameter, and they are found from this up to the size of a walnut. We have accounts of some of immense size among the ancients; but they were evidently not *emeralds* but jaspers, or other green stones. The large specimens at present are very scarce; and whether they are Oriental or Occidental, are of very great value.

The *emerald* is naturally of different figures, like the diamond, and many of the other gems. It is sometimes found in a roundish, or pebble-like form, but much more frequently in a columnar, or angular one, resembling common crystal. The pebble *emeralds* are always the hardest and brightest, but are seldom found exceeding the size of a pea, very rarely coming up to that of a horse-bean. The crystalliform usually grow several together, and are often considerably large. The pebble *emeralds* are found loose in the earth of mountains, and in the sands of rivers; the columnar are usually found adhering to, or bedded in a white, opake, crystalline matter, and sometimes to the jasper, or to the prasius; which last has been therefore called by some the mother of the *emerald*. By Mr. Bergman's analysis, 100 parts of *emerald* contain 60 of argill, 24 of silex, 8 of calcareous earth, and 6 of iron: and by that of Mr. Archard, 60 of argill, 21,66 of silex, 8,33 of calcareous earth, and 5 of iron.

The rough *emerald*, of whatever form, is usually of a very bright, and naturally polished surface, and is ever of a pure and beautiful green, without the least admixture of any other colour. It is of all the various shades of green, from the deepest to the palest, and doubtless is sometimes wholly colourless; but it is then esteemed a sapphire; all the harder gems, when colourless, being called by our jewellers *white sapphires*.

With a moderately strong heat the *emerald* becomes blue, but recovers its original green colour when cold. *Emeralds*, by being exposed to condensed solar heat, have been rendered white, and of various colours, and soon afterwards fused, by which operation they lost part of their weight and hardness. But Mr. d'Arcet could not fuse an *emerald* in the intense and long continued heat of a porcelain furnace, although the colour and transparency of it were thereby altered. *Emeralds* have the property of shining in the dark, after having been heated. They are the fourth in degree of hardness from DIAMONDS; and yet are susceptible of impression from a file. The Oriental *emeralds* are very scarce, and are at present found only in the kingdom of Cambay: very few of them have of late been imported into Europe, insomuch that some have supposed that there were in nature no Oriental *emeralds*; but within these few years some have been brought from Cambay into Italy, which greatly exceed all the American ones in beauty, as well as hardness.

The American *emeralds*, which as they are the finest that come to us, are called by our jewellers Oriental, are found principally about Peru, in the earth of some mountains. The European *emeralds* come principally from Silesia, though there are of them in other places; and the coloured crystals, which are what we usually meet with under the name of Occidental *emeralds*, are obtained from the mines of Germany.

The ancients made amulets of *emeralds* against all kinds of sorcery; and supposed them effectual against a thousand different diseases. At present, when we have more experience, or less credulity, they are valued for their beauty; not their virtues; though there are still some who suppose, that when reduced into an impalpable powder, and mixed with rose-water, they may be of some use in medicine.

We read in authors of several *emeralds* of incredible magnitude. Roderigo de Toledo tells us, that when the Saracens took that town, king Tarik had for his share of the plunder a table three hundred and sixty-five feet long, and all of a piece, which he maintains to be an *emerald*. After this, the reader will not wonder at that pretended to have been seen by Theophrastus, in a temple in Egypt, four cubits long, and three broad; nor even at an obelisk of *emerald* forty feet high. But these were not properly *emeralds* in our sense of the name, but only green marble, or other such stones.

In the Dictionnaire de Commerce, we have a very curious and accurate estimate of the values of the different kinds of Peruvian *emeralds*; which the reader will not be displeased to find transcribed here.

Those of the first and smallest sort, called *plaisters*, for printing, are worth 27 shillings sterling the mare, or 8 ounces. The demi-moitillons, as their name, are more. Good moitillons, which are only little pieces, but of fine colour, from 13*l.* to 15*l.* per mare. *Emeralds*, larger than moitillons, and called *of the third colour, or sort*, are valued at from 50*l.* to 60*l.* the mare. *Emeralds*, called *of the second sort*, which are in larger and finer pieces than the preceding, are worth from 65*l.* to 75*l.* per mare. Lastly, those of the first colour, otherwise called *negres cartes*, are worth from 110*l.* to 115*l.*

EMERALD, *ready cut, or polished, and set cut, being of good stone, and a fine colour, are worth,*

EMERALD, *counterfeit*. The manner of making *counterfeit emeralds* in paste is this: take crystal prepared, two ounces; common minium, or red-lead, four ounces; mix these well together, then add of good verdigrise two pennyweights, and crocus martis made with vinegar, eight grains. Mix all these well together, and set the whole in the hottest part of a potter's furnace, as long as the fire lasts. It must be put into a strong crucible, and covered with a lute. When it is cold take off the lute, and, if it is baked enough, it will be clear to the bottom; otherwise relute the pot, and put it into the furnace again. Twenty-four hours commonly is sufficient for making this: sometimes it requires a little more. The paste, thus made, is harder than ordinary, and is of a fine colour, and capable of a good polish. Neri's Art of Glass, p. 128.

If the paste be defired of a very deep *emerald* colour, take prepared crystal, one ounce; red-lead, six ounces and a half; of verdigrise, three penny-weights and thirteen grains; and of crocus martis, made with vinegar, ten grains. This requires a longer baking than the other, and is less hard, though of a deeper colour.

The proportions of these ingredients may be varied at pleasure, and the colour be made of all degrees of deepness; but the more lead is added the more baking is required, and, after all, the paste will be so much the softer.

EMERALD-*colour*, in the *Glass Trade*. The way of giving this beautiful dye to glass is this: in the pots of melted metal, made of polverine, and without manganese, when the matter is well purified, put a little crocus martis calcined with vinegar. About three ounces of this crocus is enough for a hundred weight of glass; let it stand till thoroughly mixed, then put into every hundred weight of metal two pound of calcined brass; this must be added at six different times, letting the metal stand two hours every time. When this is all in, make a proof of the metal; and if it has any bluishness, add more crocus martis, a small quantity at a time. When the whole is of a fine leek green, let it stand twenty-four hours to mix thoroughly, and then work it. Neri's Art of Glass, p. 51.

EMERALD, or EMERAUD, in *Heraldry*, is used in lieu of vert, or green, in blazoning the arms of dukes, earls, &c.

EMERGENT *year*, in *Chronology*, is the epocha, or date, whence we begin to account our time.

Our *emergent year* is sometimes the year of the creation; the Jews use that of the deluge, or the Exodus, &c. The *emergent year* of the Greeks was the establishment, or at least restoration, of the Olympic games by Iphitus. The Romans accounted their years from the building of the city, A. U. C. that is, ANNUS URBIS CONDITÆ. See EPOCHA.

EMERSION, in *Physics*, the rising of any solid above the surface of a fluid specifically heavier than itself, into which it had been violently immerged, or thrust.

It is one of the known laws of hydrostatics, that a lighter solid, being forced down into a heavier fluid, immediately endeavours to emerge; and that with a force, or moment, equal to the excess of a weight of a quantity of the fluid above that of an equal bulk of the solid.

Thus, if a solid be immerged in a fluid of double its specific gravity, it will emerge again, till half its bulk, or body, be above the surface of the fluid.

EMERSION, in *Astronomy*, is when the sun, moon, or other planet, begins to re-appear, after its having been eclipsed, or hid by the interposition of the moon, earth, or other body.

The difference of longitude is sometimes found by observing the immersions and *emersions* of the first of Jupiter's satellites.

The immersions are observed from the time of Jupiter's being in conjunction with the sun, to his opposition; and the *emersion*, from the opposition to the conjunction; which two intervals are usually six months a-piece, and divide the year between them.

But when Jupiter is in conjunction with the sun, and fifteen days before and afterwards, there is nothing to be observed; the planet, with its satellites, being then lost in the light of the sun.

EMERSION is also used when a star, before hid by the sun, as being too near him, begins to re-appear, and to get out of his rays.

EMERSION, *scruples*, or *minutes of*, an arch of the moon's orbit, as T Q, (*Tab. Astron. fig.* 46), which the moon's centre passes over, from the time the begins to emerge out of the shadow of the earth to the end of the eclipse.

EMERUS, in *Botany*. See *Scorpion* SENA.

EMERY, a sort of metallic stone, found in several mines of metals; but chiefly in those of iron, being properly an iron ore. *Emery*, says Mr. Kerwan (Elem. Min. p. 272) seems to be a mixture of the red and white calces of iron, with some unknown stony substance, perhaps tripoli: it scarcely yields in hardness to any substance except diamond; the best sort is of a dark, grey colour, but becomes brown and in great measure magnetic by calcination: other sorts are of a reddish rusty white, or yellowish colour: its specific gravity is from 3,000 to 4,000: it is never used as an iron ore, nor is its proportion of iron well known.

The word comes from the French *emeril*; formed from the Latin *smyris*, and that from the Greek σμυρις, which signifies the same thing; and which Lemery derives from the verb σμαω, *I clean, scour*.

We usually distinguish three kinds of *emery*; the Spanish, *red*, and *common emery*. The first is found in the gold-mines of Peru, and other provinces of the Spanish America; it is judged a kind of ore of that rich metal; being streaked with little veins, and specks of gold. It is for this reason the king of Spain prohibits its being exported, which renders it exceeding rare among us; to the great regret of the seekers of the philosophers stone, who have formed great hopes from the transmutation of this precious metal. The Spanish *emery* seems to be no other than the metal now called PLATINA; and the European *emeries* may probably participate of the same metal. The *red emery* is found in copper-mines; the little we have of it comes from Sweden and Denmark.

The *common emery* is taken out of iron mines; and is almost the only sort used among us. The consumption hereof is very considerable among the armourers, cutlers, locksmiths, glaziers, lapidaries, masons, &c. some of whom use it to polish and burnish iron, and steel works; others, to cut and scollop glass, marble, and precious stones.

This *emery* is of a brownish colour, sometimes bordering a little on red; exceedingly hard, and of consequence difficult to pulverize. The English are the only people that have acquired the art of making it into powder; which they do chiefly by means of certain mills contrived for that purpose; and thus send it in powder to their neighbours.

Portugal in its mortars *emery* in vain; it being so hard, that it would pierce or break the mortar before it would break itself.

Of the powder, the most subtile and impalpable is the best; as to the stone, it should be chosen of a high colour, and as free of the rock as possible.

Emery fused with lead, and iron, hardens them. It is also said to increase and heighten the weight and colour of gold. It is usual to mix a little of it with the gold from Madagascar, which is naturally pale and soft. See GOLD.

Emery is said to have a corroding and almost caustic quality; but this is without any just foundation. It is recommended by the ancients as an astringent and dentifrice. In this last intention, however, it must be used with great caution, as its hardness and sharpness are such, that it will be apt to wear off the enamel of the teeth.

EMERY, *powder of*, is a kind of a dirty matter, found on the lapidaries wheels; containing part of the powder of *emery* which they use.

EMETIC, from ἐμεω, *I vomit*, in *Medicine*, a remedy that excites vomiting; or that purges the stomach by the mouth.

Of these there is a great variety; as *ipecacuanha*, *carduus benedictus*, &c. The use of *emetics* is indicated by a foulness of the mouth in a morning, retching, loathing, gnawing of the stomach, gradual loss of appetite, spontaneous vomiting, &c.

Vomiting is raised by irritating the spirits with the presence of something loathed; by an unusual agitation, as falling, &c. by tickling the fibres of the fauces and pharynx with a feather dipped in oil; by drinking quantities of warm water, &c. by any thing sharp and viscous; as the flowers and seeds of dill, leaves of groundsel, &c. crocus, and glass of antimony; the flowers and regulus thereof; mercurius vitæ, mineral turbith, and mercury sharpened any way with acids.

The ancient physicians were very fond of *emetics*, as preservatives against diseases; and Hippocrates, in particular, has recommended the giving them twice a month, during winter, and in the spring. His *emetics* were very easy, simple, and gentle ones. One very common prescription, to this purpose, was a decoction of hyssop, with an addition of so much vinegar and salt as would make the patient nauseate it. This was to be taken by strong and robust people, in the morning, fasting, and, by the more weakly, after dinner or supper. Diodorus Siculus has assured us, that the great practice of the ancient Egyptian physicians consisted in glysters, vomits, and abstinence. Asclepiades, who was a great enemy to purges, yet often ordered his patients gentle vomits after supper.

The *emetic* medicines are of two very different kinds, some being naturally mild and gentle, others harsh and rough: of the former kind, warm water with butter, or the water of the naturally warm mineral springs, are often capable of doing very great service. The medicine of most general use at present, ipecacuanha, seems of a happy middle nature between these and the more rough ones, of which the vegetable kingdom affords us a great number, as asarabacca, white hellebore, gamboge, and all the purges in too large doses. The mineral world, however, affords much more numerous and more violent ones; such are all the preparations of copper, and of the vitriols, the antimonial vomits, and the mercurial ones.

The ancients, in violent diseases, such as madness, epilepsies, and some other disorders, not attended with a fever, gave the white hellebore root as an *emetic*, with great success; but we now use remedies less dangerous, as death has been sometimes known to have been the effect of this medicine. Our ipecacuanha is a celebrated remedy for fluxes: nor is the observation new, that vomits are the greatest of all remedies in these cases. Celsus, lib. ii. cap. 3. affirms, that vomits in general stop fluxes, yet always keep the body open. The country people, with us, frequently use asarabacca as a succedaneum for the ipecacuanha. It is rougher, indeed, than that medicine, but, if taken in decoction, the boiling carries off its acrid and too pungent quality, and it retains its *emetic* power in a more gentle degree, and, with it, has a balsamic and corroborating virtue, and has been known to cure inveterate quartans, and to do great service in jaundices and dropsies. Among the antimonial vomits, the best is the *emetic* tartar, prepared from the crocus metallorum, not from the glass of antimony, for that makes it doubly rough and harsh in its operation. Three or four grains of this alone, or yet less of it, mixed with ipecacuanha, are often given with great success; and when the intention is to purge and vomit at the same time, then three grains of this *emetic* tartar, added to a solution of manna, prove an excellent medicine. In asthmatic and pituitous cases, the oxymel of squills is a very efficacious and perfectly safe medicine; but all the preparations of copper, and the rougher antimonial vomits, are to be rejected, as being very dangerous and very uncertain, working either too little, or greatly too much, according to the state of the humours in the stomach. The stronger *emetics* before mentioned, as safe ones, are often necessary in cases of poison, especially of the nar-

cotic

cotic kind, and the infectious particles received from the effluvia of perſons in contagious diſeaſes, which being ſwallowed into the ſtomach with the ſpittle, would otherwiſe infallibly create the ſame diſeaſe. In diſorders ariſing from a vitiated or thick bile, formed, as it were, into a kind of viſcid coagulum, and ſtopping up the biliary ducts, as is the caſe in jaundices, and ſome other complaints, *emetics* are frequently uſed with great ſucceſs, after all the common methods have failed. In anaſarcas alſo and leucophlegmaſies, and œdematous ſwellings of the parts, and in a curable aſcites, *emetics*, exhibited in large doſes, uſually carry off by ſtool, though rarely by vomit, the aqueous ſerum from the liver, and the ducts and glands of the inteſtines, meſentery, and pancreas; nor are theſe the only caſes in which *emetics*, properly adminiſtered, are capable of doing very ſingular ſervice; but there ſtill requires great care and caution in giving them, as it is an infallible rule, that the medicine which can do great good, may alſo do great harm. Hoffm. Medic. Rational. Syſtem.

It is proper, in order to make *emetics* work the more eaſily, always to give them in a liquid form, or in a ſufficient quantity of ſome moiſtening, relaxing, and fatty vehicle; for vomiting not only requires a ſtrong contraction of the pylorus, and bottom of the ſtomach, but alſo a relaxation of the ſuperior orifice of the œſophagus. During the operation of *emetics*, and after it is over, the patient muſt be carefully guarded againſt the cold, and abſtain from all cold liquors, from all hot or ſtimulating medicines, and from all violent emotions of the mind; and about four hours after the operation of a vomit is over, it is extremely proper to drink half a pint of aſſes milk, if it can be readily had.

Whenever bleeding and vomiting are both neceſſary, bleeding ſhould always be done firſt.

The ancients in general, have recommended the giving of vomits in tertians and quartans, before the acceſs of the fit; and Alexander Trallian has been very earneſt in recommending them on this occaſion. The practice is highly conſonant with reaſon, and all the known rules, and may be of great advantage, not only in theſe, but in many other caſes, in which it is not at preſent thought of.

Dr. Harris has obſerved of the antimonial vomits, that they are very ſafe in the heat of ſummer, but very dangerous in colder ſeaſons. This author alſo recommends a decoction of the herb digitalis, or fox-glove, as a very ſafe, though powerful *emetic*; and there is an account of another plant uſually eſteemed of the dangerous kind, that is, the common creeping meadow-crowfoot, from which a very ſafe and efficacious *emetic* is to be prepared, that has been adminiſtered in many parts of England with great ſucceſs. The method of preparing it is only by diſtilling, in the common way, a ſimple water from the plant; this is very acrid and pungent to the taſte, and requires to be lowered, either by drawing a very large quantity from a little of the herb, or elſe by mixing common water with it. The method of giving it is this: let the patient drink about a quart of warm water, then give an ounce of this diſtilled water, and the whole will be immediately brought up with great eaſe; and the whole operation is then over for that doſe, and the water and medicine are again to be repeated as often as is judged neceſſary. Harris's Diſſertation.

If vomits operate too violently, common ſalt is a well known remedy. This ſeldom fails to check or ſtop them. Mild aromatics and opiates alſo have the ſame effect; and corroborating medicines, either taken internally, or applied by way of cataplaſm, or embrocation, to the region of the ſtomach.

Dr. Shaw thinks, the moſt ſafe, gentle, and agreeable *emetic* yet known, is an infuſion of the ipecacuanha-root in white wine, without heat. This is made by putting two drams of the root, in fine powder, into half a pint of white Liſbon wine, and, after ſtanding two days, adding a freſh quantity of wine to the remaining powder, when this is poured clear off. Theſe wines are to be mixed together, and given in a doſe ſuited to the ſtrength of the patient. This is greatly preferable to the vinum benedictum, *emetic* tartar, and all the medicines of a like kind, which are attended with danger and uncertainty in their operation; and while we have this, there is no reaſon why all the violent *emetics* ſhould not be wholly diſcarded from the practice of phyſic. Shaw's Lectures, p. 221.

The EMETIC *wine*, *vinum* EMETICUM, is only white-wine, wherein is infuſed ſome crocus metallorum, or glaſs of antimony.

Small doſes of *emetic* wine have been recommended as deobſtruent and ſudorific in low fevers, in many chronical diſeaſes, and eſpecially in an obſtinate rheumatiſm. See Medic. Eſſ. Edinb. abr. vol. i. p. 170. and Huxham. Obſ. de Aere & Morb. epidem.

The EMETIC *powder*, called alſo *powder of Algaroth*, from the name of its author, is a precipitate of antimony; or butter of antimony ſweetened and ſoftened by repeated lotions.

EMETIC *tartar*, is prepared from equal parts of crocus metallorum, and cream of tartar, boiled together in water, afterwards filtrated and cryſtallized. See CRYSTAL and TARTAR.

The operation of *emetic* medicines is thus accounted for by Dr. Quincy: the particles of the *emetic*, wedging themſelves into the orifices of the emiſſaries of the glands, placed adjacent to the ſurface of the ſtomach, do dilate the ſame (which by ſome extrinſic cauſe had been contracted); and after the ſame manner do diſſolve (at leaſt in ſome degree) the cohæſion of the ſtagnant morbific matter; rendering it more fluid, and conſequently making its reſiſtance leſs.

Now the natural and conſtant action of the glands being ſecretion, and the impediment by the dilatation of the orifice, and the attenuation of the fluid being taken away, or at leaſt made leſs than the natural momentum of the glands; the matter muſt naturally flow into the cavity of the ſtomach, till it be heaped up in ſuch quantity (which not being to be done in an inſtant, muſt require ſome time) as is ſufficient, by its ſtimulus, to vellicate and force the fibres of the ſtomach, abdomen, and diaphragm, by communication of the firſt with the two laſt, into a violent contraction, and thereby throw all out by the œſophagus; and this makes all quiet for a time, till a new and ſufficient quantity be excerned from theſe glands to produce the aforeſaid contraction.

Thus there happen fits of vomiting and quiet alternately, till either all the morbific matter be thrown out, or the force of the *emetic* be ſo diluted, that it is no longer able to draw out the morbific matter from the glands.

And the ſtrong contraction in ſo many muſcles, and muſcular canals, as are at work in the action of vomiting, and the violent conculſion which is produced all over the whole body by a power, which, by juſt computation, is not inferior to 26,000lb weight, may, and often does, take away the obſtruction in many other caſes, beſides thoſe which are adjacent to the ſtomach and gullet; as we plainly ſee by thoſe vaſt ſweats, which urgent fits of vomiting occaſion.

Emetic and purgative medicines differ only in this, that the particles of the latter do not immediately vellicate the fibres of the ſtomach, dilate the orifices, and attenuate the matter contained in the glands of the ſtomach; but act gently, and aſſiſt the natural motion of digeſtion, and ſo are carried down into the guts; and how they operate there, ſee PURGATIVE.

EMEU, in *Ornithology*, the common name of the CASSOWARY, a large kind of the oſtrich kind.

EMINENCE, in *Geography*, a little hillock, or ſweet, above the level of the adjoining champaign.

EMINENCE is alſo a title of honour given to cardinals.

The decree of the pope, whereby it is appointed, that the cardinals ſhould be addreſſed under the quality of *eminence*, bears date the 10th of January, 1630. They then laid aſide the titles of *illuſtriſſimi*, and *reverendiſſimi*, which they had before.

The grand maſter of Malta is likewiſe addreſſed under the quality of *eminence*.

The popes John VIII. and Gregory VII. gave the ſame title to the kings of France. The emperors have likewiſe borne it.

Eminentiſſimus, the ſuperlative of *eminent*, hath of late been attributed to the cardinals.

EMINENTIAL *equation* is uſed by ſome algebraiſts in the inveſtigation of the areas of curvilineal figures; for a ſort of artificial equation, containing another equation *eminently*. Hayes, Flux. p. 97.

EMINENTLY, EMINENTER, in the *Schools*, is uſed in contradiſtinction to *formally*, and in the ſame ſenſe with *virtually*, viz. to denote that a thing poſſeſſes, or contains, any other in a more perfect or higher manner than is required to a formal poſſeſſion thereof.

Thus an angel is ſaid to have prudence *eminently*; as he has it in a higher and more perfect degree than it is in man, in whom it is formally.

For one thing to contain another *eminently*, there are uſually required two conditions. 1. That the containing be of a more excellent nature than the contained. 2. That the leſs excellent be ſome way contained in the more excellent; viz. either as in its productive cauſe, or by ſome ſimilitude, or as to the manner and order of acting, &c.

EMIR, a title of dignity, or quality, among the Turks and Saracens, attributed to ſuch as are relations or deſcendants of their great prophet Mahomet.

The word is Arabic, and literally ſignifies *prince*. It is formed of the verb אָמַר, *amar*, which is originally

Hebrew ; and in both these languages signifies *to say*, and *to command*.

The *emirs* are held in high veneration, and have alone the privilege of wearing a green turban. On the borders of the Holy Land, there are several *emirs*, sovereign princes; as the *emir* of Gaza, and the *emir* of Terabeu, over whom the grand seignior has but little authority. The title *emir*, at first, was only given to the caliphs: in Persia they were also called *emir zadeh*, q. d. prince's son; whence by abbreviation of *emir*, they formed *mir*; and of *emir zadeh*, *mirza*. In after times, when the caliphs had assumed the title of sultans, that of *emir* remained to their children, as that of Cæsar did among the Romans.

At length, the same title of *emir* came to be attributed to all who were judged to descend from Mahomet by his daughter Fatimah, and who wear the green turban.

EMIR, is also a title, which being joined to some other word, frequently denotes an office or employ; as the *emir al umera*, *commander of commanders*, who, in the time of the caliphs, was chief of the councils and armies.

The appellation *emir* is also applied by the Turks to all viziers and bashaws, or governors of provinces. See BASHAW, &c. Add, that *emir akhor*, vulgarly *imrahor*, is master of the horse to the grand seignior.

Emir alem, vulgarly *emralem*, bashaw-bearer and director of all the standards of the empire.

Emir bahar, the prevoft, or superintendant of the market, who regulates the prices of provisions.

The *emir hagge*, or prince conductor of the pilgrims of Egypt to Mecca, is bashaw of Jerusalem, and is named yearly from Constantinople, though he is generally left two years in his office, to make amends for his great expence in equipage in the firft; and sometimes, if he has capacity and interest at the Porte, he is continued six years, but rarely longer; for if they conduct the caravan seven years, the grand seignior presents them with a collar of gold; and it is said, that their persons, after this, become sacred, and they cannot be publicly executed. This officer has command over the chiefs that govern Mecca. The perquisites of his office, beside what he is allowed by the Porte, consist in having a tenth of the effects of all the pilgrims who die in the journey. Pococke's Egypt, p. 165.

Emir al muslimin, or emir al muminin, i. e. commander of the faithful, or the believers, was a title assumed by the Almoravides and Almohades, who reigned in Africa and Spain.

EMISSARIUM, in *Antiquity*, a sloice, or drain, to draw off the water used in watering gardens, fields, &c.

EMISSARY, formed of *e* and *mitto*, q. d. *I send out*, a trusty, dexterous, able person, sent secretly, to sound the sentiments and views of another, to make him some proposal or overture; or to spread reports, watch the actions, motions, and countenance, of a contrary party or person, in order to make advantage of them all. See SPY.

The leaders of parties have abundance of emissaries employed in their service, who inform them of what passes everywhere, that they may take their measures accordingly.

EMISSARY *of a plant*, the same with *excretory duct*, being the common canal, or pelvis, in which all the little excretory tubes of a gland terminate.

EMISSION, the act of throwing, or delivering a thing, particularly a fluid, from within, outwards. The ancients took vision to be performed by the *emission* of visual rays from the eye.

But the term *emission* is chiefly applied among us, to the expulsion or EJACULATION of the seed.

EMITES, in *Natural History*, the name used by some authors for the *chernites*, a beautiful species of white marble, of which the tomb of Darius and many other of the great works of antiquity were made. It was valued for its fine polish.

EMMELIA, Εμμελεια, in *Antiquity*, a dance peculiar to tragedy, which had all the gravity and dignity that were suitable to the action then representing, and was designed to inspire the audience with sentiments of compassion and benevolence for the unfortunate and oppressed, with indignation against the guilty, and with the love of virtue, and abhorrence of vice.

The movements of such a dance as this must have been very solemn and majestic, and have bore a great affinity to the action of an orator; it was the only one, excepting the military dances, that had the approbation of Plato. Mem. Acad. Inscript. vol. ii. p. 160. See DANCE.

EMMENAGOGUES, Εμμηναγωγα, in *Medicine*, such remedies as promote the menses.

They are thus called from *ev*, *in*, *μην*, *month*, *αγω*, *duco*, *I lead*, because their natural periods of flowing are once a month.

Emmenagogues either act by giving a greater force to the blood in its circulation, whereby its momentum against the vessels is increased; or by making it thinner, whereby it will more easily pass through any outlets.

The former intention is helped by chalybeats, which give a greater weight and momentum to a languid heavy blood, and all other substances of the like gravity and elasticity; and such is the case of a leuco-phlegmatic habit, or, as it is commonly called, the green-sickness, and its cure.

But in the latter case, where the blood is florid, and too high, attenuating alteratives and excergents are the only remedies, because fitteft to render the blood more thin, and so give it such a property, as will better carry it through those little apertures destined for its discharge into the uterus.

EMMELEURE, in the *Manege*, a kind of composition of honey, and other ingredients, used for sprains and shoulder-splaits of horses. See CHARGE.

The word is French, derived from *miel*, *honey*, which is a part of the composition.

EMODIA, Αιμωδια, of αιμα, *blood*, and ωδη, *tooth*, in *Medicine*, a word used by some authors to express a plague of the teeth.

EMOLLIENTS, in *Medicine* and *Pharmacy*, remedies used to soften and loosen indurations or constrictions of the belly, or those of tumors and swellings: such are mallows, marshmallows, lily-roots, linseed, butter, wax, gum ammoniac, &c.

The *acrid emollient* is applied to external as well as internal remedies. We say, a laxative, anodyne, and *emollient* clyster; an *emollient* cataplasm, or *emollient* epithem, &c. Fresh cherries are an *emollient* food, though when dry, they rather constringe than relax, in wanting a great part of the phlegm which rendered them *emollient*. Ripe grapes, from being astringent, which they were before, become laxative and *emollient*. Hogslard, applied externally, is refolutive and *emollient*.

Quincy defines *emollients* to be such things as breathe and soften the asperities of the humors, and relax and supple the solids at the same time; for it is easy to conceive how these should be both effected by the same medicine, thus: by what means soever (whether in the stomach, or any other parts) the juices have obtained a sharpness or asperity, so as to vellicate and render uneasy the fibres and nervous parts, which often happens; those things which are smooth, soft, and yielding, cannot but wrap up their points, and render them imperceptible, whereby they may gradually, by the proper course of circulation, be brought to some convenient emunctory, without doing any injury by the way.

Such sharpness of parts, likewise, draws the fibres into spasms, keeps them too tense, and frequently thereby occasions obstructions of the worst kind.

In all such cases, therefore, *emollients* lubricate and moisten the fibres, so as to relax them into their proper dimensions; whereupon, such disorders cease.

EMOLUMENT, is properly applied to the profits arising daily from an office or employ.

The word is formed of the Latin *emolumentum*, which, according to some, primarily signifies the profits redounding to the miller from his mill; of *molo*, *molere*, *to grind*.

The patent, or other instrument, whereby a person is preferred to an office, gives him a right to enjoy all the dues, honours, profits, and *emoluments*, belonging thereto.

In our law-books, *emolument* is used in a somewhat greater latitude, for profit, or advantage, in the general.

EMPALEMENT, or IMPALEMENT, a cruel kind of punishment, whereby a sharp pole or stake, is thrust up the fundament, and through the body.

The word comes from the French, *empaler*, or the Italian, *impalare*; or rather, they are all alike derived from the Latin, *palus*, *a stake*, and the preposition *in*, *in*, *into*.

We find mention of impaling in Juvenal. It was frequently practised in the time of Nero, and continues to be so in Turkey.

EMPALEMENT, in *Botany*, denotes the cup, or outmost part of the flower of a plant, or that encompassing the foliation of the attire.

It is compounded of the three general parts of all plants, the skin, the cortical, and the woody bodies; each empales being (whether consisting of one or more pieces) of another leaf, and designed to be a guard and a band to the flower, where it is weak and tender; so that such plants as have flowers with a firm and strong base, as tulips, &c. have no *empalement*, nor need any. See CALYX.

EMPANELLING, or IMPANELLING, in *Law*, signifies the writing and entering into a parchment schedule, or

roll of paper, by the sheriff, the names of a jury summoned by him to appear for the performance of such public service as juries are employed in.

EMPARLANCE, or IMPARLANCE, in *Law*, a desire, or petition in court of a day to consider, or advise, what answer the defendant shall make to the action of the plaintiff.

The civilians call it *petitio indutiarum*. Kitchen mentions *emparlance general*, and *special*; the first seems to be only that made in one word, or in general terms; *emparlance special*, is where the party requires a day to deliberate, adding these words, *Salvis omnibus advantagiis tam ad jurisdictionem curiæ, quam ad brevia & narrationem*.

Briton also uses *emparlance* for the conference of a jury upon a cause committed to them.

EMPASMA, Εμπασμα, from ἐμπάσσω, *I sprinkle*, in *Pharmacy*, a powder thrown or sprinkled over the body, to correct some ill smell thereof, or to prevent unnecessary sweats.

EMPASTING, or IMPASTING, a term used in *Painting*, for the laying on of colours thick and bold, or applying several lays of colours, so that they may appear thick. See COLOURING.

It is formed of the French *empaster*, which has the same signification of *paste*, or *pâte*, *paste*.

A painting is said to be well empasted with colours, when the colours are bestowed plentifully, or it is well soaked, and saturated with colours.

The term is also used when the colours are laid distinct, and asunder, and not softened and lost in each other: e. g. this head is not painted, it is only empasted.

EMPATTEMENT, French, from *empatter*, *to thicken*, in *Fortification*, a term used by some to denote the same with TALUS.

EMPERESS, Empress, *Imperatrix*, the feminine of emperor, applied either to an emperor's wife, or to a woman who rules singly over an empire, with all the authority of an emperor; as the *empress* of Russia. See EMPEROR, QUEEN, &c.

EMPERESS, is also used in the *Ancient French Poetry*, for a particular kind of rhime, thus denominated by way of excellence.

The *rhime emperiere* was a sort of crowned rhime, wherein the syllable that made the rhime was immediately preceded by two other like syllables of the same termination, which made a kind of echo, called the *triple crown*; and which, to the shame of the nation (as some of their late authors express it) their best ancient poets took for a wonderful beauty and excellence.

Fa. Mourgues, in his treatise of French poetry, gives us an instance very proper to raise contempt of the miserable taste of that age, which knew no way of expressing that the world is impure, and subject to change, to excellent, as by saying,

Qu'est-ce qu'un monde, monde, enfin.

EMPERICHORESIS, see CIRCUMINCESSION.

EMPEROR, *imperator*, among the *Ancient Romans*, signified a general of an army, who, for some extraordinary success, had been complimented with this appellation. Thus Augustus having obtained no less than twenty famous victories, was often saluted with the title *emperor*; and Titus was denominated *emperor* by his army, after the reduction of Jerusalem.

Afterwards it came to denominate an absolute monarch, or a supreme commander of an empire; a Roman *emperor*, &c. In this sense Julius Cæsar was called *emperor*, and the title descended with the dignity to Octavius Augustus, Tiberius, and Caligula; and afterwards it became elective.

In strictness, the title *emperor* does not, and cannot add any thing to the rights of sovereignty; its effect is only to give precedence and pre-eminence above other sovereigns; and as such, it rather those invested with it to the summit of all human greatness.

The *emperors*, however, pretend, that the imperial dignity is more eminent than the *regal*; but the foundation of such prerogative does not appear: it is certain, the greatest, most ancient, and absolute monarchs, as those of Babylon, Persia, Assyria, Egypt, Macedonia, &c. were called by the name of *kings*, in all languages, both ancient and modern. See KING.

It is disputed, whether or not *emperors* have the power of disposing of the regal title. It is true, they have sometimes taken upon them to erect kingdoms; and thus it is that Bohemia and Poland are said to have been raised to the dignity; thus also, the *emperor* Charles the Bald, in the year 877, gave Provence to Boson, putting the diadem on his head, and decreeing him to be called *king*. *Ut more priscorum imperatorum regibus subjectur dominari.* Add, that the *emperor* Leopold erected the ducal Prussia into a kingdom, in favour of the elector of Brandenburg; and though several of the kings of Europe refused for some time to acknowledge him in that capacity, yet by the treaty of Utrecht, in 1712, they all came in.

In the East, the title and quality of *emperor* are more frequent than they are among us: thus, the sovereign princes of China, Japan, Mogul, Persia, &c. are all *emperors* of China, Japan, &c.

In the year 1723, the czar of Muscovy assumed the title of *emperor of all Russia*, and procured himself to be recognized as such by most of the princes and states of Europe.

In the West, the title has been a long time restrained to the *emperors* of Germany. The first who bore it was Charlemagne, who had the title *emperor* conferred on him by pope Leo III. though he had all the power before. The imperial prerogatives were formerly much more extensive than they are at present. At the close of the Saxon race, A. D. 1024, they exercised the right of conferring all the ecclesiastical benefices in Germany; of receiving the revenues of them during a vacancy; of succeeding to the effects of intestate ecclesiastics; of confirming or annulling the elections of the popes; of assembling councils, and of appointing them to decide concerning the affairs of the church; of conferring the title of king on their vassals; of granting vacant fiefs; of receiving the revenues of the empire; of governing Italy as its proper sovereign; of erecting free cities, and establishing rules in them; of assembling the diets of the empire, and fixing the time of their duration; of coining money, and conferring the same privilege on the states of the empire; and of administering both high and low justice within the territories of the different states: but in the year 1437, they were reduced to the right of conferring all dignities and titles, except the privilege of being a elector of the empire; of *jura primariæ*, or of appointing once during their reign a dignitary in each chapter, or religious house; of granting dispensations with respect to the age of majority; of erecting cities, and conferring the privilege of coining money; of calling the meetings of the diet, and presiding in them. Chiffel Abregé de l'Histoire d'Allemagne, p. 160 & 507.

To which some have added, 1. That all the princes and states of Germany are obliged to do them homage, and swear fidelity to them. 2. That they, or their generals, have a right to command the forces of all the princes of the empire, when united together. 3. That they receive a kind of tribute from all the princes and states of the empire, for carrying on a war which concerns the whole empire, which is called the *Roman month*. For the rest, there is not a foot of land, or territory, annexed to this title; but ever since the reign of Charles IV. the *emperors* have entirely depended on their hereditary dominions as the only source of their power, and even of their subsistence. See DIET and ELECTORS.

The kings of France were anciently also called *emperors*, at the time when they reigned with their sons, whom they associated to the crown; thus, Hugh Capet, having associated his son Robert, took the title of *emperor*, and Robert that of king; under which titles they are mentioned in the history of the council of Rheims, by Gerbert, &c. King Robert is also called *emperor* of the French, by Helgau of Fleury. Lewis le Gros, upon associating his son, did the same. In the first Register of the King's Charters, fol. 166. are found letters of Louis le Gros, dated in 1116, in favour of Raymond, bishop of Magueloune, wherein he styles himself *Ludovicus, Dei providentia, Francorum imperator Augustus.*

The kings of England had likewise anciently the title of *emperors*, as appears from a charter of king Edgar: *Ego Edgarus Anglorum basileus, totiusque regni insulanos accolas quos Britannicus circumgemit, &c. imperator & dominus.*

Add, that we say the king of England, *Omnem talem potestatem in regno pro quam imperator vindicat in imperio*, wherein the crown of England has been long ago declared in parliament to be an imperial crown.

EMPEROR, among *Hitherto Grammarians*, is an appellation given to a species of accents, serving to terminate a note completely, and answers to our point. See ACCENT.

EMPEROR *moth*, see ELECT.

EMPETRON, in *Botany*, a name by which some authors, as Dodonæus, &c. have called the kali or glass wort. Ger. Emac. Ind. 2. See KALI.

EMPETRUM, in *Botany*, see *Berry-bearing* HEATH.

EMPETRUM, is also a name used by some authors for the abrotanum, commonly called herb-terrible.

EMPHASIS, in *Rhetoric*, a force, stress, or energy, in expression, action, gesture, or the like, which performs the same office in sentences as the accent does in words. The word is Greek, ἔμφασις, which signifies the same. See ENERGY.

Some

Some consider *emphasis* as a figure whereby a thing is represented in the finest and strongest terms; *such*, e. gr. is that of Augustus, *Parum advertorum calefactum*; which is much more energetical, than if he had said, *Studiose multumque fuimus ante.*

The necessity of observing propriety of *emphasis* is so great that the true meaning of words cannot be conveyed without it.

Emphasis is of two kinds, simple, or complex. The former serves to point out the plain meaning of any proposition; the latter also marks some affection or emotion of the mind, by the use of which a discourse receives life and spirit, and is rendered capable of producing the noblest effects. See Sheridan's Lectures on Elocution, lect. 11.

EMPHATICAL, is used by the *Ancient Philosophers*, to express those apparent colours which are often seen in clouds before the rising, or after the setting of the sun; or those in the rainbow, &c.

These, because they are not permanent and lasting, they will not allow to be true colours; but, since these *emphatical* colours are light modified chiefly by refractions and with a concurrence of reflections, and some other accidental variations; *and since* they are the proper objects of sight, and capable as truly to affect it as other permanent colours are, there is no reason for excluding them from the number of true and genuine colours, since all other colours are only modifications of light, as these are.

EMPHEREPYRA, in *Natural History*, a genus of *siderochina*, composed of various crusts of coals, surrounding a nucleus of the same matter and structure with themselves. See SIDEROCHITA.

Of this genus we have five species. Hill's Hist. Fossils, p. 532.

EMPHRACTIC, in *Pharmacy*, the same with *emphractic*.

The word is formed from the Greek, ἐμφράττω, *I stop*.

EMPHRAXIS, in *Medicine*, an obstruction in any part.

EMPHRUE, in *Botany*, the name given by the people of Guinea to a species of tree, the leaves of which they boil in wine, and give as a great restorative in cases of weakness and decay. Its leaves are exactly of the shape of those of the common mulberry, but they are not indented at the edge. Petiver has thence called it *arbor Guinensis, mori folio non crenato*. Philos. Trans. N° 237.

EMPHYSEMA, ἐμφύσημα, from φυάω, *I inflate*, in *Medicine*, a windy swelling, or bloating, of the whole outer habit of the body, like that in the parts of divers animals when blown up, after they are killed.

This word, though appropriated by some writers to a soft tumor, arising from air contained in the cavities of the membrana cellulosa, is used by Hippocrates to express an inflation of the belly; and in some parts of his writings, in a more general sense, for any tumor.

The wind, or air, which is the matter of the *emphysema*, is lodged under the cutis, and principally in the cellular adipose.

Hence the seat of the *emphysema*, or the place wherein the wind is chiefly lodged, is in the adipose cells, under the skin covering the thorax. The ordinary occasion is some wound in the thorax, whereby the pleura is pierced, or the lungs are lacerated. Putridity is also a cause of this disorder, as is seen in mortifications of the external parts, and in many influences of putrid fevers.

Mr. Littre accounts for it thus: when a person is wounded in the breast, there enters air in at the wound: now, it may happen, either from the narrowness of the wound, or the flesh's closing again readily, or some other cause, that the air thus admitted cannot readily get out again, at least not all of it; and thus air comes to be enclosed in the capacity of the breast.

Now, at every inspiration, the lungs are to fill this capacity, by their swelling with the air which is naturally received; but here they cannot swell without pressing upon the other extraneous air: the consequence of which is, that this latter is made to slip between the interstices of the fleshy fibres, and perhaps to enter the little sæcula of the minutest veins, or lymphatics; immediately, another force comes to take place, contrary to that of inspiration, viz. expiration: in this, the breast contracting itself, presses the extraneous air still more than the lungs had done in their dilatation; and the two opposite moments, or actions, conspire to the same effect.

M. Mery and Dr. Hunter are of opinion, that the air is forced into the cellular membrane only during expiration.

The air, thus continually impelled, will be propagated along the passages it first opened for itself, till at length it meets, and becomes collected in some place: now this place must be the cellules of the fat, rather than anywhere else, because of the thinness and flexibility of their membranes; and as the air came from within the cavity of the breast, it will be in the fat that covers the breast under the skin, rather than elsewhere, that the wind, or tumor, or *emphysema*, will lie.

Now, such tumor cannot be very considerable, when only formed by the air received in at a wound; but if we suppose the wound to have pierced the substance of the lungs; then, besides the air taken in by the wound, there will be part of that taken by inspiration; so much as was contained in the bronchiæ, or vesiculæ, thus perforated or opened, escaping into the cavity of the breast, and driven along with the former into the flesh: and as a fresh quantity of this is supplied every moment, there will be a continual accession, so long as the wound of the lungs remains open.

Hence, an *emphysema*, from a wound in the lungs, sometimes possesses the whole habit, the air being carried to all the parts of the body.

M. Littre supposes, that the air of an *emphysema* from wounded lungs may be partly air taken up by the pulmonary vessels, and thrown from the arteries into the cellular membrane by a kind of secretion; but Dr. Hunter observes, that this is in the highest degree improbable; and that there is no occasion for having recourse to such winding and obscure passages.

When these tumors happen in putrid disorders, fomentations, with equal parts of sharp vinegar and rectified spirit of nitre, may be applied to them; but if they are caused by a wound, bleeding is necessary, which should be repeated whilst the breathing is quick and laborious: punctures, or small incisions may be made into the cellular membrane, or in different parts of the body, with a lancet; *by* which operation the air will be excluded, if the tumor is gently pressed. When the air is thus evacuated, a compress may be dipped in vinegar, and applied to the part which is supposed to be wounded: this may be secured by a tight bandage, and the patient ordered to lie on the injured side, in order to prevent a fresh influx of air. Internal suppurations may be prevented by nitre, and pectoral emulsions. When the air is lodged in the cavity of the breast, Mr. Hewson proposes to discharge it by a small opening made with a knife on the fore-part of the chest, between the fifth and sixth ribs, on the right side, because the integuments are thin; or between the seventh and eighth, or eighth and ninth ribs on the left side, to avoid wounding the pericardium. Mem. Acad. Sc. 1713. Lond. Med. Observ. &c. vol. ii. art. 2. p. 17, &c. and vol. iii. p. 28. 35. 372. 397.

EMPHYTEUSIS, in the *Civil and Canon Law*, the letting out of poor barren lands for ever, or at least for a long term of years, on condition of the tenants cultivating, meliorating, or mending them, and paying a certain yearly consideration.

The word is formed of the Greek, ἐμφύτευσις, which signifies *an engrafting*, and by metaphor, *a meliration* or *amendment*; for as we only graft trees to mend them, so a man only alienates his land by *emphyteusis*, on condition of having it amended.

Emphyteuses are a kind of alienations, differing from sales, in that they only transfer the *dominium utile*, the benefits of the ground, not the property, or fee-simple. Among the Romans they were at first temporary, afterwards perpetual.

The twentieth canon of the council of Carthage prohibits the bishops letting the church's *emphyteuses* out of the hands of private persons, unless they have been three years without paying rent.

EMPIRE, the territory or extent of land under the command and jurisdiction of an emperor. See EMPEROR.

We say, the Roman *empire*, the *empire* of the East, the *empire* of the West, or the western *empire*, the *empire* of the Great Mogul, &c.

Antiquaries distinguish between the medals of the *upper* and *lower*, or *less empire*: the curious only value those of the upper *empire*, which commences with Cæsar or Augustus, and ends in the year of Christ 260.

The lower *empire* comprehends near 1200 years, reckoning as low as the destruction of Constantinople, in 1453. They usually distinguish two ages, or periods, of the lower *empire*; the first beginning where the upper ends, viz. with Aurelian, and ending with Anastasius, including 200 years; the second beginning with Anastasius, and ending with the Palæologi, which includes 1000 years. See MEDAL.

In ancient history we read of four great monarchies or *empires*, viz. that of the Babylonians, Chaldæans, and Assyrians; that of the Medes and Persians; that of the Greeks; and that of the Romans. The first subsisted from the times of Nimrod, who founded it in the year of the world 1800, according to the computation of Usher, to Sardanapalus their last king in 3257, and consequently lasted about 1450 years. The *empire* of the Medes commenced under Arbace, in the year of the world 3257,

and

and was united to that of the Babylonians and Perſians under Cyrus, in the year 3468, and it cloſed with the death of Darius Codomannus in 3674. The Grecian *empire* laſted only during the reign of Alexander the Great, beginning in the year of the world 3674, and terminating with the death of this conqueror in 3681, his conquests being divided among his captains. The Roman *empire* commenced with Julius Cæſar, when he was made perpetual dictator, in the year of the city 708, and of the world 3956, forty-eight years before Chriſt. The ſeat of the *empire* was removed to Byzantium by Conſtantine, in the year of our Lord 334: the Eaſt and Weſt were then united under the title of the Roman *empire*, till the Romans proclaimed Charlemagne emperor, A. D. 800. From this epocha the Eaſt and Weſt formed two ſeparate *empires*; that of the Eaſt, governed by Greek emperors, commenced A. D. 802; and being gradually weakened, terminated under Conſtantine Paleologus in 1453. The Weſtern *empire* was afterwards known by the appellation of the *empire* or German *empire*.

EMPIRE, *or the* EMPIRE, uſed abſolutely, and without any addition, ſignifies the *empire* of Germany, called alſo in juridical acts and laws, *the holy Roman empire, S. R. I. q. d. ſacrum imperium Romanum*, which conſtitutes what we otherwiſe call the *Germanic body*.

The *empire* had its beginning with the ninth century: Charlemagne being created firſt emperor by pope Leo III. who put the crown on his head in St. Peter's church on Chriſtmas-day, in the year 800.

Authors are at a loſs under what form of government to range the *empire*; ſome of them will have it a monarchical ſtate, becauſe all the members thereof are obliged to aſk the inveſtiture of their ſtates of the emperor, and to take an oath of fidelity to him.

Others maintain it a republic, or ariſtocratic ſtate, becauſe the emperor cannot reſolve or determine any thing, without the concurring ſuffrages of the princes. It is added, that if they require inveſtiture from, and ſwear fealty to him, it is only as head of the republic, and in the name of the republic, and not in his own; juſt as at Venice, every thing is tranſacted in the name of the doge. See DOGE.

Laſtly, others will have the *empire* to be a monarcho-ariſtocratic ſtate, i. e. a mixture of monarchy and ariſtocracy; becauſe, though the emperor in many caſes ſeems to act ſovereignly, yet his decrees and reſolves have no force, in caſe the ſtate refuſe to confirm them.

In fine, we ſhould rather chooſe to call it an ariſtodemocratic ſtate, becauſe the diet, wherein the ſovereignty is lodged, is compoſed of princes, and the deputies of the cities; and is divided into three orders, or bodies, called *colleges*, viz. the college of electors, the college of princes, and the college of cities.

We ſay, diet of the *empire*, circles of the *empire*, fiefs of the *empire*, princes of the *empire*, eſtates of the *empire*, members of the *empire*, capitulations of the *empire*, receſſus of the *empire*, &c. See DIET, CIRCLE, PRINCE, CAPITULATION, and RECESSUS.

The ſtates, or eſtates of the *empire* are of two kinds, *mediate* and *immediate*. The *immediate* ſtates are thoſe which hold immediately of the *empire*, whereof, again, there are two kinds; the firſt, ſuch as have ſeats and voices in the imperial diet; the ſecond, ſuch as have none. The *mediate* ſtates are thoſe who hold of the *immediate*.

The ſtates which now compoſe the *empire* are the princes of the *empire*, the counts of the *empire*, the free barons of the *empire*, the prelates of the *empire*, the princeſſes or abbeſſes of the *empire*, the nobles of the *empire*, and the imperial cities.

EMPIRIC, a name given by antiquity to ſuch phyſicians, as formed to themſelves rules and methods on their own practice and experience, and not on any knowledge of natural cauſes, or the ſtudy of good authors; and who preſcribed, without enquiring into the nature of the diſeaſe, or the properties and virtues of their medicines; depending wholly on the authority of ſome general experienced remedies.

The word is formed of the Greek, ἐμπειρικὸς, and that of ἐμπειρία, *knowing, able*; but particularly knowing and learned by experience; the root being πεῖρα, *eſſay, or experiment*.

Medicine was almoſt altogether in the hands of *empirics* till the time of Hippocrates, who firſt introduced reaſon, and the uſe of theory therein: and hence there aroſe a new ſect, called *theoretics*.

Pliny relates, that the ſect of *empirics* had its riſe in Sicily; the firſt who profeſſed it, he ſays, were Apollonius and Glaucias; others ſay, Acron Agrigentinus. They and their followers made great oppoſition to the diſſection of human bodies; and particularly to that practiſed by Herophilus and Eraſiſtratus, on living bodies of criminals who were condemned to death: but the word *empiric* is now more odious than ever, being confounded with that of *charlatan*, or *quack*, and applied to perſons who practiſe phyſic at random, without a proper education, or underſtanding any thing of the principles of the art.

Indeed it is poſſible, the word may be abuſed even on this ſide of the queſtion; for thoſe of the phyſicians fervilely attached to the train and method of the ſchools, the reaſonings of Hippocrates and Galen, and the ſtatutes of the faculty, we all know, have been ever forward to treat thoſe who think more freely, and are leſs ſtrictly devoted to antiquity, cuſtom, and the reigning practice or mode, as *empirics*, charlatans, and quacks. See MEDICINE.

EMPIS, *in Natural Hiſtory*, the name given by authors to a large ſpecies of gnat, found about rivers and pools; it is diſtinguiſhed from all other kinds, by a circle of white ſpots round the middle of its body.

EMPLASTER, popularly called PLASTER, a medicine of a thick, glutinous conſiſtence, compoſed of divers ſimple ingredients, ſpread on leather, or linen, and applied externally.

The word is formed from the Greek, ἔμπλαστρον or ἔμπλασσω, *to put in a maſs, or to ſmear over*, becauſe the *emplaſter* is made of divers kinds of ſimple drugs, worked up into a thick tenacious maſs; or becauſe it covers over the piece of leather or linen to be applied on the part affected.

Emplaſters are made up in a ſtrong ſolid body, that by remaining a long time on the part, the medicinal ingredients they are chiefly compoſed of, may have time enough to produce their effect.

The drugs uſed to give a body and conſiſtence to *emplaſters*, are uſually wax, pitch, gums, fats, litharge, and other preparations of lead.

There are *emplaſters* of divers kinds, and uſed with divers intentions; ſtomachic *emplaſters*; cephalic, ſtyptic, hepatic, diaphoretic, reſolutive, detertive, emollient, incarnative, aſtringent, conglutinative, &c. *emplaſters*.

In the preſcription of extemporaneous *plaſters*, the greateſt regard is to be had to that particular conſiſtence which the part can moſt conveniently bear, whereupon the application is to be made. Thus, plaſters to the breaſt and ſtomach, eſpecially in the intention of emollients or diſcutients, ſhould be yielding and ſoft, as in the officinal *emplaſtrum ſtomachicum*; but to the loins, or any of the limbs, where warm diſcutients and ſtrengtheners are to be applied, an higher and more adheſive conſiſtence is to be ſought for. The emollient plaſters likewiſe ſhould be laid on thick, and frequently repeated, if the ſymptoms continue, becauſe their better parts are ſoon ſpent. Diſcutients alſo, applied to hard tumors, require repetition; but the ſtrengtheners, which are purſuitly contrived of a ſtrong adheſive conſiſtence, are permitted to lie on till they grow dry, and come off ſpontaneouſly. In ſome flatulent tumors, where *a plaſter* alone will not prevail, they are at intervals taken off, and diſcutient fomentations or lotions made uſe of; ſuch as are compoſed of bitters, carminatives, compounding alſo fixivial ſalts or alkaline ſpirits.

EMPLASTRUM *adheſivum, adheſive plaſter*, is prepared by melting together half a pound of the common plaiſter with a quarter of a pound of Burgundy pitch. The black ſticking-plaſter, called the lady's court-plaſter, is formed by diſſolving twelve ounces of the gum benjamin in twelve ounces of rectified ſpirit of wine, and ſtraining the ſolution. In a ſeparate veſſel, diſſolve a pound of the beſt iſinglaſs in five pints of pure water; and after ſtraining this ſolution, mix it with the former, and let them ſtand in a narrow veſſel, that the groſſer parts may ſubſide: when the liquor is cold, it will become a jelly, which will melt near the fire when it is to be ſpread. This quantity will be ſufficient for ſpreading on ten yards of half-yard wide ſilk; in order to which, the ſilk muſt be ſtretched in a frame, and the mixture may be ſpread upon it with a ſponge or brulh, which ſhould be done near a fire. As each ſpreading dried, it muſt be repeated to the tenth or twelfth time, and then touched lightly with the bruſh to give it a gloſs. The following more ſimple preparation may be ſubſtituted for the former: diſſolve a pound and a quarter of fine iſinglaſs in five pints of water, and before it cools ſpread it on ſilk in the manner above directed.

EMPLASTRUM *anodynum, anodyne plaſter*, is prepared by melting an ounce of the adheſive plaſter; and, whilſt it is cooling, mixing with it a dram of powdered opium, and the ſame quantity of camphor, previouſly rubbed up with a little oil. This plaſter gives relief in acute pains, eſpecially of the nervous kind.

EMPLASTRUM *attrahens, the drawing plaſter*, a plaſter ordered in the late London Pharmacopœia, to ſupply the

place of the melilot-plaster, in the dressing of blisters. The college are satisfied, that the herb is of no sort of use in the composition; and that very gross abuses are practised to give the green colour to the plaster; for which reason they have ordered the plaster to be now made in this manner: take yellow *resin*, and yellow wax; of each three pounds; tried mutton-suet, one pound: melt all together, and strain the mixture while it is hot. Pemberton's Lond. Disp. p. 351.

EMPLASTRUM *commune*, a name given in the new London Pharmacopœia, to what has been long called *diapalma-plaster*. The apothecaries had been long used to make this by a shorter way than has been prescribed them; and the college has now authorized that method, ordering it to be made of only a gallon of oil of olives, and five pounds of litharge, boiled together, with about a quart of water, to keep them from burning, till they are perfectly mixed, and have the consistence of a plaster. Pemberton's Lond. Disp. p. 352.

This plaster is generally applied to slight wounds and excoriations of the skin; it keeps the part soft and warm; and defends it from the air, which is all that is necessary in such cases.

EMPLASTRUM *ex ammoniaco cum mercurio*, a form of medicine in the new London Dispensatory, ordered to be prepared in the following manner:

Take gum ammoniacum, strained, a pound; quick-silver, three ounces; simple balsam of sulphur, a dram: rub the quick-silver with the balsam of sulphur till it no longer appears; then add by degrees the gum ammoniac melted, and almost cooled again, and make the whole into a plaster. Pemberton's Lond. Disp. p. 351.

This plaster is recommended in pains of the limbs, arising from a venereal cause. Indurations of the glands, and other violent tumors, are likewise found sometimes to yield to it.

EMPLASTRUM *gummi*, *gum-plaster*. Take of the common plaster, four pounds; gum ammoniac and galbanum, strained, of each half a pound; melt them together, and add six ounces of Venice turpentine. This is used as a digestive, and for discussing indolent tumors.

EMPLASTRUM *roborans*, the *strengthening-plaster*, a form prescribed in the London Dispensatory, and ordered to be made thus; take of the common plaster, two pounds; of frankincense, half a pound; of dragon's blood, three ounces; melt the plaster, and then add to it the other ingredients in powder. Pemberton's Lond. Disp. p. 358.

EMPLASTRUM *stomachicum*, *stomach plaster*. Take of gum-plaster half a pound; camphorated oil, an ounce and a half; black pepper, or capsicum, one ounce; melt the plaster, and mix with it the oil; then sprinkle in the pepper, reduced to a powder. An ounce or two of this plaster, spread on soft leather, and applied to the region of the stomach, will be of service in flatulencies, arising from hysteric and hypochondriac affections, a small quantity of the expressed oil of mace, or a few drops of the essential oil of mint, may be rubbed upon it before it is applied. Buchan's Domestic Med. p. 737.

EMPLASTRUM *vesicatorium*, *blistering plaster*. Take of Venice turpentine, six ounces; yellow wax, two ounces; Spanish flies, in fine powder, three ounces; powdered mustard, one ounce: melt the wax; and while it is warm, add the turpentine, taking care that it be not too much evaporated by heat. After the turpentine and wax are sufficiently incorporated, sprinkle in the powders, continually stirring the mass till it be cold. Buchan. p. 736. See BLISTER.

EMPLASTICS, in *Pharmacy*, are salves, or medicines, which stop up and constipate the pores of the parts they are applied on; otherwise called *emphractics*.

The word is formed from the Greek, ἐμπλασσειν, *to stop up*.

Such are fats, mucilages, wax, the whites of eggs, &c.

EMPLASTRA *emyntica*. See AMYNTICS.

EMPNEUMATOSIS, from ἐμπνεω, *I inflate*, in *Medicine*, a word used by some writers to signify an inflation of the stomach, but by others, in a more general sense, for inflations of the womb, or of any other part.

EMPORETICA *charta*. See CHARTA and PAPER.

EMPORIUM, in *Medicine*, is often used for the common sensory in the brain. See BRAIN.

EMPRIMED, among *Sportsmen*, a term applied to a hart, when he forsakes the herd.

EMPRION, from πριων, *a saw*, in the *Medical Writings of the Ancients*, a word used to denote a peculiar pulse, in which the artery is felt to be distended in one part more than another at every stroke, and by that means is made to resemble any serrated body, or the light teeth of a fine saw.

EMPROSTHOTONOS, in *Medicine*, a kind of tonic convulsion, wherein the head is drawn forwards, till the chin touch the breast.

The word is Greek, composed of εμπροσθεν, *before*, and τονος, *tension*, *stiffness*, of the verb τεινω, *I stretch*.

Sometimes too, it is so general, that the whole body is bent forward, and makes a kind of bow; and even sometimes a kind of circle, the knees meeting the head.

The cause of this disorder is a contraction of the anterior muscles, particularly those of the head, called *mystides*. See OPISTHOTONOS.

EMPTOR *familiæ*, *buyer of a family*, in the *Roman Law*, one who purchased the inheritance of a person, or the privilege of being appointed his heir by will.

This was done with the ceremony of scales and weights, before five witnesses, with the use of a peculiar formula of words.

Such *buyer* differed from the heir, *hæres*, as the testator in some measure alienated the right to the former during his own life-time, whereas the latter had only a right by his death. Brisson. de Formul. lib. iii. p. 585. Pitisc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

EMPTOR *fiduciarius*, *fiduciary buyer*, one who receives a thing in the way of pledge, till the money he has advanced be repaid. Salmat. de Mod. Usur. cap. 14. Pitisc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

EMPUSA, ἐμπουσα, among the ancients, a kind of hobgoblin, or bugbear, under the direction of Hecate, who used to send it to frighten people who laboured under misfortunes. Hofm. Lex. in voc.

EMPYEMA, in *Medicine*, a collection of pus, or purulent matter, in the cavity of the breast, discharged thither upon the burfting of fome abfcefs or ulcer in the lungs, or membranes that enclofe the breaft; or formed from that infpiffated ferum which Dr. Hunter obferves is found in large quantities in the cavities of the breaft, belly, &c. Lond. Med. Obf. &c. vol. ii. p. 61.

The word is formed of the Greek, εν, *in*, and πυον, *pus*, the letter *n* being here changed into *m*, a thing often done when the *n* happens to come in compofition before the labials *b*, *p*; as in the words *embamma*, *emblema*, *emperium*, &c.

The *empyema* fometimes fucceeds a quinfey, fometimes a peripneumony, but more ufually than either, a pleurify, as being ordinarily the effect of a peripneumonic or pleuritic abfcefs.

It ufually comes fifteen or twenty days after thofe diſeaſes. Sometimes, alfo, it is generated of extravafated blood, iſſued out of a burſten, broken, or putrefied vein; it is diſtinguiſhed by a difficulty of breathing, a dry cough, a heavinefs about the diaphragm, a noiſe, and fluctuating of the matter upon moving; a flow fever, ruddy cheeks, hollow eyes, the tips of the fingers hot, and a fwelling of the abdomen.

The cure is difficult, from the difficulty of abſorbing or evacuating fuch extravafated matter: if nature fhews any endeavour to throw it off by vomiting, or urine, or the like, the muſt be ſeconded, and aſſiſted therein. Thus, if the urine be purulent, adminiſter diuretics; if the ſtools, laxatives; if the ſpitting, expectorants, or even emetics; otherwiſe, recourſe muſt neceſſarily be had to a PARACENTESIS, or tapping.

In order to this, an aperture muſt be made in the thorax, by a proper inſtrument, on the ſide affected, between the third and fourth ſpurious rib on the right ſide; but on the left, between the ſecond and third, and about half or two-thirds of the diſtance from the ſternum to the vertebræ, becauſe here the muſcles are thinneſt, the artery is concealed under the rib, and the diaphragm is at a due diſtance; and through this the pus muſt be ſlowly drawn.

This operation takes its name from the diſeaſe, *empyema*.

There is alſo a kind of *ſpurious*, or *inflated empyema*, proceeding from a putulent, or ſerous humour, brought by ſome diſeaſe or paſſage into the thorax; where corrupting, it degenerates into a matter like pus.

An *empyema*, in courſe of time, breeds a phthiſis; and death is often the conſequence.

EMPYREUM, among *divines*, denotes the higheſt of the heavens where the bleſſed enjoy the beatific viſion; called alſo *empyreum heaven*, and *paradiſe*.

The word is formed of πυρ and ωον, *fire*, becauſe of its ſplendour.

EMPYREUMA, ἐμπυρευμα, in *Chemiſtry*, &c. a ſmell or taſte of burning; a quality, or change in bodies that have been burnt, or much ſcorched with fire, ſenſible to the taſte and ſmell; or perhaps it may be ſome extraneous matter impreſſed, or added by the fire, and remaining on the burnt or ſcorched part, that gives the new offenſive ſmell and flavour.

The word is formed of the Greek, ἐμπυρευειν, *to inflame*, *kindle*.

The term is chiefly uſed when in boiling or diſtilling any thing,

thing, it flicks and burns to the bottom of the veſſel, or alembic; the offenſive ſmell and taſte whereof are expreſſed by the word *empyreuma*. This term properly denotes a ſmell of burnt oils; and no other but oily ſubſtances can produce it; and it is peculiar to burnt animal and vegetable matters. The *empyreumatic* ſmell is therefore made a teſt of the exiſtence of oil in the ſubſtances which emit it.

EMPYREUMA, is alſo uſed for the heat remaining upon the declenſion of a fever.

EMRODS, or rather *Hæmorrhoids*. See HÆMORRHOIDS.

EMULATION, is a generous ardour kindled by the brave examples of others, which impels us to imitate, to rival, and, if poſſible, to excel them. This paſſion involves in it eſteem of the perſon whoſe attainments or conduct we emulate, of the qualities and actions in which we emulate him, and a deſire of reſemblance, together with a joy ſpringing from the hope of ſucceſs.

The word comes originally from the Greek, ἀμιλλᾶσθαι, *contiſi*, whence the Latin, *æmulus*, and thence our *emulation*.

Plato obſerves, of *emulation*, that it is the daughter of envy; if ſo, there is a great difference between the mother and the offspring: the one is a virtue, and the other a vice. *Emulation* admires great actions, and ſtrives to imitate them; envy refuſes them the praiſes that are their due; *emulation* is generous, and only thinks of ſurpaſſing a rival; envy is low, and only ſeeks to leſſen him.

Perhaps, therefore, it would be more juſt to ſuppoſe *emulation* the daughter of admiration: admiration, however, is a principal ingredient in the compoſition of it.

EMULGENT, in *Anatomy*, an epithet beſtowed on thoſe arteries which bring the blood to the kidneys, and thoſe veins which carry back what is ſuperfluous to the cava. See *Tab. Anat. (Angeiol.) fig.* 1. *n.* 49. *fig.* 6. *lit. t. t.*

The *emulgent* arteries ſpring from the deſcending trunk of the aorta; and the *emulgent* veins terminate in the aſcending trunk of the cava.

EMULSION, from *emulgere*, to *milk*, in *Medicine*, a ſoft liquid remedy, of a colour and conſiſtence reſembling milk. It is compoſed of oleaginous ſeeds, kernels, or fruits, gum-reſins, and gummy or reſinous juices, pounded in a mortar, and diſſolved in diſtilled waters, or light decoctions, and afterwards expreſſed, or ſtrained, and ſweetened with ſugar or ſyrup.

Emulſions ſerve to temper, dilute, and ſoften acrimonies of the breaſt; to moderate the heat of the kidneys; ſoften the ſharpneſs of the urine, and give the patient reſt and eaſe. They ſerve likewiſe as vehicles for certain ſubſtances which could not otherwiſe be conveniently taken in a liquid form. The common *emulſion* is made by blanching an ounce of ſweet almonds and a dram of bitter almonds, and beating them in a marble mortar; adding gradually the quantity of two pints of water, and ſtraining the liquid. If two ounces and a half of the mucilage of gum arabic are added to the almonds whilſt they are pounded in the mortar, we ſhall have the arabic *emulſion*. Theſe *emulſions* may be uſed as ordinary drink, in caſes which require ſoft cooling liquors. The camphorated *emulſion* is prepared by grinding half a dram of camphor, and half a dozen ſweet almonds together in a ſtone mortar, and adding by degrees eight ounces of mint water; ſtraining the liquor, and diſſolving in it half an ounce of white ſugar. A table-ſpoonful of this *emulſion* may be taken in fevers, and other diſorders which require the uſe of camphor, every two or three hours. The *emulſion* of gum ammoniac is made by grinding two drams of the gum with eight ounces of water poured gradually upon it till it is diſſolved.

This *emulſion* is uſed for attenuating viſcid phlegms, and promoting expectorations. In obſtinate coughs, two ounces of the ſyrup of poppies may be added to it. It may be adminiſtered in a doſe of two table-ſpoonfuls, three or four times a day. The oily *emulſion*, prepared by mixing ſix ounces of ſoft water with two drams of volatile aromatic ſpirit, and an ounce of Florence oil, and half an ounce of ſimple ſpirit, is ſerviceable in recent coughs; in more obſtinate coughs, it will be better to ſubſtitute for the aromatic ſpirit the paregoric elixir of the Edinburgh Diſpenſatory. A table-ſpoonful of it may be taken every two or three hours. Buchan's Dom. Med. p. 716, &c.

EMUNCTORY, from *emungere*, *to wipe away*, or *drain off*, in *Anatomy* and *Medicine*, a part of the body deſtined for the ſeparation of ſome humour judged uſeleſs, or even hurtful to the animal, after its having circulated ſome time with the blood.

The term *emunctory* alſo implies a cavity adjoining to the part that ſeparates, wherein the excrementitious humours is collected, and preſerved in readineſs for evacuation.

The kidneys, urinary bladder, and miliary glands of the ſkin, are *emunctories*; the parotides are not properly *emunctories*, becauſe deſtined to ſeparate the ſaliva, which is no uſeleſs or excrementitious humour, but neceſſary for the digeſtion of the food.

Some, without much propriety, confine *emunctory* to the receptacle into which the ſecreted excrement is diſcharged; as the pituitous humour of the brain into the noſtrils, the cerumen into the ears, the excrements into the inteſtines, &c. though theſe laſt have not undergone any circulation.

ENÆMON, Ἔναιμον, from αἷμα, *blood*, an external medicine which ſtops or ſtanches the blood; or which, by binding, cooling, or drying, cloſes the paſſages of the veſſels before open, or diminiſhes the fluidity and motion of the blood. See STYPTIC.

ENÆOREMA, Ἐναιώρημα, from αἴρω, *to exalt*, expreſſes ſuch contents of the urine as float about in the middle, reſembling a cloud; and thence alſo called NUBECULA. See URINE.

ENALLAGE, in *Rhetoric*, a figure whereby we change and invert the order of the terms in a diſcourſe, againſt the common rules of language.

The word is derived from the Greek, ἐναλλαγὴ, formed of ἐναλλάσσω, which ſignifies *to change*, as well as the ſimple verb ἀλλάσσω.

The grammarians, too, have a kind of *enallage*, whereby one part of ſpeech, or one accident of a word, is put for another.

Such is the change of a pronoun, as when a poſſeſſive is put for a relative, e. gr. *ſuus* for *ejus*: or of a verb, as when one mood or tenſe is put for another.

ENALURON, in *Heraldry*, is uſed by Guillim to expreſs a bordure charged with birds; as an *enaluron* of martlets, &c. but Mackenzie charges this as a miſtake ariſing from ignorance of the French tongue; *enaluré* properly ſignifying orle, or in manner of a bordure, and being applicable to a bearing of any thing in that form.

ENAMEL *of the teeth*. See TEETH.

ENAMEL, popularly AMEL, a kind of metalline colour, by the Latins called *encauſtum*; uſed in enamelling, and painting in *enamel*.

Enamels are glaſſes containing ſome opake ſubſtance, that is either unvitrifiable or incapable of being vitrified with the degree of heat requiſite for the fuſion of ordinary glaſs. They are generally compoſed of glaſs, mixed with metallic calces.

The common matter, which is the baſis of all *enamels*, is thus made: take fine lead, thirty pounds: and the ſame quantity of fine tin; calcine theſe together in a kiln, then ſift them; boil this powder in water, in clean earthen veſſels, and pour off the water, which will carry with it the finer part of the calx; put freſh water on the remainder, boil it again, and pour off in the ſame manner: do this ſo long as the water will carry off any part of the calx. Re-calcine the remaining matter, and waſh off its finer part in the ſame manner again, then evaporate all the waters which have waſhed off the finer calx, and keep the fire low towards the end of the operation, that the calx may not be waſted: this will be found at the bottom, of an extreme fineneſs.

Take of cryſtal frit, made with tarſo, and of this fine calx, each fifty pounds; white ſalt of tartar, eight ounces; powder and ſift theſe, and mix them well. Put this mixture into a new earthen-pot, give it a fire for ten hours, then powder it, and keep it in a dry covered place.

This is the common plain *enamel*, or matter of which all the other *enamels* are to be made. In making theſe, the following general cautions are neceſſary to be obſerved. 1. That the pots muſt be glazed with white glaſs, and muſt be ſuch as will bear the fire. 2. That the matter of *enamels* muſt be very nicely mixed with the colour. 3. When the *enamel* is good, and the colour well incorporated, it muſt be taken from the fire with a pair of tongs. 4. The general way of making the coloured *enamels* is this: powder, ſift, and grind all the colours very nicely, and ſift mix them well with one another, then with the common matter of *enamels*; then ſet them in pots in a furnace: and when they are well mixed and incorporated, caſt them into water; and when dry, ſet them in the furnace again to melt; and when melted, take a proof of them. If too deep coloured, add more of the common matter of the *enamel*; and if too pale, add more of the colour.

We may diſtinguiſh three kinds of *enamel*; the firſt intended for the counterfeiting and imitating of precious ſtones; the ſecond, for painting in *enamel*; and the third uſed by the enamellers, jewellers, and goldſmiths, on gold, ſilver, and other metals; with which laſt kind, particularly the white, it is that the makers of the Dutch ware give the groſs to their works.

The *enamels* uſed in imitating precious ſtones, and thoſe for painting, are uſually prepared by the workmen themſelves,

felres, employed in thofe arts; the reft are brought from Venice and Holland. The compofition is the fame in the main in all the three kinds; all the difference conſiſts in giving the colour or tranſparency.

ENAMELS *for painting.*

ENAMEL, *azure blue.* To make this, take of the common matter of *enamels*, four pounds; zaffer prepared, two ounces; brafs thrice calcined, or calcined copper, forty-eight grains: mix all theſe well together, and melt them in the furnace in the uſual way. Neri's Art of Glaſs, p. 150.

ENAMEL, *turquois blue*, is prepared by a mixture of ſix pounds of the baſis of *enamel*, with three ounces of calcined copper, ninety ſix grains of zaffer, and forty-eight grains of magneſia.

ENAMEL, *black.* To make the black *enamel*, take of the common matter of *enamels*, four pounds; tartar, four ounces; magneſia, two ounces: grind and mix theſe powders well with the matter of the *enamel*, then ſet them in a furnace in a large pot; when melted and refined, caſt them into water; and putting them again into the furnace, let them refine.

Or an excellent black *enamel* may be prepared by mixing equal quantities of magneſia, zaffer, and ſcales of iron, and adding one part of this mixture to fifteen or twenty of the baſis of *enamels*. Lewis's Com. Ph. Tech. p. 442.

ENAMEL, *the ruddy ſtream*, is made with flakes of vitriol, and ſal-petre, or with iron ruſt, well ground on an agat, with oil of ſpike.

ENAMEL, *green.* To make this, take of the common matter of *enamels*, four pounds; melt it, and caſt it into water; return it again to the furnace, and when purified, and braſs thrice calcined, or calcined copper, two ounces; crocus martis, made with vinegar, or ſcales of iron, forty-eight grains. Mix theſe firſt in fine powder, and put this in at three ſeveral times; when all is well incorporated, take it from the fire.

ENAMEL, *milk-white.* To make this uſeful colour in *enamels*; take of the common matter of *enamels*, ſix pounds; *magnaſium*, prepared, forty-eight grains; melt them in the furnace, caſt the whole into water, and afterwards return it again into the furface; and when refined, uſe it. See DELF-*ware*.

ENAMEL, *purple.* To make this, take of the common matter of *enamels*, ſix pounds; of magneſia three ounces; braſs, thrice calcined, or calcined copper, ſix ounces; mix all well together, and ſet them in a furnace, let them refine, then caſt them into water; return the matter to the furnace again, and when thoroughly melted, take it out for uſe.

This mixture, with a ſmall proportion of braſs, makes the red *enamel*.

Vermilion red is made with vitriol calcined between two crucibles, luted together; then waſhed in aqua fortis, and afterwards in fair water: the fire is to be moderate, and to remain about half an hour.

The *lake red* is compoſed of fine gold, diſſolved in aqua regia, with ſal ammoniac, or common ſalt. The diſſolution being completed, it is put in a cucurbit, with ſpring-water and mercury, over hot ſand for twenty-four hours. Some uſe a ſolution of pure block-tin, in aqua regia; and others crude tin, to precipitate the gold. The powder remaining at the bottom of the cucurbit, when the water is poured off, is ground up with double its weight of flower of ſulphur, and put in a crucible over a gentle fire; and when the ſulphur which takes fire, is exhaled, the red powder remaining is ground with *cocaille*.

ENAMEL, *violet-coloured.* The method of making the violet-coloured *enamel* is this: take of the common matter of *enamels*, ſix pounds; of magneſia, prepared, three ounces; of thrice calcined braſs, or calcined copper, forty-eight grains; mix the two powders well together; then mix the whole, put them into the furnace, and when refined, caſt them into water, return the water again to the furnace, and when refined take it out. Neri's Art of Glaſs, p. 157.

ENAMEL, *yellow.* To make this, take of the common matter of *enamels*, ſix pounds; of tartar, three ounces; of magneſia, ſeventy-two grains: mix all well together, and put them into the furnace in a large pot; when refined, caſt them into water, then return them to the furnace again; and when melted, take it out for uſe.

Laſtly, white copperas, calcined, makes a colour much like the amber-colour uſed by painters. See a Collection of Receipts for making ſeveral kinds of *Enamel* of different Colours and Teints in Daſſie's Handmaid to the Arts, vol. i. p. 336, &c. and Neri's Art of Glaſs, with Merret's Notes, and a Commentary by Kunkel, from which moſt of the above receipts are extracted.

ENAMELS, uſed by the *jewellers*, *goldſmiths*, and *enamellers*. Theſe, we have obſerved, come chiefly from Venice and Holland; they are in little thin cakes of different ſizes, uſually four inches in diameter, and half an inch thick. Every cake has the maker's mark ſtruck on it with a puncheon. The moſt uſual marks are the name Jeſus, a lion, monkey, ſun, &c.

Theſe brought from Venice are chiefly white, ſlate-colour, ſky-blue, carnation, yellow, green, and a deep blue, called a *paſſe azur*. Theſe ſeven are the principles of all the others, which ariſe out of the mixture of theſe; and the white, in particular, is, as it were, the baſis of all the other ſix principal colours.

White is made, as already obſerved, of cryſtal glaſs, tin, and lead, calcined by a reverberatory fire: and this *enamel* is uſed not only by the jewellers and enamellers on metal, but alſo by the painters in *enamel*, the makers of Dutch ware, &c. By adding azure thereto, it becomes a ſlate-colour; by adding copper and Cyprus vitriol, it makes a ſky-blue; by perigeux, a flefh-colour; and by iron-ruſt, a yellow: to make a green, they add copper-filings, &c.

ENAMELLING, the art or act of applying *enamels* of various colours on metals, &c. either in the way of painting, or by the lamp. It has been thought, that this is the ſame with the encauſtic painting of the ancients; but modern diſcoveries have evinced the contrary. See ENCAUSTIC *Painting*.

Painting in ENAMEL, is a method of painting with *enamels*, or metalline colours, ground, reduced to powder, and uſed like other colours with a pencil; then fuſed, taked again, and vitrified by force of fire.

The art of *painting in enamel*, or at leaſt of giving colours to glaſs, whence this method of painting was derived, is very ancient, and appears to have been firſt practiſed on earthen veſſels, or potters-ware. As early as in the age of Porſenna, king of Tuſcany, we hear of beautiful vaſes made in his territories, enamelled with various figures, though far ſhort of thoſe afterwards made at Faenza, and Caſtel Durante, in the duchy of Urbino, in the time of Raphael and Michael Angelo. There are ſtill ſome of thoſe vaſes extant in the cabinets of antiquaries; in all which, the deſign, or drawing of the figures, is much better than the colouring: for they were at that time only acquainted with two colours, viz. black and white, either for earthen or metal works, excepting a faint kind of carnation for the faces and other parts.

In the time of Francis I. of France, the art was retrieved in that country, particularly at Limoges, where there were produced abundance of very valuable pieces, in the manner of the ancients: that is, well performed as to the draught, and the clair-obſcure chiefly in two colours. There are two ways of *painting in enamel*; the one with clear and tranſparent, and the other with thick and opake colours. To uſe the firſt, they are only ground up with water; the ſecond are ground up with oil of ſpike. The firſt are laid on the metal flat, and bordered, or edged, with a rim of metal, to keep the colours aſunder; though we have ſeen pieces laid on contiguous, and without any partition, which is very difficult to paciifies, becauſe the tranſparent colours in melting are apt to run into each other, eſpecially in the ſmaller works.

The invention of opake colours is much later, and is greatly preferable to that of tranſparent ones. All metals, however, will not equally admit of both kinds: copper, for inſtance, which bears all the opake colours, will not bear the tranſparent ones; but to employ theſe latter upon copper, they are forced firſt to cover it with a layer or couch of black *enamel*; over which they lay a ſilver leaf, and on this apply the other ſuitable colours; that is, the colours or *enamels* proper for ſilver, which itſelf does not allow of all kinds.

Thoſe which ſuit it beſt are purple, green, azure, and aqua-marina; but gold receives all the kinds and colours, both opake and tranſparent, perfectly well. It muſt be obſerved, however, that only the fineſt gold muſt be uſed herein; for the tranſparent colours being laid on a baſe gold, grow dim and livid; there being a kind of ſmoke that ſettles on it, not unlike black lead.

Of tranſparent *enamels*, the hardeſt are always the beſt; though there is a difference even among theſe; ſome loſing their colour in the fire, and others retaining it. As to the reds, they are only red by accident, being yellow when made, and applied on the gold; and becoming red in the furnace. The beſt tranſparent reds are thoſe made of calcined copper, iron-ruſt, emplument, and calcined gold, melted, with the due proportions of ſand and ſalt of glaſs.

But it is the method of painting with opake or thick *enamels*, to which we owe all our fine modern pieces of *enamel*, particularly thoſe curious ones on gold, repreſenting portraits, to as much perfection as the beſt painting in oil; and even ſome hiſtory pieces; with this great advantage, that their beauty and luſtre never decay.

decay, being equally secure from injuries of time and weather.

This art we are indebted for to the French; nothing of the kind having been attempted before the year 1632, when James Toutin, a goldsmith, of Chasteaudun, and a great master in the common way of painting with transparent *enamel*, first applied himself to find a way to use thick colours of different tints, which should melt with fire, and yet retain their lustre, purity, &c.

Toutin succeeded in his attempt: and having got the secret, communicated it to his fellow-artists, who, in their turns, contributed to the bringing of it to perfection: the first who distinguished himself was Dubie, a goldsmith, who wrought in the galleries of the Louvre. After him came Moliere, a native of Orleans, who applied himself chiefly to the painting on rings and watch-cases. His disciple, Robert Vauquer, of Blois, exceeded them all, both in his designs and colours. After him, Pierre Chartier of Blois applied himself to the painting of flowers, wherein he succeeded to admiration.

By this time the English were fallen into the way; who, as is allowed by foreigners themselves, seem to have been the first who applied it with success to the painting of portraits.

M. Felibien observes, that the first, and most finished portraits, and those in the finest colours, were brought into France by Petitot and Bordier, from England. This occasioned Louis Hance and Louis de Guernier (two good painters in miniature) soon after to attempt the like; in which the latter succeeded beyond every body. He likewise invented several new tints for the carnations; and, had he lived, had probably merited the glory of carrying the art to its last perfection.

This kind of painting, to be in perfection, must be on plates of gold; for copper, beside that it emits a fume which tarnishes the colours, is apt to scale and crackle; and silver tarnishes the colours, though it is often performed on plates of copper, enamelled with the white *enamel*.

These plates are made a little hollow on one side, and raised on the other, either in a circular or oval manner, to prevent the gold's fretting by the fire, and making the colours crack and fly; nor must they be made too thick; it is sufficient they can bear the colours, though it is usual to strengthen them all round with a circle somewhat thicker.

The plate being hammered very evenly throughout, they apply a white *enamel* on both sides, though the design be only to paint on one of them; the intent of this is to prevent any swelling and warping by the fire: for, otherwise, in large pieces, and especially if the colours be laid on any thing unequally, they are apt to rise up in pufs or blisters. Now, this first lay, which is white, remaining smooth and uniform, serves as a ground for all other colours. The composition of the white *enamel*, with the other opake colours, is already delivered under the article ENAMEL.

The gold plate, thus enamelled in white, the draught or design to be painted must be chalked thereon, and afterwards the whole accurately drawn out in a ruddy brown. The draught or out-line thus finished, the piece is set to the fire, and then painted with the colours above prescribed.

The white ground they paint on serves all the colours for white: the method being to spare the ground, from first to last, in the places where the lights are to be, after the same manner as in miniature, though they have another white to lay over the other colours when there is occasion to raise them. Add, that as the painters in oil retouch their painting several times, and let them dry; so in this sort of painting they touch the piece as often as they please, setting it each time to a reverberatory fire, and taking it away again as soon as they perceive that the *enamel* has got its full polish.

The reverberatory fire is made in a little furnace, wherein there is fire both a-top and all round, on a void place in the middle, where the piece is to be put for the *enamel* to heal. The colours are laid on with the tip or point of the pencil as in miniature, with this only difference, that they use oil of spike to dilute them instead of gum-water. See MINIATURE.

The workers in *enamel* must be very cautious of the good or bad qualities of the oil of spike they employ to mix their colours with: it is a thing very subject to adulterations; sometimes with spirit of wine, sometimes with oil of turpentine. In the first case, it wants body, as there is usually too much spirit added; and in the latter, the smoak of the turpentine, when heated, spoils the colours. A small mixture of spirit of wine does well; and the best method for the nice artificer, is to refine the oil, and afterwards add to it such a quantity of spirit as *is found best*.

ENAMELLING *by the lamp, method of.* The works of this kind are all performed by the flame of a lamp; wherein, in lieu of oil, is put horse's grease, by some called caballine oil. The lamp is of copper, or whited iron, and consists of two parts, the box and the lamp; in the latter of these, which is a kind of flat oval, is put the oil, and out of these rises the wick: all the use of the box is to receive the oil, which the ebullition occasioned by the intense heat might throw abroad.

This lamp, or even where two or three artists work together, two or three more lamps, are placed on a table of a proper height, &c. under which, about the middle of its height, is a double bellows, like those of an organ, which one of the workmen raises and depresses with his foot to increase and quicken the flame of the lamp, which is by such means excited to a degree of vehemence almost incredible.

The wind of the bellows is conveyed to the several lamps, however many, by means of grooves cut along the thickness of the table, and covered with parchment, extending from the bellows, to a tube or pipe placed before each lamp. These tubes are of glass; and, that the enamellers may not be incommoded with the heat of the lamp, each tube is covered, at about six inches distance, with a piece of tin called a fan, which is fixed in a hole of the table. In works that do not take up much time, they content themselves with a glass blow-pipe to heighten the flame of the lamp.

Applying their cake of *enamel* to the flame of this lamp, they draw it out into threads inconceivably fine. Those made use of in artificial plumes of feathers are so very slender, that they may be wound on a reel like silk or thread.

The factitious sets of divers colours, sometimes used in embroideries, are also made of *enamel*, and that with so much art, that each piece has its hole to pass the silk through wherewith it is sewed. These holes are made by blowing them in long pieces, which are afterwards cut off with a proper tool. See the process of drawing out the *enamel*, illustrated under DUCTILITY *of glass*.

It is rare that the Dutch or Venetian *enamels* are used pure; the common way is to melt them in an iron ladle, with an equal quantity of glass or crystal; and when the two matters are in perfect fusion, they draw it out into threads of different sizes as occasion requires, by taking a quantity between two pipe-stopples held in the two hands, and removing them asunder as far as the arms will reach. If the thread is to be longer than the workman can stretch, a second person takes one of the ends, and continues to draw it out, while the first continues to keep the *enamel* to the flame. All the threads drawn after this manner are round; so that the nature of the work require them to be flat; they are afterwards drawn through a pair of pinchers while yet hot. They have another iron instrument, in manner of plyers, to draw out the *enamel* by the lamp, when it is to be worked or disposed in figures or otherwise. Lastly, they have glass tubes, of various sizes, serving to blow the *enamel* into various figures, and preserve the necessary vacancies therein, as also to spare the fluff, and form the contours.

When the enameller goes to work, he seats himself before his lamp, with his foot on the treddle, and holding in his left hand the piece of work he is to *enamel*, or the brass or iron wires his figures are to be formed with; with his right hand he draws out the thread from the *enamel* held to the lamp; and this is done with a dexterity and patience equally surprising.

There is nothing but may be thus represented in *enamel*; and there are figures so finely finished of this kind, that one would take them to have come out of the hands of the ablest sculptors.

ENARGIA, Ἐναργεια, in *Rhetoric*, a figure, which passing from the narrative style, points out, and as it were, sets the subject before the eyes of the audience. Voss. Rhet. lib. iii. p. 361.

ENARTHROSIS, Ἐναρθρωσις, a species of DIARTHROSIS. Such is that of the huckle-bone, &c. See ARTICULATION.

ENCÆNIA, Ἐγκαινια, a Greek term, signifying *restauration*, or *renovation*, being compounded of the preposition ἐν, and καινος, *new*.

ENCÆNIA, is more particularly used for the name of a feast celebrated by the Jews on the twenty-fifth of the ninth month, in memory of the dedication or rather purification of the temple, by Judas Maccabæus, after its having been polluted and plundered by Antiochus Epiphanes.

The Jews had also two other *Encænia*, viz. the dedication of the temple by Solomon, and that by Zorobabel, after the return from the captivity.

ENCÆNIA is likewise applied in the *Fathers*, and *Church-History*, to the *dedication* of Christian churches.

St. Auguſtine aſſures us, that in his time the uſe of the word *Encænia* was even transferred to profane matters; and that they called it *Encænium*, when they put on a new ſuit of clothes.

Our tranſlators of the Bible do not retain the word *Encænia*, in St John, x. 22. where mention is made thereof, in lieu of that, they call it *Feaſt of the Dedication*, which is leſs proper. In effect, it is not the feaſt of the dedication, but of the purification or re-conſecration of the temple profaned, that is there ſpoken of.

ENCAMPMENT, in the *Military*. See CAMP.

ENCANTHIS, in *Medicine*, denotes a tumor of the caruncula lachrymalis, in the great canthus, or angle of the eye.

The word is Greek, *εγκανθις*, formed of the prepoſition *εν* and *κανθος*, *corner of the eye*.

It is oppoſed to rhyas, which is a diminution or conſumption of the ſame caruncle. See RHYAS.

This tubercle grows either out of the caruncula lachrymalis, or from the adjacent red ſkin, and is ſometimes ſo large, as not only to obſtruct the puncta lachrymalia, but alſo part of the ſight, or pupilla of the eye itſelf. In this diſorder the tears continually run down the cheek, which not only greatly deform the eye and face, but often give riſe to an ophthalmy.

The *encanthis* is of two kinds, the one mild, and without hardneſs or pain, and the other malignant, livid, and painful; this laſt tends, in ſome degree, to a cancerous nature.

In the beginning of the mild *encanthis*, it is beſt to ſcarify, and apply a mild cauſtic; as burnt alum, or vitriol, mixed with ſugar. This powder muſt be ſprinkled into the tumor, and carefully waſhed out of the eye afterwards with warm milk or water; but, if this is not ſufficient, it may be carefully touched with the common cauſtic; and, to give a turn to the humour, internal medicines, as purges, and the like, muſt be given, and iſſues, or ſetons, muſt be made. Heiſter's Surgery, p. 343.

If theſe methods take no effect, and the tubercle is of a malignant kind, it is to be drawn out either with a hook, or a pair of plyers, or, if very large, by a threaded needle paſſed through it, taking hold of both ends of the thread, and gently riſing it till it can be cut off; but, in this, great care is to be taken not to wound the lacrymal caruncle. If the tubercle appear livid and cancerous, it is by all means to be let alone, as the irritating of ſuch with medicines is always of very bad conſequence.

The *encanthis* is occaſioned by a defluxion on that part, or an ulcer therein, not ſpeedily enough dried.

ENCARDION, from *καρδια*, *heart*, in *Botany*, a name given by the Greeks to what the Latins properly call the medulla in trees, the heart of the wood, or central hard part of the body.

ENCATHISMA, from *καθημαι*, *I ſit in*, in the *Medicinal Writings of the Ancients*, a term uſed to expreſs a ſort of bath, in which the patient was only to be plunged up to the belly.

ENCAUMA, from *καυμα*, *I burn*, in *Surgery*, a name given, by ſeveral writers, to the puſtule, or excoriation, owing to a burn. The ſame word is uſed alſo by ſome as the name of a peculiar kind of ulcer in the eye. Actius ſays, that the ſuperficial exulcerations of the eyes, which are owing to defluxions of humours, are called, by the authors who wrote in early times, by three names, according to their differences. 1. A *caligo*: this is a ſuperficial ulcer, of a bluiſh colour, formed in the black of the eye, and covering moſt of it; when the pupil itſelf is affected by this, the ſight is uſually much impaired. 2. The *nubecula*: this was a ſmaller, deeper, and whiter ulcer, formed alſo in the black of the eye. 3. The *epicauma*: this was a roughneſs of the whole black of the eye, in which it appeared parched, or burnt, and was of a greyiſh colour over the entire ſurface. 4. The laſt of theſe diſorders was the *encauma*; by this name they expreſſed an ulcer, which produced an impure and ſolid cruſt, either in the black or white of the eye, and uſually was produced by a fever. And the corroſion of the matter of this ſort of ulcer was ſo ſharp, that the coats of the eyes were not unfrequently eaten through, and the humours fell out. Actius, Tetrabibl. 2. cap. 3.

ENCAUMA, in the *Old Writers on Medicine*, is alſo uſed to expreſs the eſcar of a fever.

ENCAUSTIC *Painting*, *Encauſtum*, from *καιω*, *ουσω*, *I burn*, or, in a ſpecies of painting with burnt wax, practiſed by the ancients, and lately revived. Pliny has given the following brief account of the invention and nature of this art: *Cerâ pingere ac picturam inurere, quis primus excogitaverit, non conſtat: quidam Ariſtidis inventum putant, poſtea conſummatum a Praxitele; ſed aliquanto antiquiores encauſticæ picturæ extitere, ut Polygnoti, & Nicanoris, & Aristolai, Patrium. Leſa put quoque, Equæ, picturæ ſua inſcripſit Timarco; quod profecto non feciſſet, niſi encauſtica ſecuta. Pamphilus quoque Apellis præceptor non pinxiſſe tantum encauſtica, ſed & cum docuiſſe traditur Pausium, Spectatum primum in hoc genere nobilem.* Lib. xxxv. cap. 11. From this paragraph we learn, that the method of painting in wax, and burning in the picture, was very ancient; nor is it improbable that in former times, when they were unacquainted with dry oils, and tranſparent varniſhes, they ſhould make uſe of this method for preſerving their colours from damps and heats; though ſome imagine, that by *cera* is meant a compoſition, different from wax, and capable of bearing the fire; and that burning the picture denotes merely enamelling. Pliny in the ſame chapter informs us, that there were anciently two methods of *encauſtic* painting in uſe: *Encauſto pingendi duo fuiſſe antiquitus genera conſtat, cerâ & in ebore, cestro, i. e.* viriculo; *donec claſſes pingi cœperi. Hoc tertium acceſſit, reſolutis igni cœris, penicillo utendi; quæ pictura in navibus non fallit, nec ſole, nec ſalſo corrumpitur.* Dr. Parſons maintains, that the *cauſtrum* was a pointed tool uſed in modelling or carving upon ivory or wax; and he ſuppoſes that there is a contraſt between the uſe of the *cauſtrum*, and painting ſhips with a brush, and therefore that the term *pingendi* cannot be underſtood to mean the laying on of paint. However, there is a paſſage in Vitruvius, lib. vii. cap. 9. which ſeems to aſcertain the nature of the ancient *encauſtic* painting. *Ab ſi quis ſubtilior fuerit, & vitrearii expoſitionem minuiſcant ſuum colorem retinere*, &c. i. e. if any one is more wary, and would have the poliſhing, or painting, with vermilion hold its colour, when the wall is painted and dry, let him take Carthaginian wax, melted with a little oil, and rub it on the wall with a hair-pencil; and afterwards let him put live coals into a chafing-diſh, and hold it cloſe to the wax; when the wall, by being heated begins to ſweat, let it be made ſmooth; afterwards let him rub it with a candle, and clean linen rags, in the ſame manner as they do the naked marble ſtatues. This the Greeks call *καυσις*. The coat of Carthaginian wax is ſo ſtrong, that it neither ſuffers the moon by night, nor the ſun-beams by day, to deſtroy the colour. From this paſſage we learn the ancient method of painting in wax by inuſtion, more obſcurely expreſſed by Pliny; though Pliny, in another paſſage, expreſly informs us, that they uſe coloured wax: *Ceræ* (he ſays) *tinguntur iiſdem his coloribus, quæ inuruntur*; that they employed a pencil to lay on the melted wax; *reſolutis igni cœris, penicillo utendi*; that the picture was fixed by inuſtion, *picturam inurere*. And we learn from Vitruvius, that the whole was cleaned and poliſhed with linen rags. This ancient art, after having been long loſt, was reſtored by count Caylus, a member of the Academy of Inſcriptions in France; and the method of painting in wax was announced to the Academy of Painting and Belles Lettres, in the year 1753; though M. Bachelier, the author of a treatiſe De l'Hiſtoire & du Secret de la Peinture en Cire, had actually painted a picture in wax in 1749; and he was the firſt who communicated to the public the method of performing the operation of inuſtion, which is the principal characteriſtic of the *encauſtic* painting. The count kept his method a ſecret for ſome time, contenting himſelf with exhibiting a picture at the Louvre in 1754, repreſenting the head of Minerva, painted in the manner of the ancients, which excited the curioſity of the public, and was very much admired. In the interval of ſuſpence, ſeveral attempts were made to recover the ancient method of painting. The firſt ſcheme adopted was that of melting wax and oil of turpentine together, and uſing this compoſition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as the wax is not burnt in this way of managing it. In another attempt, which was much more agreeable to the hiſtorian's deſcription of *encauſtic* paluting, the wax was melted with ſtrong lixivium of ſalt of tartar, and with this the colours were ground. When the picture was finiſhed, it was gradually preſented to the fire, ſo as to melt the wax; which was thus diffuſed through all the particles of the colours, ſo that they were fixed to the ground, and ſecured from the acceſs of air or moiſture. But the method of count Caylus is much more ſimple: the cloth, or wood, which he deſigned for the baſis of his picture, is waxed over, by only rubbing it ſimply with a piece of bees-wax; the wood or cloth, ſtretched on a frame, being held horizontally over, or perpendicularly before a fire, at ſuch a diſtance, that the wax might gradually melt, whilſt it is rubbed on, diffuſe itſelf, penetrate the body, and fill the interſtices of the texture of the cloth, which, when cool, is fit to paint upon: but as water-colours, or thoſe that are mixed up with common water, will not adhere to the wax, the whole picture is to be firſt rubbed over with Spaniſh chalk or white, and then the colours are applied to it: when the picture is dry, it is put near the fire, whereby the wax melts, and abſorbs all the colours.

M. J. H. Muntz, in a treatiſe on this ſubject, has propoſed

posed several improvements in the art of *encaustic* painting. When the painting is on cloth, he directs it to be prepared by ſtretching it on a frame, and rubbing one ſide ſeveral times over with a piece of bees-wax, or virgin's wax, till it is covered with a coat of wax of conſiderable thickneſs. In fine linen, this is the only operation neceſſary previous to painting; but coarſe cloth muſt be rubbed gently on the unwaxed ſide with a pumice ſtone, to take off all thoſe knots, which would prevent the free and accurate working of the pencil. Then the ſubject is to be painted on the unwaxed ſide with colours prepared, and tempered with water; and when the picture is finiſhed, it muſt be brought near the fire, that the wax may melt and fix the colours. This method, however, can only be applied to cloth, or paper, through the ſubſtance of which the wax may paſs; but in wood, ſtone, metals, or plaiſter, the former method of count Caylus muſt be obſerved.

Mr. Muntz has alſo diſcovered a method of forming grounds for painting with crayons, and fixing theſe, as well as water-colours, employed with the pencil. On the unwaxed ſide of linen cloth, ſtretched and waxed as before, lay an even and thick coat of the colour proper for the ground: having prepared this colour, by mixing ſome proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire that the wax may melt, paſs through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was firſt rubbed on ſhould not be ſufficient for the body of colour; but as this muſt be laid on without heat, the wax ſhould be diſſolved in oil of turpentine, and applied with a braſh, and the canvas be again expoſed to the fire, that the freſh ſupply of wax may paſs through the cloth, and be abſorbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth muſt be firſt fixed to the ſtraining frame: and then the paper muſt be paſted to it with a compoſition of paſte made with wheaten flour, or ſtarch and water, and about a twelfth part of its weight of common turpentine. The turpentine muſt be added to the paſte when it is almoſt ſufficiently boiled, and the compoſition well ſtirred, and left to ſimmer over the fire for five or ſix minutes; let wax be diſſolved in oil of turpentine to the conſiſtence of a thin paſte; and when the cloth and paper are dry, let them be held near a fire; and with a braſh lay a coat of the wax and turpentine on both ſides the joined cloth and paper, in ſuch a degree of thickneſs, that both ſurfaces may ſhine throughout without any appearance of dull ſpots. Then expoſe the cloth to the fire or to the ſun; by which means the oil will evaporate, and the wax become ſolid, and be fit to receive any compoſition of colour for a ground, which is to be laid on as above directed in the caſe of cloth without paper.

Almoſt all the colours that are uſed in oil-painting may be alſo applied in the *encaustic* method. Mr. Muntz objects, indeed, to brown, light pink, and unburnt *terra di Sienna*; becauſe theſe, on account of their gummy or ſtony texture, will not admit ſuch a cohesion with the wax as will properly fix them; but other colours, which cannot be admitted in oil-painting, as red-lead, red orpiment, cryſtals of verdigriſe, and red precipitate of mercury, may be uſed here. The crayons uſed in *encaustic* painting are the ſame with thoſe in the common way of crayon painting, excepting thoſe that in their compoſition are too tenacious; and the method of uſing them is the ſame in both caſes.

The *encaustic* painting has many peculiar advantages; though the colours have not the natural varniſh or ſhining which they acquire with oil, they have all the ſtrength of paintings in oil, and all the neatneſs of water-colours, without partaking of the apparent character or defects of either; they may be looked at in any light and in any ſituation, without any falſe glare; the colours are firm, and bear waſhing; and a picture, after having been ſmoaked, and then expoſed to the dew, becomes as clean as if it had been but juſt painted. It may alſo be retouched at pleaſure, without any detriment to the colours; for the new colours will unite with the old ones, without ſpots, as is the caſe in common freſco painting; nor is it neceſſary to rub the places to be retouched with oil, as in oil pictures; it is not liable to crack, and eaſily repaired, if it ſhould chance to ſuffer any injury. The duration of this painting is alſo a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corroſive ſubſtance injure them; nor can the colour fall off in ſhivers from the canvas. However, notwithſtanding all theſe and other advantages enumerated by the abbé Mazeas, and Mr. Muntz, this art has not yet been much practiſed. Many of theſe properties belong to a much higher ſpecies of *encauſtic* painting lately diſcovered in England, the colours of which are fixed by a very intenſe heat; nor are the colours, or grounds, on which they are laid, liable to be diſſolved or corroded by any chemical menſtruum, nor, like the gliſſy colours of enamel, to run out of the drawing on the fire. See on this ſubject, Phil. Tranſ. vol. xlix. art. 100 p. 652. art. 101. p. 655. lx. vol. ii. art. 8 p. 40. art. 9. p. 53. Muntz's *Encaustic* Eſſays of count Caylus, in the Hiſt. de l'Acad. Roy. des Inſcript. & Belles Lettres, vol. xxxiv. Handmaid to the Arts, 8vo. vol. i. ch. ix. p. 255. 261. See VASE.

ENCAUSTICE has been ſometimes uſed to denote the art of ENAMELLING.

ENCAUSTUM, *encaustum*, is a name given to powder BLUE.

ENCAUSTUM *ſacrum*, a name given, by many authors, to that fine red colour, uſed for illuminating the capital letters in ſome old manuſcripts. Procopius calls it *kopho*; ſome have called it coccus, and ſome cinnabari. It is ſaid that it was made of the purple colour, extracted from the murex, or purple fiſh, with ſome other additions. It is to be obſerved, that however well this colour, when laid on the parchment, or paper, might reſemble the colours of enamel, yet it was improper to call it *encauſtum*, which ſignifies a *colour burnt in*, as in enamelling: it would have been to have called it ſtramentum, or ink.

ENCEINTE, Fr. from *encelindre*, *to ſurround*, in *Fortification*, the wall or rampart, which ſurrounds a place, ſometimes compoſed of baſtions and curtains either faced or lined with brick, or ſtone, or only made of earth.

The *enceinte* is ſometimes only flanked by round or ſquare towers, which is called a Roman wall.

ENCEPHALI, in *Medicine*, an epithet applied to worms generated in the head; where they occaſion violent pains, inſomuch as, ſometimes, to produce diſtraction.

The word is compounded of the preposition *en*, *in*; and *κεφαλη*, *head*.

There are four kinds of *encephali*; thoſe properly ſo called, which are found in the brain; the *narenarii*, in the noſe; auriculares, in the ears; and the dentales, in the teeth.

The *encephali*, properly ſo called, are rare; but there are certain diſeaſes wherein they ſwarm; and we are told of peſtilential fevers, that have ariſen wholly from them. In one of theſe fevers, the phyſicians, having opened the perſon it had carried off, found a little, ſhort, red worm in the head. Hereupon, they tried various medicines, to find what might deſtroy it; but all in vain, till Malmſey wine, wherein horſe-radiſh had been boiled, was applied; this was no ſooner thrown on the worm, than it died. The ſame remedy was afterwards tried on the ſick, and it recovered them almoſt all. The like worms have alſo been taken out by trepanning, and the patient recovered.

ENCEPHALITES *lapis*, in *Natural Hiſtory*, the name given, by authors, to a ſort of coarſe ſtone, ſuppoſed, in ſome degree, to reſemble the human brain. We have, in the foſſile world, many ſtones, named from the parts of animals, which they have, in reality, been formed from, or owed their original to; and theſe are properly enough called by names denoting the things whoſe forms they wear; but it is a very wrong practice, from ſome ſlight external reſemblances, to give ſuch names to things that never can have been ſuppoſed to be ſo entitled to them. No one can be ſo abſurd as to imagine a human brain can be petrified, though a ſtone may accidentally ſomewhat reſemble its form. The perſon poſſeſſed of ſuch an accidental ſpecimen, ſhould have ranked it among the ſtones to which it properly belonged as a ſtone, whether a flint, a pebble, a nodule, and have named, as an accident only, this form of it; and not have given it a peculiar denomination, as if it were a new ſpecies.

ENCEPHALOS, in *Phyſiology*. See BRAIN.

ENCEPPE', in *Heraldry*, denotes chained, or girt round the middle; as is uſual with monkeys, &c.

ENCERIS, in *Pharmacy*, a word uſed by Galen to ſignify ſmall concretions of wax, which formed themſelves in melted plaiſters, of which wax was one of the ingredients. As they cooled, the wax cooling firſt, and collecting itſelf into little grumes, ſpoiled the conſiſtence and form of the whole compoſition.

ENCHANTERS *Nightſhade*. See NIGHTSHADE.

ENCHANTMENT, of *in*, and *canto*, *I ſing*, denotes certain words and ceremonies uſed by magicians in the practice of their pretended and deluding art; thus called, becauſe the *formulæ* of their *enchantment* were generally compoſed in verſe, and deſigned to be ſung. See CHARM, FASCINATION, MAGIC, SORCERY, and WITCHCRAFT.

ENCHASING, INCHASING, or CHASING, the art of enriching and beautifying gold, ſilver, and other metal-works, by ſome deſign or figures repreſented thereon, in low relievo. See SCULPTURE, *Relievo*, &c.

Chaſing is only practiſed on hollow, thin works; as watch-caſes, cane-heads, tweezer-caſes, or the like. It

is performed by punching or driving out the metal to form the figures from within-side, so as to ſtand out prominent from the plane or ſurface of the metal.

In order to this, they have a great number of fine ſteel blocks, or puncheons, of divers ſizes; and the deſign being drawn on the ſurface of the metal, they apply the inſide upon the heads or tips of theſe blocks, directly under the lines or parts of the figures. Then, with a fine hammer, ſtriking on the metal ſuſtained by the block, the metal yields, and the block makes an indenture or cavity on the inſide; correſpondent to which, there is a prominence on the outſide, which is to ſtand for part of the figure.

Thus the workman proceeds to *chaſe* and finiſh all the parts, by ſucceſſive applications of the block and hammer to the ſeveral parts of the deſign.

And it is ſurpriſing, with what beauty and juſtneſs, by this ſimple piece of mechaniſm, the artiſts in this kind will repreſent foliages, groteſques, animals, hiſtories, &c.

ENCHEIRESIS, *Εγχειρησις*, from *εν*, *in*, and *χειρ*, *a hand*, in *Anatomy*, denotes manual operation; as diſſection.

ENCHELIDES, in *Zoology*, the name of a genus of animalcules, containing the capillary eels, whether of pepper-water, vinegar, &c. See ANIMALCULE and PEPPER, VINEGAR, and EEL.

ENCHELIUS, *Εγχελυς*, in *Ichthyology*, the name given by Ariſtotle, Appian, and all the Greek writers, to the EEL.

ENCHESON, a French word, uſed in our *Law-books* and *Statutes*, ſignifying the occaſion, cauſe, or reaſon, wherefore any thing is done. Stat. 5 Edw. III. cap. 3.

ENCHYMA, of *εγχυω*, *I pour in*, in the *Medical Writings of the Ancients*, a word uſed in ſeveral ſenſes. Some have made it expreſs only an *infuſion*; others have uſed it for what the modern phyſicians call *plethora ad vaſa*, that is, a fulneſs of the veſſels, ſimply conſidered, as relative to themſelves; and others have made it the name of certain forms of liquid medicines, to be injected into the ears, into the thorax, or any other part.

ENCHYMOMA, of *εγχυμα*, from *εγχυω*, in the *Writings of the Antient Phyſicians*, a word uſed to expreſs that ſudden effuſion of blood into the cutaneous veſſels, which ariſes from joy, anger, ſhame, or any other violent emotion of the mind, and is what we uſually call BLUSHING; which, according to Dr. Hunter, is a nervous affection.

ENCHYSOMA, is alſo an afflux of the blood, whereby the external parts are rendered black and blue, as in the ſcurvy, bloody eyes, &c.

ENCHYMONITES, in *Natural Hiſtory*, the name of a kind of ſtone found in Macedonia, and ſome other places, which was alſo called *pæonites* and *pæanites*: it was ſuppoſed to be of great virtue to aſſiſt women in labour. See CRANIDES.

ENCHYSMA, the ſame with CLYSTER or enema.

ENCHYTA, in the *Medical Writings of the Ancients*, a name given to ſuch medicines as were injected into the eyes, or into any part.

Some alſo have uſed the ſame word to expreſs a ſort of funnel, contrived to convey the fumes of medicines to any part of the body.

ENCŒLIA, of *εν*, *in*, and *κοιλια*, *belly*, a word uſed by many of the ancient medical writers, to expreſs the viſcera contained in the abdomen, or lower belly.

ENCLAVE', in *Heraldry*, is where one thing is let into another, particularly where the jointure is ſquare.

ENCLITICA, of *κλινω*, *I incline*, in the *Greek and Latin Grammar*, certain particles, united ſo cloſely to the preceding word, that they only ſeem to form one word therewith; and the word which ſuſtains them does generally likewiſe bear the accent that governs them, eſpecially when the *enclitic* is a monoſyllable; as in *dominuſque*, *nunquid*, &c.

There are three *enclitic* particles in the Latin, viz. *que*, *ne*, and *ve*; but in the Greek may, as τε, μι, μοι, με, σε, σου, σε, τις, του, των, τι, τοι, τινος, τινι, τινα, and others.

ENCONDRUS, of *εν*, *in*, and *κονδρος*, *grain*, in the *Old Greek Writers*, a word uſed to expreſs any thing made up of a great number of ſmall pieces, or flakes, or ſmall grains of any thing. The manna of the ancients was not in large flakes, as we have it at preſent, but it was formed of a vaſt number of ſmall granules, and was therefore called by Dioſcorides, and ſome others of the Greeks, by this name. The word manna alſo ſignified with them the ſame thing; and they not only expreſſed the ſubſtance by it which we at preſent call ſo, but any other things that was in ſmall flakes, or pieces, was called manna. Thus the manna thuris, ſo much talked of among the old Greeks, was only a collection of thoſe pieces which flew off from frankincenſe in the breaking. See MANNA *Thuris*.

ENCOPE, of *ο* and *κοπτω*, *I cut*, in *Surgery*, an inciſion of any part; as in a gangrene, &c.

ENCOUNTERS, in *Military Language*, a combat between two perſons; and the term is alſo more generally applied to attacks or battles between ſmall or large armies.

ENCRANIUM, in *Anatomy*, the ſame with CEREBELLUM.

ENCRASICOLUS, the anchovy, a ſmall ſea-fiſh, one of the harengiform kind, but wanting the row of ſerrated ſcales on the belly. They are caught in vaſt plenty in the Mediterranean, the Engliſh, and many other ſeas, and are well known in pickle in moſt nations of Europe. See ANCHOVY.

ENCRATITÆ, formed from *εγκρατης*, *continent*, a ſect of ancient heretics, thus called from their making profeſſion of continence, and abſolutely rejecting all uſe of marriage.

The founder of this ſect was Tatian, a diſciple of Juſtin, and one of the moſt learned perſons of all antiquity. After the death of that martyr, he made a ſeparation from the church, and ſoon had his followers; who, beſide the dogma juſt mentioned, borrowed a great many things from Saturninus and Marcion; beſide ſeveral errors, which they adhered to in common with the Gnoſtics and Valentinians.

They abſtained from eating any thing that had life, and denied that Adam was ſaved. They looked on ſuch as drank wine to be great ſinners; and for this reaſon only made uſe of water in celebrating the Euchariſt, as holding, that wine came from the devil. To countenance this tenet, they produced paſſages out of ſcripture, where mention is made of what befel Noah and Lot, when they were drunk.

They only admitted ſuch of the books of the Old Teſtament as they thought good; but in lieu thereof, they owned ſeveral ſpurious and apocryphal writings for canonical and divine. Such were the Acts of St. Andrew, John, and Thomas.

ENCRAULOS, in *Ichthyology*, the name given by Ariſtotle and many other of the ancient Greeks, to the fiſh which we call the anchovy. Authors deſcribe this under the diſtinct name of encraſicolus; but Artedi proves it to be a ſpecies of the ſame genus with the herring, and calls it the clupea with the upper jaw longer than the under. This name carries a diſtinction with it that cannot be miſtaken.

ENCRINOS, in *Natural Hiſtory*, a name given by authors to a ſpecies of aſteropodium, or that plated or imbricated body which makes the baſe or foot of the aſteria. This is compoſed of a number of ſmall plates, convex on one ſide, and concave on the other; and when found in fair pieces, is ſaid very exactly to reſemble a part of a ray of the magellanic ſtar. See ASTEROPODIUM.

ENCRIS, in the *Medical Writings of the Ancients*, ſignifies a ſort of cake made of fine flour, mixed with oil, and ſweetened with honey.

ENCROACHMENT, or ACCROACHMENT. See INCROACHMENT, and ACCROACHING.

ENCUMONIS, ſee ENCHYMONITES.

ENCURECK, in *Natural Hiſtory*, a venomous inſect, found in Perſia, and ſuppoſed by ſome to be a kind of tarantula. It neither ſtings nor bites, but lets fall its venom like a drop of water, which cauſes inſufferable pain in the part for a time; and afterwards ſo profound a ſleep, that we are told, nothing can raiſe the patient from it but cruſhing one of thoſe creatures on the part affected. It is nevertheleſs ſaid, that the ſheep eat theſe inſects without damage. Olearius, ap. Boyle, Works abr. vol. i. p. 57. Ibid. p. 38.

ENCYCLOPÆDIA, the circle or chain of arts and ſciences.

The word is compounded of the prepoſition *εν*, *in*, κυκλος, *circle*, and παιδεια, *eſtrine*, *doctrina*, *diſciplina*, *learning*; the root being παις, *child*, *infant*.

The Greeks uſed the term for the knowledge of the ſeven liberal arts; and the perfection of all the ſciences. *Orbis ille doctrinæ quem Græci* ἐγκυκλιοπαιδειαν *vocant*, ſays Quintilian. It is ſometimes alſo written, κυκλοπαιδεια, *cyclopædia*. Vitruvius, in the preface to his ſixth book, calls it, *encyclios diſciplinas*. See CYCLOPÆDIA.

END *for* END, in the *Sea Language*, when a rope runs all out of the block, ſo that it is unreeved, they ſay it is run out *end for end*.

ENDECAGON, or HENDECAGON, in *Geometry*. See HENDECAGON.

ENDECASYLLABUS, or HENDECASYLLABUS. See HENDECASYLLABUM.

ENDECERES, of *ενδεκα*, *eleven*, in the *Naval Architecture of the Ancients*, a word uſed to expreſs a galley which had eleven ſeries or tires of rowers. Thoſe with two or three tires were very much in uſe among the ancients, and from thoſe to ſuch as had five or ſix tires. Thoſe of nine tires were ſometimes uſed, but it was very ſeldom; and thoſe of eleven, fifteen, and ſo on, were rather for ſtate than ſervice. We read of them carried ſo high as to contain twenty, thirty, and forty rows of oars. One of

this largeſt ſort was built for Philopater, which required four thouſand men.

ENDEIXIS, of ἐνδείκνυμι, *I indicate*, in *Medicine*, an indication of diſeaſes, whereby is ſhewn what is to be done; as for example, a *plethora*, or too great fulneſs of blood, indicates the opening of a vein. Blancard, in voc. See DISEASE.

ENDEIXIS, Endeix, in *Antiquity*, an action brought againſt ſuch as affected any places or things, of which they were incapable by law. Potter Archæol. Græc. lib. i. cap. 23. tom. i. p. 125.

ENDEMIC *diſeaſe*, of ἐν and δῆμος, *people*, that which at ſeaſons many people together in the ſame country, as proceeding from ſome cauſe peculiar to the country where it reigns. See DISEASE.

ENDENTED, DENTED, or INDENTED, in *Heraldry*. See INDENTED.

ENDENTÉE, is alſo applied to a feſs or pile, and other triangular pieces, when divided alternately between two different colours. Compt. or ordered with or ſable and argent.

ENDESIS, from ἐν and δέω, *I bind*, a word uſed by ſurgeons to expreſs that part of the foot where the bones of the tibia end, and which is connected by ligaments to the ankle.

ENDEW, in *Falconry*, is ſaid of a hawk that digeſts her meat ſo well, that ſhe not only diſcharges her gorge of it, but even cleanſes her pannel.

ENDICA, a word uſed by the alchemiſts for the faeces which ſubſide to the bottom of the veſſel in infuſions; to ſome of which they attribute great virtues.

ENDITEMENT, or INDICTMENT, in *Common Law*. See INDICTMENT.

ENDIVE, or SUCCORY, *endivium*, in *Botany*, a genus of the *ſyngeneſia polygamia æqualis* claſs. Its characters are theſe: the flower hath a common ſcaly empalement, which at firſt is cylindrical, but it afterward expanded; the florets are narrow, four-ſhaped, and equal. The flower is compoſed of many hermaphrodite florets with one petal, which is tongue-ſhaped, and cut into five ſegments. Theſe have five ſhort hairy ſtamina in the germen is ſituate under the petal, which afterwards becomes a ſingle ſeed, incloſed with a down, and ſhut up in the empalement. Linnæus enumerates three and Miller four ſpecies.

The curled *endive* is now much cultivated in the Engliſh gardens, being one of the principal ingredients in the ſallads of autumn and winter; for which purpoſe it is continued as long as the ſeaſon will permit. The firſt time for ſowing theſe ſeeds is in June; for thoſe which are ſown earlier in the year, generally run up to ſeed before they are arrived to a proper ſize for blanching.

Thoſe plants which were firſt tranſplanted will be fit to blanch by the end of Auguſt at fartheſt; and if they are properly managed, in three weeks or a month they will be ſufficiently blanched for uſe; which will be as ſoon as theſe ſallads are commonly required; for during the continuance of good cos lettuce, few perſons care for *endive*.

As the quantity of roots required for a middling family is not very great, ſo there ſhould not be too many plants tied up to blanch at the ſame time. The manner of tying them is, firſt gather all the inner leaves of the plant in regular order into one hand; and then take up all thoſe that are found of the outſide ones, pulling off the decayed ones which lie near the ground, obſerving to place the outſide leaves near the middle ones, as near as poſſible in their natural order, ſo as not to croſs each other. Having thus got the whole plant up in your hand, tie it up with baſs or twigs, at about two inches below the top, very cloſe. About a week after, the plants ſhould be gone over again to have another tie round the middle, to prevent the heart leaves from burſting out on one ſide, which they are ſubject to do, as the plants grow, if not prevented.

After October, when the nights begin to be froſty, thoſe plants which are fat above ground will be liable to be prejudiced thereby, eſpecially if not covered up at ſuch times: the beſt method, therefore, for the late crops, is to take up the plants in a very dry day, and with a large flat pointed dibble plant them into the ſides of trenches of earth, which ſhould be laid very upright, ſideways towards the ſun, with the tops of the plants out of the ground, ſo that the haſty rains may run off, and be kept dry and ſecured from froſts. The plants thus treated, will be blanched fit for uſe in about three weeks or a month's time; after which they will not keep good long. The wild *endive*, of which there are ſome varieties in the colour of the flowers, is ſeldom propagated in gardens, it growing wild in unfrequented lanes and dunghills, in divers parts of England, where the herb-women gather it, and ſupply the markets for medicinal uſe. Miller.

The common *ſuccory* ſtands recommended by moſt of the medical writers, as one of the beſt known aperients and detergents; it is preſcribed in all diſeaſes of the liver, and is a powerful diuretic. Schroder tells us, that it has alſo great virtues attributed to it againſt hæmorrhages; but it is not much regarded at preſent in theſe caſes.

ENDIVIA *marina*, *the ſea-endive*, in *Natural Hiſtory*, the name of a ſpecies of ſea-plant, deſcribed by count Marſigli. There are two ſpecies of it, the one having broad and jagged leaves, reſembling thoſe of the vine, the other much narrower. This laſt kind grows on ſhoals, ſtones, pieces of wood, or any other ſubſtances, accidentally found at the bottom of the ſea. It seldom grows in very deep water, and rather beſt in places where the ſea is calm and open. Its is of a dusky greenish colour, variegated in ſome places with yellow. It exactly reſembles the ſhape of the *endive* cultivated in our gardens, and its leaves are cut and fringed in the ſame manner; but they are of ſo tender a ſubſtance, that a ſlight touch deſtroys them; they are indeed tenderer and more delicate than thoſe of any other known plant, either of the ſea or land. When this plant is examined by the microſcope, its ſurface is found to be compoſed of a great number of eminences and cavities, or little lodges between and among them; and when the leaves are put tranſparently, there are ſeen a great number of glandules in them. Marſigli. Hiſt. de la Mer, p. 72. See COralLINA.

ENDLESS *ſcrew*, and *ſpiral*, ſee the ſubſtantives.

ENDORSE, in *Heraldry*, an ordinary, containing the eighth part of a pale.

This, Leighton, is never uſed but when a pale is between two ſuch; though others hold, that an *endorſe* may be borne between birds, fiſhes, beaſts, &c. Sir J. Ferne adds, that it ſhews the ſame coat has been ſometimes two coats, and afterwards conjoined within one eſcutcheon, for ſome myſtery of arms. He bears azure an *endorſe* argent. Edw. II. *Herald. fig.* 18.

ENDORSED, ENDORSE, in *Heraldry*, is where things are borne back to back.

ENDORSEMENT, of *in* and *dorſum*, *back*, is particularly uſed in *Commerce*, for a writing on the back of a bill of exchange by the proprietor or bearer, either thereby to transfer it to ſome other, or to render it payable to the order of ſome other, or elſe to ſerve for an acquittance or receipt. See EXCHANGE.

The *endorſement* is only the name of the proprietor, or *endorſer*. Note, when the *endorſement* of a bill of exchange is to render it payable to another, it is called an *order*.

To an order it is neceſſary the *endorſement* be dated, and contain the name of him who paid the value thereof; in which caſe, the bill belongs to the perſon with whoſe name the order is filled, without any other tranſaction; without theſe conditions, the bill is judged to belong to the perſon who *endorſed* it. The bearer of a bill of exchange protected has a remedy againſt the *endorſers* for the payment of the re-change of the places where the bill was negociated by their order. In caſe a bill or note is refuſed to be paid, &c. the bearer has a remedy againſt any one of the *endorſers*, where there are ſeveral. See BILL.

ENDORSING, or INDORSING, in *Law*, implies the writing on the backſide of a deed, inſtrument, &c. ſomething relating to the matters contained therein.

ENDOSIS, Endosis, of ἐν and δόσις, *I give*, in the *Medical Writings of the Ancients*, a word uſed to expreſs a remiſſion of any kind, as when a tumor, inflammation, or hardneſs of any part, becomes leſs violent; and when the patient becomes eaſier, after the exacerbations in fevers of the continual kind, and after fits of the intermittent.

ENDOWMENT, or INDOWMENT, the giving or aſſigning of a dower to a woman. See DOWER.

The word is alſo uſed figuratively, for the ſetting forth or ſevering of a ſufficient portion for a vicar, towards his perpetual maintenance, when the benefice is appropriated; whence ſuch a vicarage is called a *vicarage endowed*.

ENDYMATIA, in *Antiquity*, a kind of dance uſed among the Greeks, performed in Arcadia, to the ſound of certain airs compoſed for the flute.

ENELIAXIS, Enelixis, or rather *Enyaliaxis*, Enyalixis, in *Antiquity*, a feſtival in honour of Enyalius, whom ſome will have to be the ſame with Mars, others only one of his miniſters. Potter. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

ENEMA, of ἐνίημι, *I put in*, in *Medicine*, denotes a *cluſter*. See CLYSTER.

ENEMY. See ALIEN.

ENFOREMA, of ἐπείρω, *I lift up*, is uſed by ancient medical writers for thoſe parts of the urine which float about in the middle reſembling a cloud, formed, according

rording to Boerhaave, principally of muriatic salt. Comm. Inſtit. § 382.

ENEOS, *of* ἐν and νοῦς, *I cry*, a word uſed by the ancient writers in *Medicine* for a perſon born deaf, or unable to perform the common offices of life, for want of any of the principal organs.

ENERGETICAL *bodies or particles*, are ſuch, as are eminently active, and which produce manifeſt operations of various natures, according to the various circumſtances and motions of ſuch bodies or particles.

ENERGICI, an appellation given to certain diſciples of Calvin and Melanchthon, of the ſixteenth century, becauſe they held the Euchariſt was the energy and virtue of Jeſus Chriſt; not his real body, nor a repreſentation thereof.

ENERGUMENUS, Ἐνεργούμενος, a term ſometimes uſed by divines and ſchoolmen, to ſignify a perſon poſſeſſed with a devil, or an evil ſpirit.

The word is formed from the Greek, ἐνεργεῖσθαι, *to be agitated, worked*, of ἐν, and ἔργον, *opus*.

Though Papias ſays, the *Energumeni* were ſuch as counterfeited the actions of the devil, performing things which ſeemed ſupernatural. The council of Orange declares, or deprives the *Energumens* of the functions of the prieſthood. See DEMONIAC.

ENERGY, an uncommon force or ſtrength in a diſcourſe, a ſentence, or a word. See EMPHASIS.

The word is Greek, ἐνεργεία, formed of the prepoſition ἐν and ἔργον, *work, labour*.

ENERVATING, the act of deſtroying the force, uſe, or office, of the nerves, either by cutting them, by weakening them with debauchery, or by ſome other violence.

Exceſs of wine, and other ſtrong, hot, ſpirituous liquors, *enervate* or weaken the nerves. When they would render a horſe reſtleſs, they *enervate* him, or cut his nerves.

ENERVATING, is particularly uſed in the *Manege*, for the cutting two tendons on the ſide of a horſe's head, under the eye, which meet on the tip of the noſe; they thus *enervate* horſes, to make their heads ſtrait and learn.

The word is alſo uſed figuratively. It is no ſmall artifice in diſputing, to be able to *enervate* and extenuate the allegations of one's antagoniſt. This author has a weak, *enervate* ſtyle. See NERVE.

ENERVATION, a term in the *Ancient Anatomy*, applied to the tendons of the veſti, or ſtraight muſcles of the abdomen.

The fibres of the veſti of the abdomen do not go from one extreme of the muſcles in the other, but are interſected by ſeveral nervous places, called by the ancients *enervations*, though they be real tendons.

Their number is not alike in all; ſome having three, others four, &c.

ENFANS *perdus*, a French phraſe, uſed in *War*, to ſignify the ſoldiers who march at the head of a body of forces appointed to ſuſtain them, in order to begin an attack, make an aſſault, or force a poſt.

The word literally imports *loſt children*, on account of the imminent danger they are expoſed to.

In Engliſh, they are called the *forlorn*, or *forlorn hope*.

At preſent, the grenadiers uſually begin ſuch attacks.

ENFILADE, a French term, ſometimes uſed in Engliſh, ſignifying a ſeries or continuation of ſeveral things, diſpoſed, as it were, in the ſame thread or line; as an *enfilade* of rooms, of doors, of buildings, &c.

The word is formed of the French verb, *enfiler*, *to string a thing*, which is compounded of *en*, *in*, and *fil*, of *filum*, *thread*; q. d. a thread or ſtring of any things.

ENFILADE, in *War*, is applied to thoſe TRENCHES, and other lines, which are ranged in a right line, and ſo may be ſcoured or ſwept by the cannon lengthways, or in the direction of the line, and rendered almoſt defenceleſs.

Care muſt be taken that the lines be not *enfiled*, or *enfiladed*; on the contrary, the covert line muſt be *enfiladed*, that the enemy may be driven out of it. The laſt boyau, or gut of the trenches, is ſubject to be *enfiladed*, that is, to be ſcoured according to its length.

A *battery d'enfilade*, is that where the cannon ſweep a right line.

A *poſt*, or command *d'enfilade*, is a height from which one may ſweep a whole line at once.

ENFRANCHISEMENT, the incorporating any man into a ſociety or body politic. See FREEDOM and FRANCHISE.

Thus, he that by charter is made denizen of England, is ſaid to be *enfranchiſed*. The like is underſtood of a perſon made a citizen of London, or other city or corporate town; becauſe he is thereby made partaker of the liberties appertaining to the corporation whereof he is *enfranchiſed*.

ENGAGEMENT, in a *Naval Senſe*, denotes a particular or general battle at ſea, or an action of hoſtility between ſingle ſhips, or detachments, or ſquadrons of men of war: the whole œconomy of which may be arranged under the heads of preparation, action, and repair. The preparation is begun by *iſſuing* the order to clear the ſhip for action, which is repeated by the boatſwain and his mates at all the hatchways. The hammocks are firſt removed; every ſailor ſtowing his own bedding properly and firmly cording it with a lathing, or line provided for that purpoſe: as each ſide of the quarter-deck and poop is furniſhed with a double net-work, ſupported by iron cranes fixed immediately above the gunnel or top of the ſhip's ſide; the hammocks thus corded, are firmly ſtowed by the quarter-maſter between the two parts of the netting, ſo as to form an excellent barrier or ſort of parapet, to prevent the execution of ſmall ſhot on the quarter-deck: the tops, waiſts, and fore-caſtle, are fenced in the ſame manner. At the ſame time the boatſwain and his mates are employed in ſecuring the ſail-yards, to prevent them from tumbling down when the ſhip is cannonaded, whereby it might be diſabled. The yards are ſecured by ſtrong chains or ropes, beſides thoſe by which they are uſually ſuſpended. The boatſwain alſo provides the neceſſary materials for repairing the rigging; and the carpenter and his crew prepare ſhot plugs and mauls to cloſe up any breach that may be made near the ſurface of the water, and provide the iron-works neceſſary to reſiſt the chain-ſhot. The gunner with his mates and quarter-gunners, examine the cannon of the different batteries, and provide proper charges, &c. The maſter and his mates attend to the number and trimming of the ſails, &c. The lieutenants viſit the different decks, taking care that all incumbrances are removed, and giving inſtructions to the other officers, that every thing may be ready for the expected *engagement* at a moment's warning. When the hoſtile ſhips have approached each other to a competent diſtance, the drums beat to arms: the boatſwain and his mates pipe *all hands to quarters* at every hatch-way. The perſons appointed to manage the great guns immediately repair to their reſpective ſtations; crows, hand-ſpikes, rammers, ſponges, powder-horns, matches, and tram-tackles are placed in order by the ſide of every cannon: the hatches are laid to prevent any one from eſcaping into the lower apartments. The marines are drawn up in rank and file, on the quarter-deck, poop, and fore-caſtle. The lidings of the great guns are let looſe, and the tompions withdrawn: the whole artillery, above and below, is run out at the ports, and levelled to the point-blank range ready for firing. When the neceſſary preparations are finiſhed, the commencement of the action is determined by the mutual diſtance and ſituation of the adverſe ſhips, or by the ſignal from the commander in chief of the fleet or ſquadron. The cannon being levelled in parallel rows, projecting from the ſhip's ſide, the moſt uſual order of battle is evidently to range the ſhips abreaſt of each other, eſpecially if the *engagement* is general. The moſt convenient diſtance is probably within the point-blank range of a muſket, ſo that all the artillery may do effectual execution. The combat uſually begins by a vigorous commonade, accompanied with the united efforts of all the ſwivel guns and ſmall arms. Inſtead of firing platoons, or volleys of cannon at once, the general rule on theſe occaſions throughout the ſhip is to load, fire, and ſponge the guns with all poſſible expedition, yet without confuſion or precipitation. The captain of each gun is enjoined to fire only when the piece is properly directed to its object. The officers who command the different batteries traverſe the deck, to ſee that the battle is proſecuted with vigour, and to animate the men in their duty. The midſhipmen ſecond theſe injunctions, and give aſſiſtance where it is required at the guns committed to their charge. The gunner takes care that the artillery is ſupplied with powder, and that the cartridges are conveyed along the decks in covered boxes. The ſhip that is defeated acknowledges the victory by ſtriking the colours, and is immediately taken poſſeſſion of by the conqueror, who ſecures her officers and crew as priſoners in his own ſhip, and involls two principal officers with the command of the priſe till a captain is appointed by the commander in chief. When the *engagement* is concluded, they begin the repair. The cannon are ſecured by their breachings and tackles; the ſails that have been rendered unſervicеable, are unbent, and the wounded maſts and yards ſtruck upon the deck, and fitted or replaced by others. The ſtanding rigging is knotted, and the running rigging ſpliced as neceſſity is neceſſary. Proper ſails are bent in the room of thoſe that are become uſeleſs. The carpenter and his crew repair breaches in the ſhip's hull by ſhoring pieces of plank, and sheet-lead. The gunner and his aſſiſtants repleniſh the allotted number of charged cartridges, and refit the damaged furniture of the cannon.

When two fleets or ſquadrons are preparing for *engagement*, it will be the endeavour of the admiral or commander in chief to come to action in ſuch a manner as to facilitate the execution of the admiral's orders, the whole

whole fleet is ranged into three squadrons; each of which is classed into three divisions, under the command of different officers. Before the action begins, the adverse fleets are commonly drawn up in two lines parallel to each other, and close-hauled. When the admiral displays the signal for the line of battle, the several divisions separate from the colours in which they were disposed according to the usual order of sailing, and every ship crowds into its station in the wake of the next a-head, at the distance generally of about fifty fathom; which distance is regularly observed from the van to the rear: though the admiral may sometimes find it necessary to contract or extend his line, according to the length of that of his adversary; always taking care that his own line be secured from being doubled, which might throw his van and rear into confusion. When the adverse fleets approach each other, the courses are commonly hauled up in the brails, and the top-gallant sails and stay-sails furled: the frigates, tenders, and fire-ships, being hauled upon the wind, lie at some distance behind the line of battle; and transports and store-ships lie beyond these, at a still greater distance from the scene of action; and if the number of ships allows it, a body of reserve from the different squadrons is selected to cover the fire-ships, &c. and stationed opposite to the weakest parts of the line, so that they may readily fall into the line in case of necessity. Each ship forming the line should keep close to its station during the *engagement*; the assault of boarding being seldom permitted unless in single action: because the regularity of a close line constitutes the principal force of the fleet; and the skill of the admiral is greatly concerned in keeping his line, notwithstanding unequal attacks and damage, as complete as possible. If he proves victorious, he should prosecute his victory as much as possible, by seizing, burning, or destroying the enemies ships. If he is defeated and reduced to the necessity of retreating, he may judge it expedient, for greater security, to range his fleet into the form of a half-moon, placing himself in the centre. The enemy's ships that attempt to fall upon his rear will thus be exposed to the fire of the admiral and his seconds, and the escape of his own ships will be facilitated whilst the pursuit of his adversary is retarded. Upon the whole, the real force or superiority of a fleet consists less in the number of vessels and the vivacity of the action, than in good order, dexterity in working the ships, presence of mind and skilful conduct in the admiral and captains. Falconer's Marine Dict. Art. ENGAGEMENT. See BATTLE, LINE *of battle*, and SIGNAL.

ENGAGEMENT, in *English History*, was the obligation imposed by Oliver Cromwell required to be signed by every member of the First Parliament in 1654, assembled by his authority, after he was declared Protector, viz. I *A. B.* do hereby freely promise and engage myself to be true and faithful to the Lord Protector, and to the commonwealth of England, Scotland, and Ireland, and shall not (according to the tenure of the indenture whereby I am returned to serve in this present parliament) propose or give any consent to alter the government, as it is settled in one single person and a parliament. Many, who refused to sign this *engagement*, were excluded from the house.

ENGAMOS, in *Natural History*, the name given by the people of some parts of Guinea to a root very common there, and much resembling our larger sort of turneps, but not so sweet or juicy. They commonly boil these with their partridge, in the same kettle with their meat. The latter of these roots, which is considerably different from our potatoe, gives a fine flavour to the whole, and makes the broth and meat taste as if rose-water were added to it. The *engamos* also partakes of the flavour, and in this case becomes very agreeable. Phil. Trans. N° 198.

ENGASTRIMANTES, *Εγγαστριμαντες*, in *Antiquity*, called also ENGASTRIMYTHI, *Εγγαστριμυθοι*, a denomination given to such diviners as were possessed with demons, which either lodged or spoke within their bodies. Potter. Archæol. Græc. lib. ii. cap. 12. tom. i. p. 301.

ENGASTRIMYTHUS, *Εγγαστριμυθος*, or ENGASTRIMANDER, a person who speaks from, or with the belly, without opening his mouth; or, if open, without stirring the lips. Thus called by the Greeks, from ιν, *within*, γαστηρ, *belly*, and μυθος, *speech*; and by the Latins, *ventriloqui*, *quasi ex ventre loqueres*.

The ancient philosophers, &c. are divided on the subject of the *engastrimythi*. Hippocrates mentions it as a disease. Others will have it a kind of divination, and ascribe the origin and first discipline thereof, to one Eurycles, whom nobody knows any thing of. Others attribute it to the operation or possession of an evil spirit; and others, to art and mechanism.

The most eminent *engastrimythi* were the Pythians or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips.

St. Chrysostom and Oecumenius make express mention of a sort of divine men, called by the Greeks *engastrimanders*, whose prophetic bellies pronounced oracles.

M. Schottus, library-keeper to the king of Prussia, in a Dissertation on the Apotheosis of Homer, maintained that the *engastrimythi* of the ancients were only poets; who, when the priestess could not speak in verse, supplied the defect, by explaining or delivering in verse what Apollo dictated in the cavity of the bason, placed on the sacred tripod.

Leo Allatius has an express treatise on the *engastrimythi*. See VENTRILOQUISTS.

ENGENDERING, or INGENERING, the act of begetting or producing the kind, by way of generation.

The term is likewise applied to other productions of nature: thus, meteors are said to be *engendered* in the middle region of the air. Crude fruits *engender* worms. The ancients believed, that insects were *engendered* of putrefaction.

ENGINE, in *Mechanics*, a compound machine, consisting of several simple ones, as wheels, screws, levers, or the like, combined together, in order to lift, pull, or sustain a weight, or produce some other considerable effect, so as to save either time or force.

The word is formed of the French, *engine*; of the Latin, *ingenium*, *wit*; because of the ingenuity required in the contrivance of *engines*, to augment the effect of moving powers.

The kinds of *engines* are infinite; some for war, as the BALISTA, CATAPULTA, SCORPIO, ARIES, &c. others for the arts of peace, as MILLS, CRANES, PRESSES, CLOCKS, WATCHES; *engines* to drive piles, to raise water, WHEEL and WATER-*works*; to extinguish fire, see FIRE-*engine*, &c. See HYDROCANISTERIUM. See STEAM-*engine*, &c. See also INSTRUMENT.

ENGINEER, or INGINEER, in its general sense, is applied to a contriver or maker of any kind of useful engines or machines.

In its more proper sense, it denotes an officer in an army or fortified place, whose business is to contrive and inspect attacks, defences, works, &c.

An *engineer* should be an able and expert mathematician, particularly versed in military architecture and gunnery; being often sent to view and examine the places intended to be attacked; to choose out, and shew the general the weakest place; to draw the trenches, assign the places of arms, galleries, lodgments on the counterscarp and half-moons; conduct the works, saps, mines, &c. and appoint the workmen in their nightly tasks; he is also to make the lines of contravallation; with the redoubts, &c.

Under the establishment of the office of his majesty's ordinance, the corps of *engineers* consists of one colonel in chief, two directors or lieutenant colonels, four sub-directors or majors, twelve *engineers* in ordinary or captains, twelve *engineers* extraordinary or captains, seven sub-*engineers* or first lieutenants, twenty-four practitioner-*engineers* or second-lieutenants, and two *fire-engineers* on the Irish establishment. See ORDNANCE.

ENGISOMA, *Εγγισωμα*, from ιν, *in*, σωμα, a species of fracture of the skull, wherein one of the extremities of the fractured bone is thrust inwards upon the dura mater, and the other extremity raised outwards. See TREPANNING.

ENGLECERIE, ENGLECHERIE, or ENGLESCHYRE, a term of great import among our ancestors, though now obsolete; properly signifying the quality of an Englishman.

If a man were privately slain, or murdered, he was anciently accounted FRANCIGENA (which comprehended every alien, especially the Dane) till *englecerie* was proved, i. e. till it was made to appear that he was an Englishman. Bracton, lib. iii.

The origin of the custom anciently subsisting among the Goths in Sweden and Denmark, was thus: king Canutus, having conquered England, at the request of his nobles, sent back his army into Denmark, only reserving a guard of Danes for his person; and made a law, that if any Englishman killed a Dane, he should be tried for the murder, or, if he escaped, the village where the man was slain should be charged to pay forty-six marks into the exchequer. After this law, which was continued by William the Conqueror, for the like security to his own Normans, whenever a murder was committed, it was necessary to prove the party slain an Englishman, that the penalty of forty-six marks might not be charged on the village. This practice was abolished by statute 14 Edw. III. cap. 4.

ENGLISH, in a general sense, something that relates to the country or people of England.

We lay, the *English* crown, *English* coppers, *English* names, *English* money, *English* measures, *English* weights, &c.

The fretting Gelraft is called by foreigners, *from Aquitaine, the English ague*. Dr. Cheyne calls the vapours the *English malady*. See SPLEEN-MELICHOLY.

ENGLISH *Dogs*. See DOG.

ENGLISH, or the *English Tongue*, the language spoken by the people of England, and with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The *English* is of Gothic, or Teutonic extraction: this was the root on which several other dialects have been grafted, particularly the Latin and French. See PROVINCE, &c.

The Saxon anciently spoken in our island was the British, or Welsh, which was common to the Britons and Gauls; and which still subsists, in manner as entire, in the principality of Wales, the islands and Highlands of Scotland, part of Ireland, and some provinces of France, particularly Bretagne, and very lately subsisted in the county of Cornwall. See CORNISH *language*. According to some, the ancient language of this island was the Celtic or Gaelic, of which the Irish, Welsh, and Erse are no other than different dialects. Bloft's Lecton Rhetoric, p. 178.

As the Roman empire, extending itself towards the western parts of Europe, under Julius Cæsar, Claudius, and Domitian, came to take in Gaul and Britain, the Roman tongue became propagated therewith; all the edicts, &c. relating to the public affairs, being designedly wrote in that language.

The Latin, however, it is certain, never got to much ground, or prevailed so far in England, as in Lombardy, Spain, and the Gauls; partly on account of its great distance from Rome, and the small resort of Romans hither; and partly, because the entire reduction of the kingdom was not effected till so late as the reign of Claudius, when the empire was on the declining hand, and the new province was forced to be soon deserted by its conquerors, called to defend their territories nearer home.

Britain, thus left naked, became an easy prey to the *Angli*, or Anglo-Saxons, a flouling nation, from Jutland and Norway, who took an easy possession thereof about the year 450, much about the time that the Franks, another German nation, entered Gaul. The Gauls and Franks, it seems, at length came to terms; found means to unite into one nation; and thus, the ancient Gaulish, with its mixture of Latin, continued the prevailing tongue, only further intermixed with the Francic or lingua Franca of their new inmates: but the Britons were more constant, and determined absolutely to refuse any such coalition: they had embraced Christianity, Augustine being sent from Rome to convert them about the year 570, and their conditions were, however, rather that admit of such an union, therefore, they chose to be shut up, with their language, in the mountainous parts of Cambria or Wales.

The *English* Saxons, thus left absolute lords, changed every thing; their own language was now fully established; and the very name of the country was henceforth to be Anglo-Saxon. The new language remained in good measure, pure and unmixed, till the Norman invasions: the attempts of the Danes, and the neighbourhood of the Britons, indeed, wrought some leffer innovations therein; but, in the main, is preserved intire; for, as to the Danes, their language was not much different from the other. Edward the Confessor, however, who had lived long in France, might possibly bring in a little mixture of the dialect of that country.

But William I. and his Normans, having got possession of England, an alteration was soon attempted; the conquest was not complete, unless the Conquerer's language, the French or Franco-Gallic were introduced: and accordingly, all his acts, diplomas, edicts, pleadings, and other judicial matters, were written, &c. in that tongue.

But his attempts proved unsuccessful; the number of Normans he brought over being very small in comparison of the *English*, with whom they were incorporated, they lost or forgot their own language, sooner than they could make any change in the *English*. This, however, did not hinder, but, by the endeavours of the Conquerer, abundance of French words, though many of them of Latin original, crept into the *English*; and many *English* words, by degrees, grew out of use.

Hence, as to the origin and etymology of many of our words, Dr. Wallis lays it down, that such words of German original as we have in common with the French, are to be reckoned as our own, rather than as words borrowed from them; and that the old Gaulish words, common to the French, and the Welsh, which are found in our language, have been likewise taken from the Welsh, rather than from the French. Hence, also, the same author accounts why the names of the divers sorts of cattle are Saxon; as ox, cow, calf, sheep, hog, boar, deer, &c. and yet that their flesh when prepared for food, is French; as beef, veal, mutton, pork, bacon, venison, &c. the Norman nobility, not contenting themselves with pasture, parks, and the like places, where such creatures are fed and kept, to much as with pastures, pleasures, walks, and entertainments, where the food was either prepared, sold, or eaten.

Under Henry II. Dr. Swift observes, the French made a still greater progress, because of the large territories he possessed on that continent, both from his father and his wife, which occasioned frequent journies thither, with numerous retinues, &c. And for some centuries after, there was a constant intercourse between France and England, by the dominions we possessed there, and the conquests we made; so that the language, two or three hundred years ago, seems to have had much more French than it at present.

Besides this abundance from the conquerors, the language in process of time underwent several others; and at length came to have numerous words and phrases of foreign dialects ingrafted into it, in lieu of the ancient Saxon; particularly, by means of negociations and commerce with other nations; by the marriages of royal families; by the affectation of many writers, in most ages, who are fond of coining new words, and altering the usual forms of speech, for the greater delicacy; and, by the necessity of framing or borrowing new words, according as new things and inventions turn up: and by such means was the old Anglo-Saxon converted into the present *English* tongue.

Having traced the rise and progress of our language historically, we think it may be no incurious amusement to represent by actual examples the several successive changes and stages it has passed through, to arrive at its present perfection: in order to which, we shall make use of the collections of the ingenious Mr. Green wood.

From the Saxon invasion, we have no memorial extant of the language for 250 years: the oldest Saxon writing in being is a gloss on the Evangelists, written in the year 700, by Eadfride, bishop of Holy Island; in which the three first articles of the Lord's Prayer run thus:

" Uren Fader thic arth in heofnas, tu gehalgod
" thin noma, to cymeth thin ric. Sie thin willa
" fue is heofnas, and in corthe," &c.

Two hundred years after, in the year 900, the same was rendered thus:

" Thin ure Fader the eart on heofenum, si thin
" nama gehalgod; cume thin rice. Si thin willa on
" corthan swa, swa on heofenum."

In the following age it was turned thus in the Saxon Homilies, said to be translated by king Alfred:

" Fader ure thin the eath on heofenum, si thin
" nama gehalged, to be come thin rice, gewurthe
" thin willa on corthan lufa, swa on heofnum," &c.

About the year 1160, under Henry II. near which period the Saxon began to assume a form in which the beginning of the present *English* may be discovered; it was thus rendered by pope Adrian, an Englishman, in rhyme:

" Ure Fader in heaven rich,
" Thy name be hayled ever lich,
" Thou hing us thy michell blisse:
" Als hit in heaven worthe
" Evar in yearth beene it also," &c.

About 100 years after, in the time of Henry III. it was translated thus:

" Fadir that art in heaven blisse,
" Thin halge nam it wurth the blis,
" Comen to mist thy kingdom,
" Thin holy will be it all soon,
" In heaven and in erdh also," &c.

Two hundred years after, under Henry VI. it was rendered thus:

" Our Fadir that art in heavens, halewid be thi
" name, thi kingdom come to thee, be thi will
" don in eerthe, as in hevene," &c.

Dr. Hickes furnishes an extraordinary specimen of the *English*, as spoken in the year 1385, in the Testament of Lucas Serpent, which we shall the rather entertain the reader with, as it is on this very subject, the *English* tongue; and contains not only the history, but the reasons of those changes and differences that is:

" As it is knowne how many manner people beeth in this
" londe; there beeth also so many divers languages and
" tongues. Notheless Welsh he nam and Scots that beeth
" nowght medled with other nations, beldeth wel nyh
" hir first language and speche: but sif the Sessiles that
" were sometime confederat and wonid with the Pictes

" drawe

" drawe somewhat after hir speche; but the Flemynges
" that woneth in the weste side of Wales, haveth left
" her strange speche, and speketh Sexonliche now. Also
" Englisshe men, they had from the bygynnynge thre
" maner speche: northerne, southerne, and middel
" speche in the middel of the londe, as they come of
" three maner of people of Germania: nothelefs by
" commyxtion and medlynge first with Danes, and
" afterwards with Normans, in meny the contrary lon-
" gage is apayred [corrupted]. This apayrynge of the
" burthe of the tunge is bycause of twelc thynges, oon
" is for children in scole agenst the usage and maner of
" all other nations, beeth compelled for to leve hire
" own longage, and for to construe hir lessons and here
" thynges in French, and so they haveth lerne Normans
" come first into Engelond. Also gentlemen children
" beeth taught to speke Frenische from the tyme that
" they beeth rokked in here cradel, and kunneth speke
" and play with a childes broche; and uplondisshe men
" will likke hymself to gentlimen, and fondeth with
" grete besynesse for to speke Frenshe to be told of.
" It sit seemeth a greet wonder how *Englisshe* men and
" her own longage and tonge, is so diverse of sown
" in this oon ilonde: and the longage of Normandie is
" comlynge of another lond, and hath oon manner soun
" amonge alle men that speketh hit arigt in Engelond.
" Also of the forsaid Saxon tonge that is deled [divided]
" a three, and is abide scarceliche with few uplondisshe
" men, is greet wonder. For men of the est, with
" men of the west, is, as it were, under the same par-
" tie of hevene acordeth more in sownynge of speche,
" than men of the north, with men of the south.
" Therefore it is that Mercii, that beeth men of myddel
" Engelond, as it were partenets of the endes, under-
" stondeth bettre the side longages northerne and south-
" erne, than northern or southerne understondeth
" either other. All the longage of the Northumbers,
" and specialliche at York, is so scharp, slitting and
" frotynge, and unschape, that we southerne men may
" that longage unnethe understonde. I trow that that
" is by cause that they beeth nyh to strange men and
" nations, that speketh strongliche, and also bycause
" that the kinges of Engelond wonneth alwey fer from
" that cuntry." &c.

The first of our authors who can properly be said to have written *English*, was sir John Gower, who, in his Confessio of Lover, calls Chaucer his disciple.

How the *English* stood about the year 1400, may be seen in Chaucer, who refined and improved it very considerably; though he is charged with the affectation of mixing too many French and Latin words with his *English*, and by that means, with too much altering and corrupting the primitive language.

In the year 1537, the Lord's Prayer was printed according to the following version:

" O oure Father which arte in heven, halowed be
" thy name: let thy kingdome come, thy will be
" fulfilled as well in erth as it is in heven," &c.

Where the reader will observe the diction almost brought to the present standard; the variations being principally in the orthography. See an historical view of the progress of the *English* language, with specimens at different periods, from the age of Alfred to that of Elizabeth, in the Introduction to Dr. Johnson's *English* Dictionary, vol. i. fol.

Spencer, who lived in the same age, contributed not a little to the improvement and refining of the tongue: he threw aside abundance of the outlandish ornaments, and wrote a purer *English*, yet with more elegance and variety than had been known before. He was succeeded by Shakespeare, Ben Johnson, lord Bacon, Milton, Cowley, Waller, Tillotson, Dryden, Addison, and Pope, &c. whose works are in every body's hands; and by whom the language has been transmitted to us under all its present advantages.

The perfections ascribed to the *English*, and that in a degree superior to any of the modern tongues, are, 1. That it is very strong and significant; to which our finely compounded words, formed on the model of the Greeks, do not a little contribute.

2. Copious; of which Mr. Greenwood gives us instances in the word striking; which we have above thirty different synonymous expressions for; as *to smite, bang, beat, baff, buffet, cuff, hit, thump, thwack, slap, rap, tap, kick, spurn, kick, pelt, pummel, punch*, &c. and the word *anger*, for which he enumerates above forty. So we say *to seeth* or *boil* flesh, *stew* prunes, *poche* eggs, *coddle* apples, *bake* bread; for which expressions, *to seeth, stew, poche, coddle*, and *bake*, the Latine, with all the boasted copia of the tongue, have only one word, *coquere*; and the French, as much as they abound with terms of cookery, not many more; the word *cuire* serving indifferently for *seething, boiling, baking, stewing*, and *coddling*.

3. Musical and harmonious; in which respect *Mr.* Dennis makes no scruple to assert it superior even to the French. This, which some may think strange, he proves hence, that we have blank verse which is harmonious by mere force of numbers and quantity; whereas the French have long ago desisted from all pretensions to poetical numbers, without the assistance of rhyme.

It may be added on this last head, from Mr. Wellstead, that the *English* has many measures, the iambic and trochee, for instance, in common with the Greek and Latin; an advantage arising from the variation of the accent; and that rhyme is peculiarly natural to it, varying itself to the ear with excessive sweetness; not to mention the cæsuras, pauses, transpositions, and numberless other graces, which the *English* versification is capable of, probably beyond every other living language.

Some object to the *English*, that it consists too much of monosyllables; which others make a piece of merit, as it argues the greater antiquity, if what Salmasius says be true: *Certum quippe est, linguas omnes, quæ monosyllabis constant, cæteris ejus originem loco habuisse, et has esse veterrimi Græci absconditi heroas, ac reperiri fere in omnibus fere, and such as affected antiquity.* De Re Hellenisti.

But we have a further advantage from our monosyllables, viz. *conciseness*; as we are hereby enabled to express more matter in the same compass of letters than any other modern tongue. The only thing we suffer by it, is, something in point of softness and numbers; and yet we have verses composed wholly of monosyllables, that do not want harmony; as that of Creech,

" Nor could the world have borne so fierce a flame."

Others object to our language, that it does not equal the softness, the delicacy, of the more southern languages, of France, Spain, and Italy. It seems to retain somewhat of the Gothic roughness of the people who framed and introduced it; the soil and climate it was planted in, not tending much to mellow and refine it.

To this purpose does Dr. Swift speak, who accounts for the effect hence, that the Latin tongue was never in its purity in our island; and besides, it was removed, in its imperfect state, before it could have time to incorporate with the language of the country, and subdue and soften it, as it did in the other provinces of France and Spain, &c. But it is to be observed, that upon the whole, this, supposing it true, does not lie as an objection against the languages, but the people: our manners are also less polished than some of our neighbours; we are not yet arrived at that pitch of moleste, of delicatesse, of loupelesse, which we censure in them; and it is but just our language correspond with the rest of our character.

Mr. Wellstead is of opinion, that the *English* language is not capable of a much greater perfection than it has already attained. We have trafficked, he observes, with every country for the enriching it; the ancients and moderns have both contributed to the giving it splendor and magnificence; the fairest cyons that could be had from the gardens of France and Italy, have been grafted on our old stocks, to refine the savageness of the breed; we have laid aside most of our harsh, antique words, and retained few but those of good and sound energy: the most beautiful polish is at length given our tongue that it will bear, without destroying and altering the very basis and ground-work of it; its Teutonic ruft is worn away, and little or nothing is wanting either of copiousness or harmony. He goes on to argue the maturity and perfection of the *English*, from another very extrinsic principle, viz. by comparing the time and circumstances of the improvements made since the first reformers of it, with those of the Greek, Latin, French, and other tongues that confessedly have arisen to their height.

Every civilized nation, that author thinks, has its classical age; and he suggests, that the *English* are not far from it. So that what remains to be done for the *English* tongue, should not be to advance, but to fix it where it is, and prevent its declining. There is, in effect, a point of perfection, which when a language has once arrived at, it cannot exceed, though it may degenerate from it; and thus it happened to the two finest languages that the world has known.

It may seem odd to talk of fixing so unstable a thing as language: the Greek liturgies of St. Basil, and St. Chrysostom, still used in that church, the one for solemn, the other for common days, have been a long time unintelligible to the people; so much is the Vulgar Greek degenerated from its original purity! Polybius testifies, that the articles of truce between the Romans and Carthaginians could scarce be understood by the most learned Roman antiquaries, three hundred and fifty years after the time in which they were made. In effect, from the days of Romulus, to those of Julius Cæsar, the Latin was perpetually changing; and what was written three hundred years before Tully, was as unintelligible in his time as

the *Engliſh* and French of the ſame period are now; and theſe two have changed as much ſince William the Conqueror, in about ſeven hundred years, as the Latin appears to have done in a like term.

Whether our language will decline as faſt as the Roman did, may admit of ſome doubt; there being many circumſtances in the affairs of that nation, which contributed to that ſpeedy corruption, that may not, in all probability, find place among us. The French, for about a century paſt, has been poliſhing as much as it will bear; and it appears to be now declining, by the natural inconſtancy of that people, and the affectation of ſome late authors, to introduce cant words, which is the moſt ruinous corruption in any language. But without ſome ſuch conſideration, there does not ſeem any abſolute neceſſity, why a language ſhould be perpetually changing.

We find examples to the contrary: from Homer to Plutarch, are above a thouſand years; and ſo long, at leaſt, Dr. Swift thinks, we may allow the purity of the Greek; The Grecians ſpread their colonies round all the coaſts and iſlands of Aſia Minor, and the Ægean ſea, where the language was preſerved entire for many ages after they themſelves became prowinces to Rome, and were overrun by the barbarous nations. The Chineſe have books in their language above two thouſand years old; neither have the frequent conqueſts of the Tartars been able to alter it. And the German, Spaniſh, and Italian, have admitted few or no changes for ſome ages paſt.

On ſuch conſiderations, that author moved the then prime miniſter, the earl of Oxford, to eſtabliſh a ſociety, or academy, for the ſettling, and aſcertaining, the purity of our tongue; to ſet a mark on the improprieties which cuſtom has made familiar, to throw out ridiculous phraſes and words, to correct others, and perhaps retrieve ſome others now grown obſolete, and to adjuſt the orthography, pointing, &c.

Without ſome ſuch means, he complains, that the ſame any writer can expect will be ſo ſhort and ſcanty, as by no means to be a ſufficient motive to call forth, and engage a man to exert his genius. Our language is chiefly confined to theſe two iſlands; and it is hard our authors ſame ſhould be limited in time as well as place. Were it not for the Bible and Common-prayer, we ſhould hardly have been able to underſtand any thing written a hundred years ago.

It is a melancholy reflexion, that Petrarch ſtill ſpeaks good Italian; whereas Chaucer, who lived an hundred years later, is not to be underſtood by an Engliſh reader without a Saxon and French gloſſary. And what ſecurity has Dryden himſelf, while things continue on their preſent footing, that he ſhall not in a like ſpace of time become as obſolete as Chaucer is?

Grammars and dictionaries, with whatever care and judgment they are compoſed, will prove but a feeble ſtay to a fleeting language, unleſs they have ſome extraordinary ſanction and authority. And, what is to be lamented, ſuch writings have contributed to the corruption almoſt as much as the perfection of our tongue.

Dr. Gill, Ben. Johnſon, and Hexham, it is certain, by forcing the *Engliſh* tongue to the Latin method, have clogged and perplexed it with abundance of uſeleſs precepts, concerning caſes, genders, and declenſions of nouns, tenſes, moods, and conjugations of verbs, and other things, which our language has nothing to do with. Nor have even Dr. Wallis, Greenwood, &c. though ſenſible of the fault in thoſe others, been able wholly to keep clear of it themſelves.

ENGLISH, *Borough*. See BOROUGH.

ENGONASIS, Ἐγγονασις, in *Aſtronomy*, Hercules: one of the northern conſtellations. See HERCULES.

ENGOUTED, in *Falconry*, is ſaid of a hawk's feathers, when they have black ſpots in them.

ENGRAFTING, GRAFTING, or GRAFFING, in *Agriculture*, and *Gardening*, the art, or act, of inſerting, or fixing, a cyon, ſhoot, or bud of one tree, in the ſtock of another; in order to correct, and improve its fruit.

Engrafting is the art of applying a *graft*, or ſhoot, of one plant, to the ſtock of another; in ſuch manner, as that the ſap paſſing freely through both, the tree *grafted* on may produce the ſame kind of fruit with that whence the *graft* is taken.

Engrafting only differs from *inoculation*, in this, that the latter is performed when the ſap is at the higheſt, in ſummer; and the former before it riſes, at leaſt in any quantity.

Engrafting is one of the principal operations in gardening, and that whereon the goodneſs of great part of our fruit greatly depends.

It is very extraordinary, that the ſeeds, or kernels, or ſtones of a fruit, as an apple pear, peach, plum, cherry, &c. being ſown, degenerate in the ground; ſo that the tree ariſing from it is of another kind, a ſort of wilding, haſtier, ſourer, and coarſer, than that of the parent tree. To correct this, trees thus reared muſt always be *grafted* from other better kinds.

Apples are commonly raiſed by *engrafting* the intended kinds on crab-ſtocks, procured by ſowing the kernels; ſo are pears procured by *grafting* on the wild pear-ſtock; though for dwarf, or wall-trees, they generally chooſe to *engraft* on the quince-ſtock.

They will alſo do if *grafted* on the white-thorn. Peaches are produced by *grafting* on an almond or plum-ſtock. Indeed, in this fruit, it ſometimes happens, that the ſtone ſown produces better fruit than that from which it was taken; but this is not common; beſide that the tree in ſuch caſe is long before it comes to bear. Plums are raiſed by *engrafting* on a damaſcene, or wild plum-ſtock; and cherries, on the black cherry, or merry-ſtock, raiſed from ſtones.

Our beſt gardeners, likewiſe, *engraft* their leſs kindly trees from other better of the ſame ſort, to mend them; as alſo, the ſmaller and ſingle flowers, as gilliflowers, &c. from the larger and finer. *To produce ſtocks* for engrafting *on*, ſee STOCKS. For the choice of *grafts* or *cyons*, ſee GRAFT.

The curious furniſh us with other extraordinary and anomalous inſtances of *engrafting*; as of apples on plane, elder, thorn, cabbage-ſtalk, &c. And the like of pears, &c. pears on apple-trees, on elms, &c. cherries on the laurel, coral-berries on the plum; beech on the cheſtnut, oak on the elm, gooſeberry on the currant, the vine on the cherry-tree, &c.

Inſeritur haud exiguis, portuque ſecuto
Fingit adoptivus virginis ora puer. Auſon.

Ev'n Daphne's coyneſs thou doſt mock,
And weeſt the cherry to her ſtock. Cowl. to Evel.

——— *Mutatumque inſita mala*
Ferre pirum, & prunis lapidoſa rubeſcere corna.
Virg. Georg. lib. ii. ver. 33.

——— *Steriles platani, malos geſſere valentes;*
Caſtaneæ, fagus; ornuſque incanuit alno
Flore pirus; glandemque ſues fregere ſub ulmis.
Id. Ibid. ver. 70, &c.

The origin and invention of *engrafting* is differently related by naturaliſts. Theophraſtus tells us, that a bird having ſwallowed a fruit whole, chanced to caſt it forth into a cleft, or cavity, of a rotten tree; where mixing with ſome of the putrefied parts of the wood, and being waſhed with the rains, it budded, and produced within this tree another tree of a different kind. This led the huſbandman to certain reflections, from which, ſoon afterwards, aroſe the art of *engrafting*.

Pliny ſets the thing in a different light: a countryman having a mind to make a paliſade in his grounds, that it might endure the longer, bethought himſelf to fill up, and ſtrengthen the bottom of the paliſade, by running, or wattling it with the trunks of ivy. The effect of this was, that the ſtakes of the paliſade, taking root, became *engrafted* into the trunks, and produced large trees; which ſuggeſted to the huſbandman the art of *engrafting*.

The reaſon, or philoſophy, of *engrafting* is ſomewhat obſcure; and had not hazard given the firſt hint, all our knowledge of nature would never have led us to it. The effect is ordinarily attributed to the diverſity of the pores, or ducts, of the *graft*, from thoſe of the ſtock, which change the figure of the particles of the juices in paſſing through them to the reſt of the tree.

Mr. Bradley, on occaſion of ſome obſervations of Agricola, ſuggeſts ſomething new on this head: the ſtock *grafted* on, he thinks, is only to be conſidered as a fund of vegetable matter, which is to be ſtrained through the cyon, and digeſted, and brought to maturity, as the time of growth in the veſſels of the cyon directs. A cyon, therefore, of one kind, *grafted* on a tree of another, may be more properly ſaid to take root in the tree it is *grafted* in, than to unite itſelf with it: for it is viſible, that the cyon preſerves its natural purity and intent, though it be fed and nouriſhed with a mere crab; which is without doubt occaſioned by the difference of the veſſels in the cyon from thoſe of the ſtock; ſo that *grafting* may be juſtly compared to planting.

In proſecution of this view of that ingenious author, we add, that the natural juices of the earth, by their ſecretion and comminution, in paſſing through the roots, &c. before they arrive at the cyon, muſt doubtleſs arrive there half elaborated and concocted; and ſo diſpoſed for a more eaſy, plentiful, and perfect aſſimilation and nutrition; whence the cyon muſt neceſſarily grow and thrive better and faſter than if it were put immediately in the ground, there to live on coarſe diet, and harder of digeſtion; and the fruit produced, by this farther prepa-

preparation in the cyon, muſt be finer and farther exalted, than if fed immediately from the more imperfectly prepared and altered juices of the ſtock.

The cyon, to ſay no more, is ſomewhat in the condition of the fœtus in utero, fed from the mother's blood; or, at leaſt, it is in that of the infant after exclusion, fed with the mother's milk.

Tools neceſſary for grafting. In order to *grafting*, a perſon muſt be provided with the following tools. 1. A neat and ſmall hand-ſaw to cut off the heads of large ſtocks. 2. A ſtrong knife with a thick back, to make cleſts in the ſtocks. 3. A ſharp pen-knife to cut the *graft*. 4. A *grafting* chiſſel and a ſmall mallet. 5. Baſs-ſtrings, or elſe woollen yarn, to faſten on the *graft* with; and, finally, a quantity of clay, which ſhould be prepared a month before it is uſed, and kept turned and worked about every day like mortar. The beſt mixture for this matter is, a quantity of ſtrong, fat, and viſcous loam muſt be got, and into this muſt be well beat and mixed ſome ſtone-horſe dung, and ſome chopped ſtraw cut very ſhort and finally finally, a quantity of common ſalt muſt be thrown in; this muſt be mixed up and beat together into a paſte with water, but it muſt not be expoſed to the froſts. This is equally proper to be employed for all the different ſorts of *grafting*. Miller.

Some perſons have lately uſed a compoſition of turpentine, bees-wax, and roſin, melted together, which, applied round the graft about a quarter of an inch thick, will keep out the air more effectually than clay, be hardened by cold, as it reſiſt the froſt, and fall off, when melted by the ſummer heat, without any trouble.

Principal kinds of grafting are, *grafting* in the cleft, *grafting* in the rind, white *grafting*, *grafting* by approach, ſcutcheon *grafting*, root *grafting*, reiterated *grafting*, *grafting* on branches, &c.

GRAFTING *in the cleft*, or *ſtock*, called alſo *ſlit*-GRAFTING, is the moſt ancient and ordinary way. It is chiefly uſed for middle-ſized ſtocks, from one to two inches diameter. Its ſeaſon is in the months of February and March. The method, as now practiſed, is thus: the head of the ſtock being fawn, or cut off, ſmooth and clean, with a ſlope, a perpendicular cleft is made therein, nearly two inches deep, with a ſtrong knife or chiſſel, as near the pith as may be to miſs it. In this cleft, the *grafting* chiſſel, or wedge is put to keep it open. The *graft*, or cyon, is prepared by cutting it aſlope, in form of a wedge to ſuit the cleft; only leaving a ſmall ſhoulder on each ſide; and, when cut, is to be placed exactly in the cleft, ſo as that the inner bark of the cyon may aptly and cloſely join to the inner part of the bark, or rind, of the ſtock; in the dextrous performance of which the chief ſecret conſiſts. If the cleft pinch too tight, a ſmall wedge may be left in it to bear the ſtreſs. And, laſtly, the cleft is covered over with clay, leaving two eyes of the cyon above the clay for ſhooting; or rather, as M. Gentil adviſes, with moſs, or freſh bark of a tree bound on with oſier.

The reader, who would have this in more elegant terms, may be furniſhed from Virgil, Georg. ii. ver. 78, &c.

Aut rurſum enodes trunci reſecantur & alti
Fiuitur in ſolidum cuneis via: deinde ſuccos
Plenius immittuntur; nec longum tempus, & ingens
Exit ad cœlum ramis felicibus arbos,
Miratuque novas frondes, & non ſua poma.

GRAFTING *in the rind*, or *ſhoulder*-GRAFTING, called alſo *ſlicing*, and *packing*, is practiſed in the latter end of March, or beginning of April. The method is as follows:

The top of the ſtock is cut off in a ſmooth, ſtraight place; then the cyon, or *graft*, is prepared by cutting on one ſide from the joint, or ſeam, down ſlopewiſe, making the ſlope about an inch long, and obſerving its bent, that ſo, when the cyon is fixed to the ſtock, it may ſtand nearly upright. At the top of the ſlope, they make a ſhoulder, whereby it is to reſt on the ſlope of the ſtock. The whole ſlope is to be plain and ſmooth, that it may lie even to the ſide of the ſtock. As to the length of the cyon, for a ſtandard-tree, it may lie about four inches from the ſhoulder; but for a dwarf, or wall-tree, ſix inches. The cyon being prepared, the outſide is applied to the weſt, or ſouth weſt-ſide of the ſtock, and its length and breadth meaſured thereon; which done, the bark of the ſtock is cut away to thoſe dimenſions, that the cut part of the cyon may fit it. Wherein, regard is to be had to the bigneſs of the ſtock, and the thickneſs of the bark, to proportion the length and breadth of the chip thereto; otherwiſe the paſſages of the juice in the ſtock and cyon will not meet. Laſtly, laying the cut part of the cyon on that of the ſtock, they bind them together with woollen yarn, and cover the whole with clay an inch above, and as far below the ſtock's head; working it round the cyon; till it become ſharp at top, that the rain may run down it.

This method has ſeveral advantages over the former: as that the wound heals up ſooner; and that, in the mean time, it is in leſs danger from the weather; that it does leſs injury to the ſtocks and *grafts*, as avoiding thoſe ſevere ſplittings and pinchings; that the bark is more eaſily placed in the paſſage of the ſap here, than in the cleft; that the *graft* thrives and ſhoots with greater vigour and bears ſooner, in this way than in that; and that it is practicable on ſmaller ſtocks than the other, which muſt have a good body and conſiſtence, before they can bear cleaving. See *Green*-GRAFTING.

GRAFTING *in the bark* is performed thus: prepare the ſtock and cyon, as in *grafting in the rind*; but inſtead of cutting the bark of the ſtock, ſlit the ſame on the ſouth-weſt ſide, from the top, almoſt as long as the ſloped part of the cyon, and at the top of the ſlit looſen the bark with the top of your knife. Thruſt an inſtrument made of ivory, ſilver, or the like, and formed at the end like the ſlope-end of the cyon, but much leſs, down between the bark and wood to make room for the cyon; which being put in, the bark is to be ſo managed, as that it may fall cloſe to the ſtock, and edges of the cyon.

GRAFTING by approach or adjaciation. See ADJACIATION and INARCHING.

All thoſe trees which are of the ſame tribe, that is, which agree in their flower and fruit, will take upon one another; thus all the nuts may be *engrafted* on one another; as may alſo all the plums, and all that are allied to them; as the almond, peach, nectarine, and the like; but as theſe generally loſe a great deal of gum in the *grafting*, the operation of inoculation is much more proper for them.

All the trees which bear cones will ſucceed very well on one another, even though ſome ſhed their leaves in winter, and others do not. Thus the cedar of Lebanon and the larch tree do very well on one another; but theſe, becauſe they abound ſo greatly in reſin, muſt be *grafted* by approach, becauſe the reſin of the *graft* being loſt from it before it is ſet into the ſtock, makes it otherwiſe often miſcarry.

Bad weather will often deſtroy the hopes of the beſt operator; otherwiſe with theſe regulations the whole generally ſucceeds very well; and is not only of uſe for the propagating many exotic plants, but even will make very tender ones bear our climate, by placing them on the hardier ſtocks of the ſame kind.

Whip-GRAFTING, or *Tongue*-GRAFTING, is a ſort of *grafting* in the rind, proper for ſmall ſtocks from an inch diameter to a quarter of an inch. Mr. Miller ſpeaks of it as the moſt effectual way of any, and that moſt in uſe.

In this, the ſtock and cyon are always to be of the ſame bigneſs. The cyon to be ſloped off a full inch or more; and the like is to be done to the ſtock; and ſo the one to be tied to the other. Otherwiſe, the top of the ſtock being cut off, a ſhoulder is to be made in the *graft*; and the reſt to be performed as already ſhewn under *grafting in the rind*.

This method is alſo improved by what they call *tipping*, or *tonguing*; which is, the making of a ſlit with a knife in the bare part of the ſtock, downwards; and the like in the ſloped face of the cyon, upwards: then joining them, by thruſting one ſlice into the other, till the bare place of the cyon cover that of the ſtock; then there ſhould be a ligature of baſs to faſten the cyon, ſo that it may not eaſily be diſplaced, which ſhould be covered with clay.

Side-GRAFTING. In this, the cyon is prepared as in *whip-grafting*; but the head of the ſtock is not cut off. Only, from a ſmooth part on the weſt ſide, ſo much of the bark is pared off as the cyon will cover; then ſitting both cyon and ſtock, as in the laſt article, they bind the two together, and cloſe them up with clay. At the year's end, the top of the ſtock is cut off at the grafted place, ſlopewiſe; and the place is covered with clay.

Scutcheon-GRAFTING, is another method of *grafting* in the rind, practiſed in June, July, and Auguſt, when the bark will not part from the ſtock. It is performed by ſlitting the bark of the ſtock in form of the capital letter T, looſening it with the point of a knife, and clapping in a cyon, prepared as above. See INOCULATION and SCUTCHON.

Crown-GRAFTING, is when four or more *grafts* are placed round the ſtock, between the bark and the rind, ſomewhat in the manner of a crown. This is only practiſed in the larger trees which are capable of receiving a number of *grafts*, and are too big to be cloven. The method is in all reſpects the ſame as that already delivered for *grafting in the rind*.

Root-GRAFTING, is a modern invention, treated of at large by Agricola; its intention is ſomewhat different from the former, being for the propagation, or multiplication of plants.

To perform this, take a *graft*, or ſprig, of a young tree, which

which you intend to propagate; and a ſmall piece of the root of another tree of the ſame kind, or of a kind very like it; or elſe pieces of roots cut off other trees, in tranſplanting, and *whip-graft* them together; obſerving, that the two butt-ends of the *graft* and root be joined, and that the rind of the root join that of the *graft*. Theſe may, afterwards, be planted out at pleaſure, and the piece of root will draw the ſap, and feed the *graft*, as the ſtock does in the other way.

This way of propagation is very eaſy and expeditious; roots being more plentiful than ſtocks: by this method the pieces of roots of one crab-ſtock, or apple-ſtock, will ſerve for twenty or thirty apple *grafts*, and the like of other trees. The ſame is alſo an excellent way for raiſing of tender trees, that will hardly bear being *grafted* in the ſtock. Add, that trees thus *grafted*, bear ſooner, and are more eaſily dwarfed, than thoſe done in any other way.

Reiterated GRAFTING, or *grafting by a double*, or *triple inciſion*, is another method mentioned by Agricola: to perform which, firſt *graft* a good cyon on a ſtock, and cut it away to one half, or a third part; then fix another *graft* to it, of a better kind, and a third to that; for ſtill the eſteem a tree is *engrafted* the finer fruit it produces.

By this method, that author aſſures us, he produced muſcat pears, that were admirable; making, at firſt, uſe of a ſtock *grafted* with a pound-pear, on which he *grafted* a ſummer bon chretien; and when the branch of this latter had ſhot, he *grafted* on it a cyon of bergamot; which he alſo cut, and *grafted* on it a cyon of a muſcat pear.

ENGRAFTING *of branches*, Agricola mentions as a very certain and profitable operation, beſt practiſed on large, full-grown, and even old trees.

To do this, half or more of the branches muſt be lopped off, and *grafts* of three or four years old applied to them; taking care to have ſtakes, or other things, to ſupport them againſt the wind, &c.

He adds, that by this method, you will have, perhaps, the ſame year, as leaſt the ſecond or third, ſuch a quantity of fruit, as the youngeſt and ſoundeſt tree would hardly produce.

The facility with which *grafts* take place, and grow on proper ſubjects, is well known; there are, however, many accidents and uncertainties attending them in their different periods. Some periſh immediately, ſome after appearing healthy for many months, ſome even after years of health. Of theſe laſt ſome die without the ſtocks ſuffering any thing; others periſh together with it. It is very certain that the greater part of *grafted* trees do not live ſo long as they would have done in their natural ſtate, yet this is no unexceptionable rule, for there are ſome which evidently live the longer for this practice; nay, there are inſtances of *grafts*, which being placed on ſtocks naturally of ſhort duration, live longer than when placed on thoſe which are more robuſt and laſting. Theſe are irregularities which have been little conſidered hitherto, though they happen in a practice, the advantages of which are very great. One great requiſite for the ſucceeding of any *graft* is, that it be in its own nature capable of ſo cloſe and intimate an union with the ſubſtance of the ſtock, that it becomes, as it were, a natural branch of it. If all trees reſembled one another in their ſtructure and juices, if their ſolid parts were all of the ſame figure, and their ſap all of the ſame nature and conſiſtence, their veſſels all of the ſame diameters, and their elaſticity, and the number of the tracheæ equal in all, and in all filled with the ſame quantities of air; if trees were alike in theſe particulars, probably *grafts* of all trees would ſucceed upon one another, but this is by no means the caſe.

The *grafts* of the almond on the plum, and of the plum on the almond, always grow very vigorouſly for the firſt year, and give all the appearance imaginable of ſucceeding entirely, yet they always periſh in the ſecond, or elſe in the third year. The almond graft upon the plum ſtock always puſhes out very vigorouſly at firſt, but the part of the ſtock immediately under the *graft* grows ſmaller, and periſhes; the *graft* abſorbing too much of its juices, and the *graft* neceſſarily periſhes with it. The decay of the whole generally happens early in the ſpring, and that plainly from the different ſeaſon of the natural ſhooting of the two trees, the almond puſhing very vigorouſly, and conſequently draining the ſtock of its juices, at a time when, according to its nature, the juices are but in ſmall quantity in it, and the ſap does not begin to aſcend. The *grafts* of the plum on the almond are, from the ſame cauſe, furniſhed with an abundance of ſap, which they have at that time no occaſion for, and conſequently they as certainly periſh of repletion, as the other of inanition. Mem. Acad. Par. 1730.

The peach *grafted* on the plum ſucceeds excellently, and lives longer than it would have done in its natural ſtate. The reaſon of which is this: the peach is a tender tree, it ſhoots with great vivacity, and produces more branches than the root is able to maintain, which is the reaſon why peach-trees are uſually full of dead wood, and often their large branches periſh, and ſometimes their whole trunk; on this occaſion, the plum being a ſlow ſhooting tree, communicates its virtue to the *graft*, and the peach conſequently ſends out ſhoots, which are more robuſt and ſtrong, and are no more in number than the root is able to ſupply with nouriſhment; hence the tree is more ſtrong and laſting. Miller.

See an account of methods of *engrafting* for improving and haſtening the fruit, under FRUIT-*trees*.

ENGRAFTING *of the ſmall pox*. See INOCULATION.

ENGRAILED, or INGRAILED, in *Heraldry* (from the French *grêle*, *hail*) is when a thing is preſented with its edges ragged, or notched, ſemicircularly, as if broken by ſomething falling on it. See *Tab.* II. *Heraldry fig.* 57. See INDENTED, and INVECTED.

Speliman expreſſes it in Latin by *imbricatus*; others by *ingrediatus*; and others by *ſriatus*.

ENGRAVERS. See ENGRAVING.

By 8 Geo. II. cap. 13. *engravers* that ſhall invent, deſign, and engrave prints, have the ſole right of printing them for fourteen years, which are to be engraved with the names of the proprietors; and others copying and ſelling ſuch prints, though by varying &c. without their conſent, ſhall forfeit 5*l.* for every print, and alſo the plates and ſheet, &c. This privilege was continued for twenty-eight years by 7 Geo. III. cap. 38. And by 17 Geo. III. cap. 57. double coſts are given.

ENGRAVING, or GRAVING, the art, or act, of cutting metals, and precious ſtones, and repreſenting figures, letters, and other matters, thereon.

The word is a compound of the prepoſition *en*, *in*, and γραφω, *I write*. Though Menage, after Salmaſius, derives it from the Latin *cavare*, *to hollow*; others from the Latin, *graphiare*; and others from the German, *graben*, q. d. *effodere*, *to dig out*. In Latin it is called *ſculptura*, and *cælatura*.

Engraving is properly a branch of ſculpture; though with us it generally ſtands contradiſtinguiſhed from ſculpture; as the latter, popularly called *carving*, expreſſes the forming of figures, &c. embolſſed, or in relievo; and the latter, thoſe indented, or in creux.

Among the French, the term *engraving*, *gravure*, is of larger extent. It includes all kinds of ſculpture, both that performed with the chiſſel and knife, on marbles and woods in relievo; and that in metals, ſtones, &c. with the graver indented.

Engraving is divided into ſeveral branches, according to the matters it is practiſed on, and the manner of performing it. The original way of *engraving* on wood is now diſtinguiſhed by the name of CUTTING *in wood*; that on metals with aqua fortis, is called ETCHING; that by the knife, burniſher, punch, and ſcraper, MEZZOTINTO; that on ſtones, for tombs, &c. *carving*, or *ſtone-cutting*; and laſtly, that performed with the graver on metals, as copper, braſs, ſteel, ſilver, &c. as alſo on precious ſtones, cryſtals, &c. retains alone the primitive denomination of *engraving*.

Engraving is an art, for the greateſt part, of modern invention; having its riſe no earlier than the middle of the fifteenth century. The ancients, it is true, practiſed *engraving* on precious ſtones and cryſtals, with very good ſucceſs; and there are ſtill many of their works remaining, equal to any production of the later ages. But the art of *engraving* on plates, and blocks of wood, to aſford prints, or impreſſions, was not known till after the invention of painting in oil.

The diſcovery is aſcribed to Maſo Finiguerra, a goldſmith of Florence, about the year 1460; who having uſed to take impreſſions of every thing he caſt in clay, and to caſt melted ſulphur in this mould, at length perceiving that what came out of the mould was marked with the ſame figures as his plate, by the black which the ſulphur had taken from his graving, he tried to do as much on ſilver plates, with wet paper, by rolling it ſmoothly with a roller which alſo ſucceeded. This was the origin of producing impreſſions upon paper in lines, as prints are now done; but the art of *engraving* them ſeems to have been of earlier date. See PRINTING.

By him it is ſaid to have been communicated to Baldini, a goldſmith of the ſame city, who engraved ſeveral plates from drawings of Botticelli, and was afterwards aſſiſted by Andrea Mantegna, of Padua, who improved the art. However, the Germans pretend that this art was practiſed among them by Lupreche Rull, the maſter of Schoen, as early as the year 1450. Other German writers aſcribe the invention of it to Francis a Bocholt, who was immediately ſucceeded by Israel al Meckenick, and Martin Stock, Albert Durer's maſter. The Dutch pre-

tend that the art of taking off impreſſions on wood was diſcovered by Lawrence of Harlem, who died between the years 1435 and 1440; and that of *engraving* on copper by Peter Schoeffer, a printer of Mentz; and that it was carried into Germany and Italy by his workmen, when Mentz was taken in 1462.

However, the ſecret ſoon got abroad, and coming to the hands of Martin Schoen of Colmar, in Germany, who is ſaid to have practiſed this art from the year 1460 to 1470; Albert Durer, who was born at Nuremberg in 1470, and died in 1528; Lucas of Leyden, born in 1496, and who died in 1533; and Marco Antonio of Bologna, in the beginning of the ſixteenth century; they greatly improved it, and began to engrave on wood and copper, in which they ſucceeded to admiration. See Evelyn's Hiſtory of Chalcography.

ENGRAVING *in copper*, is employed in repreſenting diverſe ſubjects, as portraits, hiſtories, landſcapes, foliages, figures, buildings, &c. either after paintings, or after deſigns made for this purpoſe.

It is performed with the graver, dry point, or with aqua fortis. For the firſt, there needs but little apparatus, and few inſtruments. The plate you work on being well poliſhed (for the method of preparing which, ſee COPPER-*plate*), is covered over with a thin ſkin of virgin-wax, and on this the draught, or deſign, done in black lead, red chalk, or other ungummed matter, is laid, and rubbed down for the wax to take off. The deſign thus tranſferred upon the wax, is traced through on the copper, with a point or needle; then heating the plate, and taking off the wax, the ſtrokes remain; to be followed, heightened, &c. according to the tenor of the deſign, with the GRAVER, which is to be very ſharp, and well tempered.

The dry point, or needle, which has been of late much uſed in *engraving*, is a tool like an etching point, which being drawn hard on the copper, cuts a ſtroke, and raiſes a burr; the burr is ſcraped off, and there remains a ſtroke more ſoft and delicate than can be produced in any other way.

In the conduct of the graver and dry point conſiſts all the art; for which there are no rules to be given; all depending on the habitude, diſpoſition and genius, of the artiſt. However, ſome general obſervations and directions may not be improper. As the principles of *engraving* are the ſame with thoſe of painting, a perſon cannot expect to attain any conſiderable degree of perfection in this art who is not a good maſter of deſign; and therefore he ought to be well acquainted both with perſpective and architecture; for the former, by the proper degradations of ſtrong and faint colours, will enable him to throw backwards the figures and other objects of the picture or deſign which he propoſes to imitate; and the latter will teach him to preſerve the due proportion of its ſeveral orders, which the painter often entruſts to the diſcretion of the engraver. In order to preſerve equality and union in his works, the engraver ſhould always ſketch out the principal objects of his piece before he undertakes to finiſh them. Care ſhould be taken that the graver be carried level upon the plate, and be preſſed, as occaſion requires, with greater or leſs force, carrying the hand as evenly as poſſible. In drawing ſtraight lines, a leſs degree of preſſure ſerves for thoſe that are finer, and a greater is required to form the broader and deeper lines. In forming circular or curved lines, the hand and graver muſt be held ſteady, and the plate is to be moved upon the cuſhion under the graver. In large works a cuſhion is uſeleſs. The engraved work may be rendered more viſible, by rubbing it over with a roll of felt, dipt in oil. The ſtrokes of the graver ſhould never be croſſed too much in a lozenge manner, particularly in the repreſentation of fleſh, becauſe ſharp angles produce the unpleaſing effect of lattice work, and take from the eye the repoſe which is agreeable to it in all kinds of picturеſque deſigns: we ſhould except the caſe of clouds, tempeſts, waves of the ſea, the ſkins of hairy animals, or the leaves of trees, where this method of croſſing may be admitted. But in avoiding the lozenge, it is not proper to get entirely into the ſquare, which would give too much of the hardneſs of ſtone. In conducting the ſtrokes, the action of the figures, and of all their parts, ſhould be conſidered; and it ſhould be obſerved how they advance towards, or recede from the eye; and the graver ſhould be guided according to the riſings or cavities of the muſcles or folds, making the ſtrokes wider and fainter in the light, and cloſer and firmer in the ſhades. Thus the figures will not appear jogged; and the hand ſhould be lightened in ſuch a manner, that the outlines may be formed and terminated without being cut too hard: however, though the ſtrokes break off where the muſcle begins, yet they ought always to have a certain connection with each other, ſo that the firſt ſtroke may often ſerve by its return to make the ſecond, which will ſhew the freedom of the engraver.

In *engraving* the fleſh, the effect may be produced in the lighter parts, and middle tints, by long pecks of the gravers, rather than by light lines, or by round dots, or by dots a little lengthened by the graver, or, beſt of all, by a judicious mixture of theſe together.

In *engraving* the hair and the beard, the engraver ſhould begin his work by laying the principal grounds, and ſketching the chief ſhades in a careleſs manner, or with a few ſtrokes; and he may finiſh it at leiſure with finer and thinner ſtrokes to the extremities. When architecture, or ſculpture, is to be repreſented, except it be old and ruinous buildings, the work ought not to be made very black; becauſe, as edifices are commonly conſtructed either of ſtone or white marble, the colour, being reflected on all ſides, does not produce dark or brown ſhades, as in other ſubſtances. White points muſt not be put in the pupils of the eyes of figures, as in *engravings* after paintings; nor muſt the hair or beard be repreſented as in nature, which makes the locks appear flowing in the air; becauſe in ſculpture there can be no ſuch appearances.

In *engraving* cloths of different kinds, linen ſhould be done with finer and cloſer lines than other ſorts, and be executed with ſingle ſtrokes. Woollen cloths ſhould be engraved wide, in proportion to the coarſeneſs or fineneſs of the ſtuff, and with only two ſtrokes; and when the ſtrokes are croſſed, the ſecond ſhould be ſmaller than the firſt, and the third than the ſecond. Shining ſtuffs, which are generally of ſilk or ſattin, and which produce flat and broken folds, ſhould be engraved more hard and more ſtraight than others, with one or two ſtrokes, as their colours are bright or brown; and between the firſt ſtrokes other ſmaller muſt be joined, which is called interlining. Velvet and pluſh are expreſſed in the ſame manner, and ſhould always be interlined. Metals, as armour, &c. are alſo repreſented by interlining, or by clear ſingle ſtrokes. In architecture, the ſtrokes which form the rounding objects ſhould tend to the point of ſight; and when whole columns occur, it is proper to produce the effect as much as poſſible, by perpendicular ſtrokes. If a croſs ſtroke is put, it ſhould be at right angles, and wider and thinner than the firſt ſtroke. In *engraving* mountains, the ſtrokes ought to be frequently diſcontinued and broken, for ſharp and craggy objects; and they ſhould be ſtraight, in the lozenge manner, and accompanied with long points or dots; and rocks ſhould be repreſented by croſs ſtrokes more ſquare and even. Objects that are diſtant towards the horizon ſhould be kept very tender, and ſlightly charged with black. Waters that are calm and ſtill are beſt repreſented by ſtrokes that are ſtraight, and parallel to the horizon, interlined with thoſe that are finer; omitting ſuch places as, in conſequence of gleams of light, exhibit the ſhining appearance of water; and the form of objects, reflected from the water, at a ſmall diſtance upon it, or on the banks of the water, are expreſſed by the ſame ſtrokes, retouched more ſtrongly or faintly, as occaſion may require, and even by ſome that are perpendicular. For agitated waters, as the waves of the ſea, the firſt ſtrokes ſhould follow the figures of the waves, and may be interlined, and the croſs ſtrokes ought to be very lozenge. In caſcades, the ſtrokes ſhould follow the fall, and be interlined. In *engraving* clouds, the graver ſhould ſport, when they appear thick and agitated, in turning every way according to their form, and their agitation. If the clouds are dark, ſo that two ſtrokes are neceſſary, they ſhould be croſſed more lozenge than the figures, and the ſecond ſtrokes ſhould be rather wider than the firſt. The flat clouds, that are loſt inſenſibly in the clear ſky, ſhould be made by ſtrokes parallel to the horizon, and a little waving; if ſecond ſtrokes are required, they ſhould be more or leſs lozenge; and when they are brought to the extremity, the hand ſhould be ſo lightened, that they may form no outline. The flat and clear ſky is repreſented by parallel and ſtraight ſtrokes, without the leaſt turning. In landſcapes, the trees, rocks, earth, and herbage, ſhould be etched as much as poſſible; nothing ſhould be left for the graver but perfecting, ſoftening, and ſtrengthening. The dry point produces an effect more delicate than the graver can, and may be uſed to great advantage in linen, ſkies, diſtances, ice, and often in water, eſpecially in ſmall *engravings*. In moſt things it is proper to etch the ſhadows, only leaving the lighter tints for the dry point, graver, &c. Encyclopedie, art. GRAVURE; and Handmaid to the Arts, vol. ii. p. 63, &c.

The other inſtruments, beſides the graver and dry point, are, a CUSHION, or ſand-bag, to lay the plate on, to give it the neceſſary turns and motions: a burniſher, round at one end, and uſually flatniſh at the other, to rub out

flips and failures, and to soften the ſtrokes, &c. A ſcraper to pare off the ſurface, on occaſion; and a rubber of black cloth, or hat, to fill up the ſtrokes, that it may appear how the work proceeds.

To take off printed cuts, ſo that the outlines and principal ſtrokes may be exactly copied for graving, may be thus performed: if the *print* be not above a year or two old, the paper need only be moiſtened with water in the manner uſually practiſed for *printing* cuts; but if it be more ancient, it ſhould be laid to ſoak all night in water, and afterwards hung in the air till it becomes dry enough for the preſs. The paper thus prepared, is to be laid with its *greaſed* ſide next the plate, thinly caſed over with white wax, which is thus to be committed to the rolling preſs, whereby an impreſſion of the cut will be obtained. Boyle's Works abr. vol. i. p. 136.

ENGRAVING *in copper with aqua fortis*. See ETCHING.

ENGRAVING *in chalk* is the art of imitating or counterfeiting upon copper, drawings made with chalk on paper. This method of *engraving* was invented by M. Francis, to whom the king of France granted a penſion for the diſcovery. It is intended to form a kind of deception, ſo that the connoiſſeur may not be able, on the firſt inſpection, to diſtinguiſh between the original drawing and the engraving made in imitation of it; and it is extremely uſeful, as it ſerves to multiply copies of drawings left by thoſe maſters who excelled in the uſe of chalks, and thus to form and improve young artiſts, who could not have acceſs to the originals in the practice of drawing. This kind of *engraving* is not performed with the points of the graver, as is the uſual manner in copper-plate *engraving*, but by a mixture of varied and irregular dots, as being more proper to reſemble the grain produced by the chalks on paper, more or leſs ſoft. Every ſtroke of the chalks on paper may be conſidered as an infinite number of adjoining points, which are the ſmall eminences of the grain of the paper, touched by the chalk in paſſing over it. When the copper-plate has been poliſhed and varniſhed, or properly prepared, as in the common method of *engraving*, the drawing to be imitated may be counterproved on the varniſh of the plate. If this cannot be conveniently done, black lead pencil, or red chalk, muſt be applied to varniſhed or oiled paper, and by means of this chalk, or pencil, all the traces of the original will be tranſmitted to the varniſh. See CALQUING and ENGRAVING, above.

The outlines of the object muſt be formed in the etching by points, whoſe magnitude and diſtance muſt be determined by the quality of the ſtrokes in the original drawing. The artiſt may be provided with pointed inſtruments, or needles, of various ſizes, with ſingle or double points. In forming the light and ſhade, he ſhould diſtinguiſh between thoſe hatches which ſerve to expreſs the perſpective of the object, and thoſe which form the ground of it. The principal hatches ſhould be more ſtrongly marked, the middle tints, if etched, ſhould be marked lightly, or they may be left till the varniſh is taken off, and be perfected with a greater degree of ſoftneſs, by needles, or the point of the graver, as the original may require. There is nothing peculiar in the method of applying the aqua fortis in this kind of *engraving*; but it may be obſerved, that it ſhould not be left ſo long as to corrode the lighter parts too much; if the light parts are ſufficiently corroded, they may be ſtopped out with turpentine, varniſh, and lamp-black, mixed together, and the aqua fortis may be applied again to the ſtronger parts; for it will be no detriment to them, if the points which compoſe the ſhade burſt into one another, provided the extreme be avoided. When the work of the aqua fortis is finiſhed, and the varniſh taken off the copper, it will be neceſſary in the ſofteſt parts, ſuch as the fleſh, &c. to interſtipple with proper points; as an effect will be thus produced more delicate than it is poſſible to attain with the aqua fortis only; and the ſtrongeſt ſhades will require additional ſtrength, to be given them with ſmall ſtrokes of the graver. This ſort of *engraving* ſhould be ſcraped before it is finiſhed.

Drawings made with chalks of different colours may be imitated in this manner, if a plate be provided for every colour. Encyclopedie.

ENGRAVING *in aqua tinta* is the art of imitating upon copper drawings made with biſtre, or Indian ink.

ENGRAVING *in mezzotinto*. See MEZZOTINTO.

ENGRAVING *on precious ſtones*, is the repreſenting of figures, or devices, either in relievo, or indented, on diverſe kinds of hard, poliſhed ſtones.

The art of *engraving* on precious ſtones is one of thoſe wherein the ancients excelled; there being diverſe antique agates, cornelians, and onyxes, which ſurpaſs any thing of that kind the moderns have produced. Pyrgoteles among the Greeks, and Dioſcorides under the firſt emperors of Rome, are the moſt eminent engravers we read of: the former was ſo eſteemed by Alexander, that he forbad any body elſe to engrave his head; and Auguſtus's head, engraven by the latter, was found ſo beautiful, that the ſucceeding emperors choſe it for their ſeal.

All the polite arts having been buried under the ruins of the Roman empire, the art of *engraving* on ſtones ſhared the ſame fate. It was retrieved in Italy, at the beginning of the fifteenth century; when one John of Florence, and after him Dominic of Milan, performed works of this kind far from being contemptible.

From that time, ſuch ſculptures became common enough in Europe, and particularly in Germany, whence great numbers were ſent into other countries; but they came ſhort of the beauty of thoſe of the ancients, eſpecially thoſe on precious ſtones; for as to thoſe on cryſtal, the Germans, and after their example the French, &c. have ſucceeded well enough in them.

In this branch of *engraving* they make uſe either of the diamond or emery. The diamond, which is the hardeſt and moſt perfect of all precious ſtones, is only cut by itſelf, or with its own matter.

The firſt thing is to cement two rough diamonds to the ends of two ſticks, big enough to hold them ſteady by, in the hands; and to rub or grind them againſt each other, till they be brought to the figure deſired. The duſt, or powder, rubbed off, ſerves afterwards to poliſh them; which is performed with a kind of mill, that turns a wheel of lead, pewter, or copper.

The diamond is fixed in a braſs diſh, and thus applied to the wheel which is covered with a diamond duſt, mixed up with oil of olives; and when the diamond is to be cut facet-wiſe, they apply firſt one face, then another, to the wheel.

Rubies, ſapphires, and topazes, are cut and formed the ſame way, on a copper-wheel; and poliſhed with tripoli, diluted in water.

As to emeralds, hyacinths, amethyſts, garnets, agates, and other of the ſofter ſtones, they are cut on a leaden wheel, moiſtened with emery and water, and poliſhed with tripoli, on a pewter-wheel. Lapis lazuli, opal, &c. are poliſhed on a wooden-wheel.

To faſhion and engrave vaſes of agate, cryſtal, lapis lazuli, or the like, they have a kind of *lathe*, like that of the pewterers; excepting, that whereas the latter is to hold the veſſels, which are to be wrought with proper tools; the former generally holds the tools, which are turned by a wheel, and the veſſel is held to them to be cut and engraved, either in relievo, or otherwiſe; remembering from time to time to moiſten the tools with diamond-duſt and oil, or, at leaſt, with emery and water.

To engrave figures or devices on any of theſe ſtones, when poliſhed, ſuch as medals, or ſeals, &c. they uſe a little iron wheel, the two ends of whoſe axis are received within two pieces of iron placed upright, as in the turners lathe, and to be brought cloſer, or let farther aſunder, at pleaſure. At one end of one of the axes are fixed the proper tools, being kept tight by a ſcrew. Laſtly, the wheel is turned by the foot, and the ſtone applied by the hand to the tool; and thus ſhifted and conducted as occaſion requires.

The tools are generally of iron, ſometimes of braſs. As to their form, it is various, but is generally bears ſome reſemblance to chiſſels, gouges, &c. Some have ſmall round heads like buttons; others like ferrels, to take the pieces out; others flat, &c. Theſe tools are not applied directly againſt the ſtones, but, as it were, ſideways; thus wearing, and, as it were, grinding off the ſubſtance. And ſtill, whether it be figures, or letters, or characters, the manner of application is the ſame. The tools, as above obſerved, are to be frequently moiſtened with diamond duſt, and oil of olives. When the ſtone is engraven, they poliſh it on a wheel of bruſhes, made of hog's briſtles, with tripoli. For the larger, and leſs delicate works, they have copper, or pewter tools, on purpoſe to poliſh the ground, or plain parts, with tripoli, &c. which they apply after the ſame manner as thoſe wherewith the graving is performed.

ENGRAVING *in ſteel*, is chiefly employed in cutting punches, matrices, and dies, proper for ſtriking coins, medals, and counters.

The method of *engraving*, with the inſtruments, &c. are the ſame for coins, as for medals and counters: all the difference conſiſts in their greater, or leſs relievo; the relievo of coins being much leſs conſiderable than that of medals; and that of counters ſtill leſs than that of coins.

The engraver in ſteel uſually begins with punches, or pomelions, which are in relievo, and ſerve for making the creux, or cavities of the matrices, and dies; though ſometimes he begins immediately with the creux; but it is only when the intended work is to be cut very hollow. The firſt thing is to deſign his figures; then he

moulds them in white wax, of the size and depth required; and from this wax he graves his punch.

This punch is a piece of steel, or, at least, of iron and steel mixed; on which, before they temper, or harden it, the intended figure, whether a head, or a reverse, is cut, or carved, in relievo. The instruments used in this *graving* in relievo, which are much the same as those wherewith the finishing of the work in creux is effected, are of steel: the principal are gravers of divers kinds, chissels, flatters, &c. when the punch is finished, they give it a very high temper, that it may the better bear the blows of the hammer, wherewith it is struck, to give the impression to the matrice.

What they call *matrice*, or *matrix*, is a piece of good steel, of a cubic form, called also the *eye*, whereon the relievo of the punch is struck in creux: it is called *matrix*, because in the cavities, or indentures, thereof, the coins, or medals, seem formed, or generated, as animals are in the matrix of their mother. To soften this steel, that it may more easily take the impressions of the punch, they make it red-hot; and, after striking the punch thereon in this state, they proceed to touch up, or finish, the strokes and lines, where, because of their fineness, or the too great relievo, they are in any respect defective, with some of the tools above mentioned.

The figure thus finished, they proceed to engrave the rest of the medal, as the mouldings of the border, the engrailed ring, letters, &c. all which, particularly the letters, and graining, or engrailment, are performed with little steel punches, well tempered, and very sharp. Add, that as they sometimes make use of puncheons to engrave the creux of the matrix, so, on some occasions, they make use of the creux of the matrix to engrave the relievo of the punch.

To see and judge of the *engraving* in creux, divers means have been devised to take the impressions thereof, as the work proceeds; sometimes they make use of a composition of common wax, turpentine, and lamp-black; which, always retaining its softness, easily takes the impression of the part of the *graving* it is applied to; but this only serving to shew the work piece-meal, they have had recourse to other ways, to shew the whole figure. The first, by pouring melted lead on a piece of paper, and clapping the matrice thereon; the second, with melted sulphur, managed the same way; and the third, proper only where the *graving* is shallow, by laying a piece of soft paper on the *graving*, and over the paper a leaf of lead; when, giving two or three blows with a hammer on the lead, the paper takes the impression of the work.

When the matrix is quite finished, they temper it, rub it well with a pumice-stone, and clean out the stone again with a hair-brush; and, lastly, polish it with oil and emery: in this condition it is fit for the mill, to be used to strike coins, medals, &c.

After the like manner are the matrices for cutting of printing letters engraven. See *Letter* Foundery.

ENGRAVING *of seals, stamps, puncheons, marking irons, pilling irons*, and other matters, for goldsmiths, pewterers, bookbinders, &c. either in relievo, or indenture, is performed after the manner last described.

ENGRAVING *in wood*. See Cutting *in wood*.

ENGRAULIS, in *Ichthyology* a name given by some authors to the anchovy, called also, by some, lycostomus, and, by others, halecula. See Encrasicolus.

ENGROSSING, the writing of a deed over fair, and in proper legible characters. Among lawyers it more particularly means the copying of any writing fair upon parchment, or stamped paper. See Copy, Calligraphus, &c.

ENGROSSING, in *Commerce*, signifies the buying up any commodity in the gross, or forestalling the market. See Forestalling.

ENGUICHE, in *Heraldry*, is applied to the great mouth of a hunting horn, when it has a rim of a different colour from the horn itself.

ENGYSCOPE, from ἐγγὺς, *near*, and σκοπέω, *I observe*, a machine better known under the name of *microscope*. See Microscope.

ENGYTHECA, from ἐγγὺς, *near*, and θήκη, *repository*, in *Antiquity*, a cup-board, or place where cups and other vessels used to be laid.

ENHARMONIC, in *Music*, according to the division of the ancients, the last of the three *genera*, or kinds, of music.

The *enharmonic* genus is said to have been thus called, because of its superior excellence; though wherein that consists, says Mr. Malcolm, we do not see. It was by all acknowledged so difficult, that few could practise it. The several genera are divided into diastems upon which the differences depend. Those of the *enharmonic* are the *diesis*, and the *ditonum*; those of the *chromatic*, the *hemitonium*, and *trihemitonium*; and in the *diatonic*, the *hemitonium*, or *limma*, and the *tonus*.

But under these general names, which distinguish the *genera*, there are several different intervals, or ratios, which constitute the *species* or *colores generum*, which were the different species of *enharmonic*, chromatic, and diatonic.

According to some, the intervals, constituting the *enharmonic* genus, are the semitone minor, the *enharmonic* diesis, and the third major. Phil. Trans. N° 481. p. 272.

This is to be understood of what the *enharmonic* ought, accurately speaking, to be. Salinus has thus defined it, and others after him. This division is also approved of by Dr. Pepusch. The ancients do not agree in the numbers by which they express these divisions of the *enharmonic* genus; but the differences that occur are not sufficient to constitute any subordinate species of the *enharmonic*; and therefore they agree in not subdividing it. Phil. Trans. ibid. Vide Wallis, Appendix ad Ptolem. p. 165, 166.

ENHARMONICAL *diesis*. See Diesis.

ENHERITANCE. See Inheritance.

ENHYDRI, in *Natural History*, a genus of crystalline ferruginous bodies, formed into large, and, in great part, emmy cases, enclosing a small quantity of an aqueous fluid. Of this genus we have only two species. See *Tab. Fossils, class* 4.

Some of the ancients have supposed this stone so called, because its surface was always wet, as if by the effect of water coming from within. The word itself expresses this notion, as being compounded of ἐν and ὕδωρ. But Pliny tells us directly the contrary, that the water was contained within, and made to shew on the outside, and that the surface of the stone was white and smooth. From this it appears, that the *enhydros* of the Romans, or at least the kind known to Pliny, was not the ferruginous one, common in our time, but the flinty kind. Of these we have also some in England. They are, as he says, white and smooth on the surface, and are flints perfectly round, covered with a white crust, of the bigness of a large apple, and containing a quantity of water, lodged in their central cavity, and rattling in it on shaking.

ENHYDRIS, the ancient Greek name for the otter.

ENIF, a fixed star of the third magnitude, in Pegasus's mouth.

ENIGMA. See Ænigma.

ENIXUM *Sal*, among many of the *Chemists*, a neutral salt, neither acid nor alkaline, but participating of both.

Such are common salt, nitre, alum, vitriol, &c. Others apply it to peculiar salts, of this general kind. The *sal enixum* of Paracelsus is the caput mortuum of spirit of nitre, distilled in a retort with oil of vitriol: it is of a white colour, and pleasant acid taste. If this be dissolved in hot water, and crystallized, it will be a more pleasant medicine, possessing similar virtues with vitriolated tartar. It is diuretic, and may be given from a scruple to a dram, in broth, or water-gruel.

ENLARGE, in the *Manege*, is used for making a horse go large, that is, making him embrace more ground than he before covered. This is done when a horse works upon a round, or upon volts, and approaches too near the centre; so that it is desired he should gain more ground, or take a greater compass. To *enlarge* your horse, you should prick him with both heels, or aid him with the calves of your legs, and bear your hand outwards. If your horse narrows, he is enlarged by pricking him with the inner heel, and sustaining him with the outer leg, in order to press him forwards, and make his shoulders go. Upon such occasions the riding-masters cry only *large, large*. See In.

ENLARGING *statute*. See Statute.

ENMANCHE, in *Heraldry*, is when a chief has two lines drawn from the middle of the upper edge, to the sides, the depth of half the chief; the two lines including an obtuse angle, whose vertex is the centre of the top of the chief. See *Tab.* II. *Herald. fig.* 49.

The heralds conceive this, as bearing some resemblance to *sleeves*; whence the etymology of the word, from the French *manche, sleeve*. It differs from *chappe*, where the lines come from the top to the bottom of the chief.

ENNEACTIS, in *Natural History*, a name given by Linkius, to a sort of star-fish, of the more branched or aftophyte kind, which has only nine rays, where they first part from the body, but these divide into a vast number of others afterwards.

ENNEADECATERIS, in *Chronology*, a cycle, or period, of nineteen solar years.

The word is formed of ἐννέα, *nine*, δέκα, *ten*, and ἔτος, *year*. Such is the lunar cycle invented by Meton, at the end whereof the moon returns nearly to the same point from which it departed. Whence the Jews, Athenians, and other

other nations, who were disposed to accommodate the lunar months to the solar years, made use of the *enneadecaeteris*; allowing to seven of the years thirteen months apiece, and to the rest twelve. See CYCLE, and EMBOLISMIC.

ENNEADECAETERIS, *the Jewish*, is properly a cycle of 19 lunar years, beginning from *mund tehu*, and returning again and again; wherein of every 3d, 6th, 8th, 11th, 14th, 17th, and 19th, are embolismic, or of 383 days 21 hours apiece; the rest common, or of 354 days 8 hours apiece. See YEAR.—Consequently, the Jewish *enneadecaeteris* is 6939 days 18 hours.

ENNEAGON, in *Geometry*, a figure of nine angles, and nine sides.

The word is formed of *ennea*, *nine*, and *gonia*, *angle*.

ENNEAGON, in *Fortification*, denotes a place with nine bastions. See FORTIFIED *Place*.

ENNEAHEDRIA, in *Natural History*, the name of a genus of spars.

The word is derived from the Greek *ennea*, *nine*, and *hedra*, *a side*.

The bodies of this genus are *spars*, composed of nine planes, in a trigonal column, terminated at each end by a trigonal pyramid. Of this genus there are four known species. Hill's Hist. of Foss. p. 608.

ENNEANDRIA, in *Botany*, the ninth class of plants, with hermaphrodite flowers, and nine stamina, or male parts, in each.

The word is derived from the Greek *ennea*, *nine*, and *aner*, *male*.

This class comprehends three orders; viz. the *monogynia*, having one style, of which there are four genera: the *trigynia*, having three styles including one genus; and *hexagynia*, having six styles, and containing one genus.

The plants of this class are the bay-tree, rhubarb, &c.

ENNEATICAL *days* are every ninth day of a sickness; which, some imagine, naturally occasion a great alteration, either for the better, or worse.

ENNEATICAL *years* are every ninth year of a man's life. See CLIMACTERIC.

ENNEEMIMERIS is one kind of the *cæsura* of a Latin verse, where, after the fourth foot, there is an odd syllable ending a word, which helps to make the next foot with the following word; as in this instance,

Ille latus niveum molli fultus hyacintho.

where all the four kinds of the *cæsura* occur.

ENNEOPHTHALMUS, from *ennea*, *nine*, and *ophthalmos*, *eye*, in *Ichthyology*, a name given, by some, to the lamprey.

ENNERIS, in the *Ancient Ship-Building*, a name given to those GALLEYS, or vessels, which had nine tires of rowers. These were of a very considerable size; though Meibom has found so convenient a method of placing the rowers, that he has taken off very much from that immense height others supposed they had above the water. We read of the tessaracontes, and other amazing vessels of this fabric; that of Philopater having forty rows of oars, and that of Ptolemy Philadelphus thirty; and some others which are spoken of, twenty. It has been disputed by many, whether such large vessels as those were ever actually built, or used; but Meibom gives great reason to believe, that they really were, though he, at the same time, alleges against Salmasius, and the more sanguine admirers of the works of the ancients, that very few vessels were built larger than these *enneres*, or nine-tired ones, and proves it from Livy and Plutarch, and from Polybius. We are apt to admire, in many cases, what we ought also to imitate, but never attempt it. This is the case in these galleys; and Meibom, who has given the rules of this ancient naval architecture, is of opinion, that by imitating it at present, modern galleys and galleasses might be built much more conveniently both for strength and celerity, and also at less expence than they are at present. Meibom. de Triem.

The modern form is indeed allowed to be better than theirs, but if, in the structure, the proportion of the long ships of the ancients were observed, they might be greatly improved; in the modern way of five men sitting at one oar in the galleasses, much strength is wasted to no purpose, because they sit too near to the fulcrum, or stay, whereas a small number of rowers, at a greater distance from the stay, would give more strength, and throw the vessel along much more swiftly, and would require less charge. Galleys of this sort, thus managed at a small expence, would be found of great use in the larger rivers, and in the shallow seas, and therefore convenient for the Baltic, the Britannic, and the Mediterranean seas, and would be the most useful of all vessels for transporting great numbers of forces.

ENOLMIS, ἐνόλμις, in *Antiquity*, a designation given to Apollo's priestess at Delphi, because she sat on the tripod which was called *olmos*, ὄλμος. Hence also Apollo is called *Enolmus*, Ἐνόλμιος. Pott. Archæol. Græc. lib. ii. cap. 9. tom. i. p. 275.

ENORAINE, in the *Manege*, a wither-wrung horse, or one that is spoiled in the withers. The word is obsolete.

ENORCHIS, in *Natural History*, the name given, by many authors, to that species of *aetites*, or eagle-stone, in which the callosus, or internal nucleus, is not loose, so as to rattle in it when shaken, but remains fixed to one side. The Germans call this *hodenstein*. The outer crust is usually of a whitish colour, and the internal nucleus is yellowish or brownish, and it is usually of the size of a pigeon's egg, and of the shape of the human testicle, whence the name.

ENORMOUS, something excessive, or monstrous, especially in bulk. The COLOSSUS of Rhodes was of an *enormous* stature.

The word is formed of the privative *e*, and *norma*, *rule*, q. d. *void of, or contrary to, rule or measure*; *contra normam*. In the corrupt ages of Latinity, they used *enormis*, and *enormia*.

In the French *jurisprudence*, *lesion enormie*, *enormous damage*, is that which exceeds half the value of the *thing sold*.

ENQUEST, or INQUEST, in *Law*, denotes an inquisition of a jury by hearing of witnesses.

This is the most usual manner of trial, in all causes, both civil and criminal, within this realm. In civil causes, after proof *is made*, on either side, of so much as each party thinks good for himself; if the doubt be in the effect, it is referred to the discretion of twelve indifferent men, impanelled by the sheriff for that purpose; and as they bring in their verdict, so judgment passeth: for the judge saith, *the jury findeth the fact thus*. For the *enquest* in criminal causes, see JURY.

ENRICHED *column*. See COLUMN.

ENRICHING *plants*, a term used, by the English farmers, to express such plants as are found to do good to land, rather than to exhaust it, and in consequence of which the same piece of land will produce a good crop of corn, though it would without the assistance of their having been planted on it, have yielded a very poor one. The mystery of this difference between plants, some of which are found to burn up, that is, impoverish lands, while others enrich it, and leave it fitter for succeeding crops than they found it, is explained by Mr Tull. This author having observed, that breaking the earth, by digging, or horse-hoeing, between the plants, gave them great increase, found that it was this practice that enriched the earth; and that, while corn and such plants as stand close, and cannot be hoed between, impoverish the ground, and suffer no means of *enriching* it again to be used, there were some other things, the crops of which being planted thinner, gave room to the earth to be ploughed, dug, or hoed between, and that these were the plants which were called the *enriching* kind by the farmers; and the whole secret lay in this, that the hoeing, ploughing, or otherways breaking the earth between them, in order to kill the weeds, enriched the ground greatly more, in proportion, than these plants exhausted it; and the consequence was, that though they had thriven very well, yet the earth was left richer than before, notwithstanding all that they had imbibed from it. Tull's Horsehoeing husbandry, p. 37.

On this observation, this excellent author seems to have founded the system of what he calls horsehoeing husbandry, concerning which he has written a large and useful treatise. He found that this stirring up of the earth enriched it so greatly, that, where it was used in a proper manner, the kind of plant need not be changed, but that the same earth would yield a successive series of crops of the same plant, and that even without dunging, or ever lying fallow, and every crop, for a long time, would be better than the former ones. The method of sowing, to this purpose, is not by scattering the corn with the hand, but sowing it in rows, and leaving large intervals between, the naked earth of which might be turned up by the hoe. See ALLEY and HOEING.

ENROLLMENT. See INROLLMENT.

Clerk of the ENROLLMENT *of fines*. See CLERK *of the Inrollments*.

ENS, ENTITY, *Being*, in *Metaphysics*, is applied, in a general sense, to every thing which the mind any way apprehends, and whereof it affirms, denies, proves, or disproves, any thing. This other philosophers call *cogitable*, and *intelligible*; and the logicians, *thema*.

ENS, in a less general sense, signifies something that is, or exists, some way farther than by being conceived, or being capable of being conceived, in the mind. This is particularly called *ens positivum*, or *reale*; positive, or real, being. In opposition to which stands *ens ens*.

ENS, in its proper, or restrained sense, is that to which there are real attributes belonging; or that which has a reality, not only out of the intellect, but in itself. The

is what is properly meant by *res*, *thing*; and what we otherwiſe call *ens reale*, and alſo *ſubſiſtance*.

ENS *rationis*, is that which depends wholly on the mind, or which exiſts only in the imagination: of which they diſtinguiſh three kinds: *ens rationis objectivum*, which is done or produced by the mind, as knowledge; *ens rationis ſubjectivum*, which is received into the mind, as ſcience; and *ens rationis objectivum*, which is repreſented by the mind, as a chimæra, a golden mountain, or the like. Which laſt, if it have no other manner of being, *i. e.* if it be repreſented ſo as it does not, or cannot be, is what we moſt properly call, *ens rationis*. The generality of ſchool philoſophers, and the Peripatetics among the reſt, aſſert, that there are of theſe *entia rationis objectiva*. Others deny there are, or can be, any ſuch things.

ENS, or ENS *primum*, in *Chemiſtry*, denotes the moſt efficacious part of any natural mixt body, whether animal, vegetable, or foſſil, wherein all the qualities or virtues of the ingredients of the mixt are comprehended in a ſmall compaſs.

Paracelſus pretends to have been able to ſeparate the *ens primum* from bodies, and with it to effect prodigious things towards the renovation and reſtoration of youth; but his proceſſes are ſo obſcurely delivered, that no body has been induced to try them.

Mr. Boyle gives us a proceſs from M. le Febure, whereby the *ens primum*, or eſſence of baum, is eaſily obtained; he adds, that the effects of an *ens* of baum, thus drawn, are no ways inferior to thoſe of Paracelſus; and inſtances in a ſpecial friend of his, upon whoſe taking it only for a fortnight, the nails of his hands and feet fell off, and were ſucceeded by a ſet of new ones; which convinced him ſo far of its efficacy, that he left off taking it himſelf; but giving ſome of it to an old woman of ſeventy years of age, who ſerved in the houſe, it produced the menſes again; and that ſo copiouſly, as wonderfully to ſtartle the woman.

Upon giving a little of it to an old hen, her feathers began to moult on the firſt day, and ſhe became ſtark-naked; but before a fortnight was over, ſhe had others in their room, which were fairer, and better coloured than the former.

The relation is odd enough; yet, conſidering the authority from which we have it, and how eaſily the thing is tried, it is ſurpriſing no body has yet attempted to proſecute it. The proceſs is this:

Having gathered, *e. gr.* ſome baum, or other proper plant, at the proper ſeaſon and time, beat it into a pulp in a marble mortar; and, putting it into a bolt-head hermetically ſealed, digeſt it forty days on a dung-hill, or other analogous heat: this done, take out the matter, which will now be more liquid than before; and ſeparating from it the dregs or groſſer parts, digeſt it anew in a gentle bath, that the remaining groſſer parts may alſo ſubſide; filtrate it, and add to it the fixed ſalt drawn from the former dregs, dried and calcined; to the liquor thus prepared, add equal parts of the liquor of good ſea-ſalt, well purified and melted, and then let it run *per deliquium*; laſtly, ſeal up the mixture in a bolt-head, and expoſe it to the ſun ſix weeks longer; at the end of which term, the *ens primum* of the plant will be found ſwimming on the liquor, in a liquid, tranſparent form, ſometimes of a green, and ſometimes a reddiſh colour, according to the plant uſed.

ENS *primum ſalium*, a name given by Paracelſus to a preparation of ſea-ſalt, which he calls alſo a perpetual oil, and SAL *circulatum*, which ſee.

ENS *Veneris*, or *flower of Venus*, a chemical preparation from vitriol, firſt publiſhed by Mr. Boyle, held as a ſpecifick in the rickets, and much commended in nervous caſes, obſtinate cachexies, loſs of appetite, and obſtructions of all kinds.

It is prepared by ſubliming equal parts of the powder of Cyprus vitriol (calcined till it is of a black colour) and of ſal ammoniac, into the form of yellow flowers. It has its name from the particles of Venus, copper, imparted to it by the vitriol.

ENS *martis*, is the flower of iron ſublimed with the ſame ſalt.

ENSAL, in the *Materia Medica*, a name uſed by ſome authors for the common ſmall cardamom of the ſhops.

ENSCONCED, in the *Military Art*. See INSCONCED.

ENSEELED, in *Falconry*, a term uſed for a hawk which has a thread drawn through her upper eyelids, and made faſt under her beak, to obſcure her ſight.

ENSEMBLE, a French term, ſometimes uſed in our language, literally ſignifying *together*, or *one with another*; being formed from the Latin, *in*, and *ſimul*.

In *Architecture*, we ſay, the *enſemble*, or *tout enſemble* of a building; meaning the work or compoſition, conſidered together, and not in parts; and ſometimes alſo the relative proportion of the parts to the whole. All thoſe pieces of building make a fine *enſemble*.

To judge well of a ſtatue, or other work of ſculpture, one muſt firſt examine whether the *enſemble* be good.

The *tout enſemble* of a painting, is that harmony which reſults from the diſtribution of the ſeveral objects or figures whereof the whole is compoſed. This picture is good, taking the parts ſeparately; but the *tout enſemble* is bad.

ENSIFORM *Leaf*, in *Botany*. See LEAF.

ENSIFORMIS, of *enſis*, *ſword*, and *forma*, *ſhape*, *Cartilago*. See XIPHOIDES.

ENSIGN, in the *Military Art*, a banner or COLOURS, under which the ſoldiers are ranged, according to the different companies or parties to which they belong. When a battalion is encamped, they are placed in its front; but in garriſon they are lodged with the commanding officer. There is a ſmaller ſort, called camp-colours, placed on the right and left of the parade of a regiment when in the field. See FLAG and STANDARD.

The Turkiſh *enſigns* are horſes tails; the number of which diſtinguiſhes the rank of their commanders; the ſultan has ſeven, the grand vizier only three, &c. Thoſe of the Europeans are pieces of taffety, with divers figures, colours, arms, and devices, thereon. Xenophon tells us, that the *enſign* borne by the Perſians was a golden eagle on a white flag; the Corinthians bore the winged horſe, or Pegaſus; the Athenians, an owl; the Meſſenians, the Greek letter M; the Lacedæmonians, the A.

The Romans had a great diverſity of *enſigns*; the wolf, minotaur, horſe, boar, and at length the EAGLE. See SIGNA.

A military *enſign*, on a medal of a Roman colony, denotes it a colony peopled with old ſoldiers.

ENSIGN, in a *Ship*, are thoſe colours which are hoiſted on a long pole erected over the poop, and called the *enſign-ſtaff*. There are few ſhips, whether men of war or merchants, but have their *enſigns*. Their chief uſe is, that when any ſtrange ſhips meet at ſea, or make into any harbour, by hearing out the colours in the poop, that is, putting theſe *enſigns* abroad, they diſcover of what part and country they are, and ſerve to characteriſe the different ſquadrons of the navy. Thus, the Britiſh heave out their colours with a double croſs, *viz.* that of St. George and St. Andrew, formed into an union, upon a field which is either red, white, or blue; and ſo all other countries with ſome particular diſtinction, whereby they may be known. The *enſigns* ſerve alſo for many other uſes. See FLAG.

ENSIGN, is alſo uſed for an officer in the infantry, who bears the *enſign* or colours; by the Latins called *ſignifer* and *vexillifer*.

He has the charge of the *enſign* in battle; and, if he be killed, the captain is to take it in his ſtead. The *enſign* is the loweſt commiſſioned officer in a company of foot, under the command of the lieutenant; and, in his abſence, ſupplies his poſt. In cavalry, the *enſign* is termed a cornet. See CORNET.

ENSTASIS, *Ἔνστασις*, of ἐν and ἵστημι, *ſtatuo*, in *Logic*, a manner of replying to an opponent, either by confuting his argument, or denying the juſtneſs of his concluſion. Voſſ. Rhet. lib. iii. p. 380.

ENSTASIS, in *Medicine*, a term uſed to expreſs the ingreſs of moleculæ into the vacuity of the pores which obſtruct them, and thereby cauſe diſeaſes. It is a word familiar with Eraſiſtratus and Aſclepiades, who was a follower of Democritus, and taught that moſt diſeaſes were cauſed by ſuch an ingreſs of matter into the pores. Thus Aſclepiades deſined a phrenſy to be ſuch an *enſtaſis* in the membranes of the brain. Plutarch, in his Precepts of Health, alſo mentions this *enſtaſis*: and Galen and Caſſius, who is ſuppoſed to have been of the ſect of the Rationaliſts, expreſſes the ſame ſenſe by the ſame word.

ENTABLATURE, in *Architecture*, is that part of an order of column which is over the capital; comprehending the ARCHITRAVE, FRIZE, and CORNICHE.

The word ſeems formed of *tabulatum*, or *intabulamentum*. The *entablature* is alſo called the *traboation*, and by Vitruvius and Vignola, *ornament*. It is different in the different orders: indeed, it conſiſts of the three grand parts or diviſions above mentioned, in all; but thoſe parts conſiſt of a greater or leſs number of particular members or ſubdiviſions, as the orders are more or leſs rich.

Vignola makes the *entablature* a quarter of the height of the whole column, in all the orders.

In the Tuſcan and Doric, the architrave, frize, and corniſh, are all of the ſame height; in the Ionic, Corinthian, and Compoſite, the whole *entablature* being fifteen parts, five of them are allowed for the architrave, four for the frize, and ſix for the corniche. See IONIC, CORINTHIAN, &c. and COLUMN.

ENTABLATURE, or ENTABLAMENT, is ſometimes alſo uſed for the laſt row of ſtones on the top of the wall of a building, whereon the timber and covering reſt.

As this is frequently made to project beyond the naked

of the wall to carry off the rain, some authors call it in Latin, *stillicidium*, or *drip*. Such an *entablature* does not stand out far enough; it lets the water fall on the foot of the wall.

ENTABLER, in the *Manege*, is faid of a horfe whofe croupe goes before his fhoulders, in working upon volts; for, in the regular manege, one half of the fhoulders ought to go before the croupe. Thus we fay, your horfe *entables*; for, in working to the right, he has an inclination to throw himfelf upon the right hand; which fault you may prevent, by taking hold of the right rein, keeping your right leg near, and removing your left leg as far as the horfe's fhoulder. A horfe cannot commit this fault without committing that called ACULER; but *aculer* may be without *entabler*.

ENTAIL, in *Law*, fignifies FEE TAIL, or *fee intailed*, that is, abridged, curtailed, or limited to certain conditions. For the docking of an *entail*, fee DOCKING and RECOVERY.

ENTALI, in the *Materia Medica*, a name given by fome authors to foffile alum.

ENTALIUM, the *pipe-fhell*, in the *Materia Medica*, a fhell of the fame genus with the *dentalia*, being a fpecies of the *tubuli marini*. It is frequent in the Eaft Indies, and fometimes is found on our own fhores. The virtues aferibed to it are the fame with thofe of the *dentalium*; but neither of them have any title to more than thofe of all alkaline abforbents, like the other teftaceous powders.

ENTASIS, *diftenfion*, from εν and τεινω, *I ftretch*, a word ufed in various fenfes, by different authors in *Medicine*, but by moft applied to the parts of generation; and hence *entatica* were medicines, in whatever form, meant as provocatives.

ENTE', in *Heraldry*, literally implies *engrafted*, and is ufed by foreign heralds to expreſs a method of marſhalling, little known among us: yet we have an inſtance of it in the fourth grand quarter of his majeſty's royal enſign, whofe blazon is Brunſwick and Lunenburgh, impaled with ancient Saxony, *enté in pointe*.

ENTELECHIA, εντελεχεια, *perfect*, a Greek term, by which Ariſtotle defines the ſoul; and which, not occurring in any other author, has given the critics and philoſophers infinite perplexity to diſcover its true meaning. See SOUL.

Hermolaus Barbarus is even ſaid to have conſulted the devil about it; after which, in his paraphraſe on Themiſtius, whether from the devil or himſelf, we know not, he renders it by *perfectibabia*, which is not a whit the clearer.

Cicero, whoſe interpretation ſhould be preferable to that of any modern, defines *entelechia* (Tuſc. Queſt. lib. i. cap. 11.) to be, *a certain, continued, and perpetual motion*; whence it ſhould ſeem, that Ariſtotle took the ſoul for the mode of the body; a *continuous motion* being, doubtleſs, a mode of body.

The common Peripatetics hold *entelechia* to ſignify *act*, and under it ſuppoſe the form of the compound or animal to be underſtood.

Laſtly, others, and thoſe the lateſt Peripatetics, agree, that the *act*, or *entelechia*, whereby Ariſtotle meant to expreſs the nature of the ſoul, is either ſome mode of the body, as motion, or it is nothing.

ENTENDEMENT, in *Law*. See INTENDMENT.

To ENTER *a Hawk*, among *Sportſmen*, is uſed of a hawk when ſhe begins to kill.

To ENTER *a Hound*. See ENTRANCE *of hounds*.

ENTERADENES, of εντερον, *inteſtine*, and αδην, *gland*, in *Anatomy*, a name by which many authors have called the inteſtinal glands.

ENTERENCHYTÆ, of εντερον, *the viſcera*, and εγχυω, *I infuſe*, in *Medicine*, a name given by authors to the ſeveral inſtruments contrived for throwing clyſters into the bowels; ſuch as the bladder and pipe, the ſyringe, and the like, for liquid clyſters; and the box with the double pipe for conveying the ſmoak of tobacco. See CLYSTER, and FUMIGATION.

ENTERFERING, in the *Manege*. See CUTTING.

ENTERMEW. See FALCON.

ENTEROCELE, in *Medicine*, a rupture, or deſcent of the inteſtines.

The word is formed of εντερον, *inteſtine*, and κηλη, *tumor*.

The *enterocele* is a kind of hernia, or rupture, wherein the inteſtines, and particularly the ilium, fall either into the groin or the ſcrotum. See HERNIA.

There are two kinds of *enterocele*; the *perfect*, which happens when the inteſtine falls into the ſcrotum; and the *imperfect*, when it only falls into the groin.

The next cauſe of the *enterocele* is, the relaxation, or extenſion of the lower part of the peritonæum, wherein the inteſtines are contained. The remote cauſes are, great lifts, too violent exerciſes, great cought, frequent vomiting, much crying, &c. whence it is that children are much ſubject to it. The remedy is chiefly by external applications, as truſſes and bolſters.

ENTERO EPIPLOCELE, a kind of rupture, wherein the inteſtines, and *epiploon* or caul, fall together into the *ſcrotum*. See HERNIA. The cauſes are the ſame as thoſe of the ENTEROCELE.

ENTERO-EPIPLOMPHALUS, a kind of exomphalus, wherein the inteſtines, and epiploon or caul, bunch out at the navel.

The word is compoſed of εντερον, *inteſtine*, επιπλοον, *caul*, and ομφαλος, *umbilicus*, *navel*.

ENTERO-HYDROMPHALUS, in *Medicine*, a kind of exomphalus, wherein, beſide a diſplacing and bunching out of the inteſtine, there is a quantity of watery humours collected along with it.

The word is formed of the Greek, εντερον, *inteſtine*, υδωρ, *water*, and ομφαλος, *navel*.

ENTEROLOGY, (from εντερον, *inteſtinum*, *a gut*, and λογος, *ſermo*, *diſcourſe*) is properly a treatiſe of the bowels. Though the word is generally underſtood to include the contents of three cavities, head, breaſt, and all the viſcera or belly.

ENTEROMPHALUS, εντερομφαλος, in *Medicine*, a kind of exomphalus, wherein the inteſtines, being fallen out of their place, occaſion a tumor in the navel. See EXOMPHALUS and HERNIA.

The word is formed of the Greek, εντερον, *inteſtine*, and ομφαλος, *umbilicus*.

ENTERORAPHE, of εντερον and ραφη, *ſuture*, in *Surgery*, a name given to the ſutures of the inteſtines.

To ENTERPEN, in *Falconry*, is a term applied to a hawk, when her feathers are wrapped up, matted or entangled.

ENTERPLEADER, in *Law*, the diſcuſſing or trying of a point incidentally falling out before the principal cauſe can be determined.

Thus, two perſons being found heirs to land by two ſeveral offices in one county, the king is brought in doubt to which of them livery ought to be made. Before livery, therefore, they muſt *enterplead*; that is formally try between themſelves which is the right heir.

ENTERPRISE, denotes an undertaking attended with ſome difficulty and danger: in the *Military Art*, this kind of ſervice is aſſigned to the light-infantry, light-horſe, and huſſars.

ENTERRMENT, or INTERRMENT. See INTERRMENT.

ENTERSOLE. See MEZANINE.

ENTERTAINMENTS, *epulæ*, among the ancients, were of various kinds, as 1. *Funeral entertainments*, *epulæ funebres*. 2. *Entertainments* given by the huſband on bringing home his wife, called *epulæ genitales*. 3. Thoſe beſtowed on the ſoldiers, called *epulæ militares*, which was done before or after an engagement, or on occaſion of proclaiming the general *imperator*. 4. *Birth-day entertainments*, *epulæ natalitiæ*.

There were many other kinds, denominated either from the place where, the perſons by whom, or the occaſion for which they were given.

ENTERVIEW, in *Falconry*, a term uſed for the ſecond year of a hawk's age.

ENTHALIUM, in *Natural Hiſtory*, a name given by ſome to a ſpecies of the *tubuli marini*, more uſually known by the name of *penicillum nettunum*, and *pinceau de mer*. See PENICILLI *Marini*.

ENTHEMATA, from εντιθημι, *I put in*, in *Medicine*, a word uſed to expreſs ſuch medicines as were immediately put into large freſh wounds to ſtop the hæmorrhage, and prevent inflammation, or other bad conſequences.

ENTHETOS, from εντιθημι, in the writings of the old *Phyſicians*, a name given to certain applications intended to be thruſt up the noſtrils to ſtop hæmorrhages.

ENTHUSIASM, ενθουσιασμος, a poetic, or prophetic rage or fury, which tranſports the mind, inflames and raiſes the imagination, and makes it conceive and expreſs things extraordinary and ſurprizing.

The word is derived from the Greek, ενθεος, or ενθους, a man animated in an extraordinary manner with the ſpirit of God; in whom God is, or whom God animates. Whence the verb ενθουζαζω, or ενθουσαω, and the noun ενθουσιασμος, *enthuſiaſm*: and ενθουσαστης, *enthuſiaſt*, a perſon ſubject to ſuch tranſports.

M. de Piles defines *enthuſiaſm* to be a tranſport of the mind, whereby it is led to think and imagine things in a ſublime, ſurpriſing, yet probable manner.

The ſublime he thinks a neceſſary ingredient in the definition, as being the proper effect and production of *enthuſiaſm*.

This is the *enthuſiaſm* felt in poetry, oratory, muſic, painting, ſculpture, &c. but this *enthuſiaſm* which belongs to the works of art, is very different from that attributed to the ſibyls and prieſteſſes of the oracles, and heathen

heathen gods, which was little elſe but fanaticiſm, and conſiſted principally in grimace, and contorſions of the body. See ORACLE and PYTHIAN.

There is a degree of aſſent, ſays Mr. Locke, which, with ſome men, has the ſame authority as either faith or reaſon; and that is *enthuſiaſm*, which, laying by reaſon, would ſet up revelation without it; whereby, in effect, it takes away both reaſon and revelation, and ſubſtitutes in the room of it the ungrounded fancies of a man's own brain, and aſſumes them for a foundation, both of opinion and conduct.

Immediate revelation being a much eaſier way for men to eſtabliſh their opinions, and regulate their conduct by than the tedious labour of ſtrict reaſoning; it is no wonder, that ſome have been very apt to pretend to it; eſpecially in ſuch of their actions and opinions as they cannot account for by the ordinary methods of knowledge and principles of reaſon. Hence we ſee, that in all ages men in whom melancholy has mixed with devotion, or whoſe conceit of themſelves has raiſed them into an opinion of a greater familiarity with God than is allowed others, have often flattered themſelves with the perſuaſion of an immediate intercourſe with the Deity, and frequent communications with the Divine ſpirit.

Their minds being thus prepared, whatever groundleſs opinion comes to ſtrike itſelf ſtrongly upon their fancies, is an illumination from the ſpirit of God; and, whatſoever odd action they find in themſelves an inclination to do, that impulſe is concluded to be a call or direction from heaven, and muſt be obeyed.

This we take to be properly *enthuſiaſm*; which, though riſing from the conceit of a warm or over-weening brain, works where it once gets footing, more powerfully on the perſuaſions and actions of men than either reaſon or revelation, or both together; men being moſt forwardly obedient to the impulſes they receive from themſelves.

When men are once got into this way of immediate revelation, or illumination without ſearch, and certainty without proof, reaſon is loſt upon them; they are above it; they ſee the light infuſed into their underſtanding, and they cannot be miſtaken: like the light of bright ſun-ſhine, it ſhews itſelf, and needs no other proof but its own evidence; they feel the hand of God moving them within, and the impulſes of the ſpirit, and cannot be miſtaken in what they feel. But, of this ſeeing and feeling, is it a perception of an inclination to do ſomething, or of the Spirit of God moving that inclination? theſe are two very different perceptions, and ſhould be carefully diſtinguiſhed.

If they know the thing to be a truth, they muſt do it, either by its own ſelf-evidence, or by the rational proofs that make it out to be ſo; if they know it to be a truth, either of theſe two ways, they in vain ſuppoſe it to be a revelation; for thus, all truths, of what kind ſoever, which men uninſpired are enlightened with, come into their minds. If they ſay, they know it to be true, becauſe it is a revelation from God, the reaſon is good; but then it will be demanded, how they know it to be a revelation from God? if they ſay, by the light it brings with it, they ſhould conſider, whether this be ſaying any more than that it is a revelation, becauſe they believe it to be true; for all the light they ſpeak of is but a ſtrong perſuaſion of their own minds that it is a truth, which is a very unſafe ground to proceed on, either in our tenets or actions. True light in the mind, is nothing elſe but the evidence of the truth of any propoſition; and if it be not ſelf-evident, all the light it can have is from the clearneſs of thoſe proofs upon which it is received. See EVIDENCE.

God, when he makes the prophet, doth not unmake the man; he leaves his faculties in their natural ſtate, to enable him to judge of his inſpirations, whether they be of divine original or not. If he would have us aſſent to the truth of any propoſition, he either evidences that truth by the uſual methods of natural reaſon, or elſe makes it known to be a truth which he would have us aſſent to by his authority; and convinces us that it is from him, by ſome marks which reaſon cannot be miſtaken in. Eſſay on Hum. Underſt. book iv. chap. 19.

The holy men of old, who had revelations from God, had ſomething elſe beſides internal light, of aſſurance in their own minds, to teſtify to them that it was from God; they had outward ſigns to convince them of the Author of thoſe revelations: and when they were to convince others, they had a power given them to juſtify the truth of their commiſſion from heaven; and, by viſible ſigns, to aſſert the Divine authority of the meſſage they were ſent with. Moſes ſaw the buſh burning without being conſumed, and heard a voice out of it. God, by another miracle, of his rod turned into a ſerpent, aſſured him likewiſe of a power to teſtify his miſſion, by the ſame miracle repeated before thoſe to whom he was ſent.

Devotion, undirected and unreſtrained by reaſon, degenerates into *enthuſiaſm*, or a religious phrenſy, founded in an apprehenſion of a preſent Divine energy on the mind, to which all its powers are ſuppoſed to be ſubject, and by which a perſon is carried on, without attention to any thing elſe as his guide, and producing not only great perturbation of mind, but moſt amazing agitations of body. Many inſtances of this kind occur, both in ancient and modern times, to the diſgrace and injury of rational religion.

ENTHUSIAST, *Ἐνθουσιαστὴς*, a perſon poſſeſſed with *enthuſiaſm*. See ENTHUSIASM. FANATIC, &c.

The word is uſually underſtood in an ill ſenſe. It was applied by the ancients to a ſect of heretics, called alſo *Meſſalians* and *Euchites*; who, as Theodoret expreſſes it, were denominated *enthuſiaſts*, becauſe, being poſſeſſed by the devil, they believed themſelves divinely inſpired. See MASSALIANS and EUCHITES.

Among us, *enthuſiaſt* is ſometimes of like import with *fanatic*, and is applied to the Quakers and ancient Anabaptiſts, and modern prophets, from their pretences to extraordinary lights, revelations, viſions, impulſes, &c. from heaven.

ENTHYMEME, in *Logic* and *Rhetoric*, an argument conſiſting only of two propoſitions, an antecedent, and a conſequent deduced from it.

The word is Greek, *ἐνθύμημα*, formed of the verb *ἐνθυμεῖσθαι*, to think, conceive, a compound of *ἐν* and *θυμὸς*, *mind*.

Ariſtotle calls it the *rhetorical* or *probable argument*; the ſchools, the *imperfect ſyllogiſm*, in contradiſtinction to the perfect, which conſiſts of three propoſitions, and is called the *dialectical argument*.

It muſt be obſerved, however, that the *enthymeme* is really a perfect ſyllogiſm in the mind, and only imperfect in the expreſſion, becauſe one of the premiſes is ſuppreſſed, as being ſufficiently clear and obvious, and eaſily ſupplied by the underſtanding of thoſe with whom we diſcourſe. Thus, in every right-lined triangle, the three angles are equal to two right ones; and conſequently, they are ſo in an iſoſceles triangle, is an *enthymeme*; the propoſition, that an iſoſceles triangle is a right-lined triangle being omitted, as being ſufficiently known and granted.

The *enthymeme* is the moſt ſimple and elegant of all argumentations; being what a man, in arguing cloſely, commonly makes, without attending at all to the form. Thus, that verſe remaining of Ovid's tragedy, intitled, Medea, contains an *enthymeme*: *Seruare potui, perdere an poſſim rogas: I was able to ſave you; conſequently, to have deſtroyed you.* All the beauty would have been loſt, had all the propoſitions been expreſſed; the mind is diſpleaſed with a rehearſal of what is no ways neceſſary.

Sometimes, alſo, the two propoſitions of an *enthymeme* are both included in a ſingle propoſition, which Ariſtotle calls an *enthymematical ſentence*, and gives this inſtance thereof: *Mortal, do not bear an immortal hatred.* The whole *enthymeme* would be, *Thou art mortal; let not, therefore, thy hatred be immortal.*

ENTIER, in the *Manage*, is uſed for a ſort of reſty horſe, that refuſes to turn, and is ſo far from following or obſerving the hand, that he reſiſts it. If your horſe is *entier*, and refuſes to turn to what hand you will, provided he flies, or parts from the heels, you have a remedy, by putting the Newcaſtle on him; that is a caveſſon, made after the duke of Newcaſtle's way.

The word is French, and is alſo uſed among them to denote a ſtone-horſe.

ENTIERTIE, from the French, *entier*, is uſed in our *Law-books*, in contradiſtinction to *moiety*, and denotes the whole. Thus a bond, damages, &c. are ſaid to be entire, when they cannot be divided or appoſtioned.

ENTIRE *Tenancy*, in *Law*, is contradiſtinguiſhed to *ſeveral tenancy*, and ſignifies a ſole poſſeſſion in one man; whereas the other denotes a joint, or common one, in ſeveral. See TENANT and JOINT-TENANT.

ENTIRE *arms*. See ARMS.

ENTITATIVELY, ENTITATIVE, implies an abſtraction, or ſeparation, of all the circumſtances, from a thing under conſideration.

Thus, a thing is ſaid to be taken or conſidered *entitatively*, or *ſecundum entitatem*, when conſidered nakedly and preciſely, according to what it is in itſelf, without any thing extrinſic. E. gr. Peter *entitatively* taken, is Peter, as a thing, a ſubſtance, a man, &c. without any regard to his being a lord, a huſband, learned, &c.

ENTITY, in the *Scholaſtic philoſophy*, a phyſical ens, or being, conſidered according to what it is in its natural capacity.

Some dealers in diſtinctions give us ſeveral kinds of *entity*.

Or, *entity* denotes the actual eſſence or exiſtence of any thinking thing. See ENS.

ENTORSES, *in the Manege.* See PASTERN.

ENTOYER, or ENTOISE, in *Heraldry*, is uſed to expreſs a bordure, charged entirely with things without life. See BORDURE.

ENTRAILS, the inteſtines or guts of an animal. See INTESTINES.

Menage derives the word from the barbarous Latin, *intralia*, formed of the Greek, *ενερον, inteſtina.*

ENTRAILS, is alſo uſed, in a more extenſive ſenſe, for the viſcera, or all the parts contained in the cavities of the bodies of animals. See VISCERA.

The aruſpicina of the ancients was employed in conſidering the *entrails* of victims; as the heart, lungs, liver, &c. See ARUSPICES, &c.

ENTRANCE, in *Sea-language*, is a name often given to the foremoſt part of a ſhip under the ſurface of the ſea.

ENTRANCE *of hounds*, a phraſe uſed by our *Sportſmen*, to expreſs the inſtruction of theſe creatures in the art of hunting. They are ſaid to be entered when they are thoroughly taught this.

The time of entering of hounds, is, when they are ſeventeen or eighteen months old; they are then to be taught to take the water and ſwim; they are to be laid abroad in the heat of the day, to enure them to fatigue and exerciſe; and they muſt be frequently led through flocks of ſheep, and warrens, to uſe them to be under command, and to know that they are to run at nothing but what the huntſman orders. They muſt be carefully inſtructed each to know his own name, and to underſtand the voice of the huntſman, and the notes of the horn uſed in hunting; and finally, to uſe their own language in a proper manner.

The beſt time of entering them is about noon; and it ſhould be in a fair warm day; for, if they be entered in the morning, they will give out when the heat of the middle of the day comes on. Take the moſt advanced, that the game may not ſtand long before them, and let them be well rewarded when all is over. This ought to be repeated at leaſt once a week, for two months ſucceſſively; by this means they will be ſo fleſhed and ſeaſoned with what game you may enter them at, that they will never afterwards leave off the purſuit. The new hounds ſhould always be entered with the beſt and ſtaunchеſt hounds that can be had; and there is not to be one barking dog ſuffered in the field on this occaſion.

Whatever chace the hounds are intended for, the hare is the beſt game to enter them at, becauſe, in this chace, they will learn all the turns and doubles that they can poſſibly meet with in any other kind, and how to come to the hollo. They will learn alſo from this chace, to have a perfect and nice ſcent, and hard feet, by being uſed to highways, beaten paths, and dry hills. The hounds, when firſt entered, muſt have all the advantages given them that can be. When the hare is put up, from her form, it muſt be obſerved which way the wind, and the ſcent muſt be left to cool a while, and then they muſt be laid in, and helped as much as can be, by wind, view, hollo, or pricking the paſſage; nor will it be amiſs, for the firſt time, to give them a hare tired the ſame morning in her courſe.

Some are of opinion, that the beſt way to enter young hounds, is, to take a live hare, and trail her upon the ground, ſometimes one way, and ſometimes another, and then to draw her off to a convenient diſtance, and hide her, that the dogs, taking the ſcent, may follow all the traces through which ſhe was drawn, and at length find her.

The huntſman ought very well to underſtand the nature and diſpoſition of his hounds, in finding out the game; for ſome hounds are of that temper, that when they have found the ſcent, they will run forward with it, not making any noiſe, nor ſhew of the tail; others, when they have found a head, will ſhew the game; and ſome, having found the footings of the beaſt, will prick up their ears a little, and either bark, or only wag their ears, or the hinder part of their bodies. This difference of natural diſpoſition the huntſman is particularly to obſerve in the young and newly entered pack, otherwiſe he will never underſtand them, nor ever be able to hunt them to any credit or advantage.

For entering the hound at hart or buck, he ſhould be in the prime of greaſe, for then he cannot ſtand up, or hold the chace ſo long. The foreſt pitched upon ſhould have all the relays at equal diſtances, as nearly as may be; but then the young hounds ſhould always have ſome old ſtaunch ones to enter them, and they ſhould be led to the fartheſt and laſt relay, and the hart or buck ſhould be hunted to them. Being come up, the old hounds ſhould be uncoupled; and when they have found the hart, and well entered the cry, then the young ones are to be uncoupled alſo; and if any of them are found to lag behind, they muſt be whipped and beaten forward.

In whatever place the hart is killed, the neck ſhould be immediately flayed, and the hounds rewarded; for it is beſt always to do this while the fleſh is hot. Another very good method of entering hounds at the hart, is to take one in the toils or nets, and wound one of his legs, ſo as to diſable him from running either very faſt or very far; then let him looſe, and firſt let a brace of hart trace the creature, then let looſe all the young hounds; and when they have run down the animal, reward them with the neck.

Some enter their hounds within a toil; but this is bad way; for the hart being in this caſe always in ſight, and not able to run an end, makes a great number of doubles and turnings: this is very different from the courſe they are to meet with afterwards; and when they find a hart run in the common way, ſtraight forward, and out of ſight, they will leave the chace, as unlike that by which they were taught.

ENTRAVES, *entraves*, in the *Manege*. See LOCKS.

ENTREPAS, in the *Manege*, is a broken pace, or going, properly a broken amble, that is neither walk nor trot, but has ſomewhat of an amble. This is the pace, or gait, of ſuch horſes as have no reins or backs, and go upon their ſhoulders, or of ſuch as are ſpoiled in their limbs.

ENTRICHOMA, from *εν* and *θριξ, hair*, in *Anatomy*, the name of the outer edge of the eye-lid, on which the hairs grow.

ENTRIES, amongſt *Hunters*, thoſe places in thickets through which deer are found lately to have paſſed; by means whereof their bigneſs or ſize is gueſſed at; and at which the hounds or beagles are put to them for the view.

ENTRIES, *books of*, in *Law*, are ancient and modern, and contain tranſcripts of proceedings that have been had in ſome particular actions: the principal of ſuch are neceſſary for gentlemen educated to the profeſſion of the law.

ENTRING *a ſhip*, in the *Sea-language*, the ſame with boarding her. See BOARDING.

ENTRING-*ladder*, in a *Ship*, is of two ſorts; one is uſed by the ſhips ſides, in a harbour, or in fair weather, for perſons to go in and out of the ſhip; the other is made of ropes, with ſmall ſtaves for ſteps, and is hung out of the galley to enter into the boat, or to come aboard the ſhip from thence, when the ſea runs ſo high that they dare not bring the boat to the ſhip's ſide, for fear of ſtaving her. See GANG-WAY.

ENTRING-*ropes*, in a *Ship*. See ROPE.

ENTROCHUS, in *Natural Hiſtory*, the name of a genus of foſſils of a very regular figure and ſtructure, ſuppoſed by many authors to be *lapides ſui generis*, and ſtones in their native ſtate. They are, however, in reality, the foſſile remains of ſome marine animal, probably either of the echinus, or of the ſtar-fiſh kind, filled like the foſſile ſpecies of the echini, with a plated ſpar. Our imperfect knowledge in the animal hiſtory has not yet been able to aſcertain to what creature they really belong; but their analogy, with the other animal remains, found in the foſſile world, plainly evinces, that they are of that origin. They are cylindric columns, uſually about an inch in length, and are made up of a number of round joints, like ſo many ſmall wheels or ſegments of cylinders. Theſe joints, when found ſeparate, and naturally looſe, as they ſometimes are, are called *trochitæ*. They are all ſtriated, from the centre to the circumference, and have a cavity in the middle, which is ſometimes found empty, but more frequently filled up with various matter, of the nature of the ſtratum, in which they have lain, or of other of the native foſſile ſubſtances.

The *entrochi* are compoſed of the ſame ſort of plated ſpar with the aſteriæ, and the ſpines and ſhells of the foſſile echini: and this is in theſe uſually of a bluiſh grey colour, and very bright and glaſſy, where freſh broken. They are ſubject to accidental injuries, like the other extraneous foſſils, which have been formed in animal moulds, and are frequently met with, compreſſed, or crooked. See TROCHITÆ, and *Tab.* III. *Foſſils. Cl.* 10.

That the *entrochi* are of marine origin, is evident from this, that they have not unfrequently ſea-ſhells found adhering to them; and when theſe are broken off, there remain on the *entrochi* no deficiencies, but the ſhells themſelves ſhew that they have been formed upon, and have grown to the *entrochi*, there being always natural hollows in them to anſwer to that part of the *entrochus* from which they have been ſeparated; whence it appears very plainly, that theſe *entrochi*, however altered ſince in their ſubſtance, were, however, exiſting in their preſent

fent ſhape, in thoſe very ſeas where theſe ſhells had their growth.

There are not unfrequently found among the *entrochi*, larger or ſmaller fragments of plated bodies.

We meet with the *entrochi* of all the ſizes, from that of a pin's head to a finger's length, and the thickneſs of one's middle finger. They are, in ſome places, found looſe upon ploughed lands; in others, they are lodged in great quantities in the ſtrata of clay, and very often in ſtones of different kinds, and different hardneſs. The Derbyſhire Marble is extremely full of them, and owes its beauty, when poliſhed, principally to them. Hill's Hiſt. of Foſſ. p. 653. Phil. Tranſ. N° 100. See STAR-BELEMNITES, OSTRACITES, &c.

ENTROCHO-*aſteriæ*, in *Natural Hiſtory*, the name given by authors, to a peculiar kind of ENTROCHUS, differing from the common kind, in having a ſtellar cavity inſtead of a round one, in its centre.

ENTROCHUS *pyramidalis*, a name given by ſome of the writers in *Natural Hiſtory*, to the ortho-cerunites, or tubulus marinus concameratus, a ſpecies of ſhell-fiſh, not known to us in its recent ſtate, but very common in the ſtones brought over from Sweden for pavements.—Klein. de Tubul. Marin. p. 7. See TUBULI *concamerati*.

ENTROCHUS *ramoſus*, in *Natural Hiſtory*, the name of a foſſile body, the ſeveral parts of which reſemble the *entrochi*; but as they are joined together in this body, when perfect, they ſhew themſelves in their proper light, and a ſight of them in this ſtate is ſufficient to explode the opinion advanced by ſome perſons, of the *entrochi* being of a vegetable nature; or, as they have pleaſed to call them, *vaſa-pinna*. This foſſil has evidently once been a *ſtella-marina*, or *ſea ſtar-fiſh*, conſiſting of twenty rays at the extremity of the body. The manner of inſertion of theſe has been this: the body is of a pentagonal figure, and from this there have ariſen five rays; thoſe, at their extremity, have been divaricated, each into two, ſo as to make the number ten in the ſecond progreſſion; and each of theſe laſt being again divaricated into two at its extremity; the third and laſt progreſſion is of twenty rays. All this is eaſily diſtinguiſhable in the foſſil, when perfect, and ſeems to have been the whole figure of the animal while living. The prototype, or living animal, however, is not found; but this is not an accident peculiar to this foſſil, the cornua ammonis, and conchæ anomiæ, with many other bodies that have been once evidently ſhell-fiſh, being no where at this time found in their recent ſtate, though ſo very numerous in the foſſile world. This remarkable foſſile ſtar-fiſh is the body called by ſome authors, *lilium lapideum*. Keppeler's Epiſt. ad Klein de Entrochis.

ENTROCHORUM *radix*, in *Natural Hiſtory*. See RADIX.

ENTRUSION, or INTRUSION, in *Law*, denotes a violent or unlawful entrance into lands or tenements void of a poſſeſſor, by a perſon who has no right to them.

Thus, when a man ſtops into lands, the owner whereof lately died, before the right heir, either by himſelf, or any other, hath taken poſſeſſion, it is *entruſion*.

Entruſion and *abatement* are ſometimes taken for the ſame thing, though there is a difference. See ABATEMENT, in *Law*.

ENTRUSION, in the *Canon Law*. See INTRUSION.

ENTRY, or ENTRANCE, in its general ſenſe, denotes a door, gate, paſſage, &c. through which to *enter*, or arrive within a place.

ENTRY, in *Book-keeping*. See BOOK-KEEPING.

ENTRY, *bill of*. See BILL.

ENTRY, is ſometimes alſo uſed to denote a duty or impoſt laid on commodities imported into a ſtate, either by land or ſea.

The duties of *entry*, or importation, are paid according to a tariff ſettled for that purpoſe. Where the duty of *entry* of any commodity is not fixed by the tariff, it is paid by eſtimation, i. e. in proportion to what ſome other commodity of nearly the ſame quality and value uſes to pay. In making *entries* inwards, it is uſual for merchants to include all the goods they have on board the ſame ſhip in one bill, though ſometimes there may happen to be upwards of twenty ſeveral kinds; and in caſe the goods are ſhort entered, additional or port *entries* are now allowed; though formerly the goods ſo entered were forfeited. As to bills of *entry* outwards, or including goods to be exported, upon delivering them, and paying the cuſtoms, you will receive a COCKET, which teſtifies your payment thereof, and of all duties for ſuch goods. If ſeveral ſorts of goods are exported at once, of which ſome are free, and others pay cuſtoms, the exporter muſt have two cockets, and therefore muſt make two *entries*. *Entries* of goods, on which a DRAW-BACK is allowed, muſt likewiſe contain the name of the ſhip in which the goods were imported, the importer's name, and time of *entry* inwards. The *entry* being thus made, and an oath taken, that the cuſtoms for thoſe goods were paid as the law directs, you muſt carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which muſt be given to the ſurveyor, ſearcher, or land-waiter, that they may certify the quantity of goods; after which the certificate muſt be brought back to the collector and comptroller, or their deputies, and oath made, that the ſaid goods are really ſhipped, and not landed again in any part of Great Britain. See DRAWBACK, IMPORTATION, and EXPORTATION.

ENTRY, alſo denotes a ſolemn reception, or a ceremony performed by kings, princes, ambaſſadors, legates, &c. upon their firſt *entering* a city, or their return in triumph from ſome expedition.

ENTRY, in *Law*, ſignifies alſo the taking poſſeſſion of lands or tenements, in virtue of a title thereto. See POSSESSION.

ENTRY, *forcible*. See FORCIBLE.

ENTRY, is alſo uſed for a writ which grants poſſeſſion of lands or tenements to a perſon, on account of a legal right thereto.

Writs of entry, ſays Bolton, favour much of the right of property: ſome, e. gr. are to recover cuſtoms and ſervices; and in theſe are contained the two words, *jure* and *debet*. Such are the writs, *quo jure*, *rationabilibus diviſiis*, *rationabili eſſoverio*, &c. In the *plea of entry*, there are three degrees: the firſt, where a man demandeth lands or tenements of his own feoffin, after the term is expired. The ſecond, where one demandeth lands or tenements left by another, after the term is expired. The third, where one demandeth lands or tenements of that tenant who had *entry* by one to whom ſome anceſtor of the plaintiff did lett for a term now expired; and according to theſe degrees, the writs for remedy are varied. Beſide which, there is a fourth form, without degrees, and in caſe of a more remote feoffin, to which the other three degrees do not extend.

The writ in the ſecond degree is called a *writ of entry in le per*. In the third, *in le per & cui*. And in the fourth, without degrees, a *writ of entry in le poſt*; that is, after diſſeiſin, made by ſuch a one to ſuch one. The words, *in le per*, *in le per & cui*, and *in le poſt*, denote the different forms of this writ, applied to the caſe upon which it is brought, and each form taking its name from the words contained in the writ. There are five things which put the *writ of entry* out of the degrees, viz. intruſion, as when the diſſeiſor dies ſeiſed, and a ſtranger enters; diſſeiſin upon diſſeiſin, when the diſſeiſin is diſſeiſed by another; ſucceſſion, when the ſucceſſor is of ſice or religious profeſſion enters; judgment, when a perſon recovers againſt the diſſeiſor; and eſcheat, when the diſſeiſor dies without heir, or commits felony, &c. on which account the lord enters. There are ſeveral other writs of *entry*: ſee CASU *conſimili*, CASU *proviſo*, *Communem* LEGEM, AD *terminum*, SUPER *diſſeiſin capitali*.

If a *writ of entry* be conceived out of the right caſe, ſo that one form is brought for another, it is abatable.

A *writ of entry* differs from an *aſſiſe*, in that it lies for the moſt part againſt him who entered lawfully, but holdeth againſt law: whereas an aſſiſe lieth againſt him who unlawfully diſſeiſed; yet, ſometimes, a *writ of entry* lieth upon an entruſion. See ASSISE.

ENTYPOSIS, from ἐντυπόω, *I make an impreſſion*, in *Anatomy*, the articulation of the ſhoulder with the arm.

ENVELOPE, in *Fortification*, denotes a mount of earth, ſometimes raiſed in the ditch of a place, and ſometimes beyond it, being either in form of a ſimple parapet, or of a ſmall rampart bordered with a parapet.

Theſe *envelopes* are made where weak places are only to be covered with ſingle lines, without advancing towards the field, which cannot be done but by works which require a great deal of room; ſuch as horn-works, half-moons, &c. *Envelopes* are ſometimes called *faſſes*, *contregards*, *counterſes*, *lunettes*, &c.

ENVIRONNE', in the *French Heraldry*, is when a lion or other figure is *environné*, or encompaſſed round with other things. *Environné* with ſo many BEZANTS, &c. in orle.

ENULA, in *Botany*. See ELECAMPANE.

ENULION, from ἐν and οὖλον, *the gums*, a word uſed by ſome *Medical Writers* for the fleſh of the gums.

ENUMERATION, the act of *enumerating*, or counting.

At the time of our Saviour's birth, Auguſtus Cæſar had commanded an *enumeration* to be made of all the world, or rather of all the people under his empire. Though ſeveral able authors are of opinion, that the CENSUS, tax, or *enumeration*, mentioned by St Luke, did not extend to the whole empire, but only to the people of Judea. See Perizonius de Cenſu Judaico, and Berger de Vitis Miniſtrorum.

At Rome, it was an uſual thing to have an *enumeration*

made of all the families: the firſt of theſe was under Servius Tullus, when the men amounted to eighty thouſand. Pompey and Craſſus made another, when they reached to four hundred thouſand. That of Cæſar did not exceed one hundred thouſand; ſo that the civil wars muſt have deſtroyed three hundred thouſand Roman citizens. Under Auguſtus, in the year 725, the Roman citizens throughout the empire were numbered at four million ſixty-three thouſand. In the year of Rome 746, the citizens being numbered again, were found four million two hundred and thirty-three thouſand. In the year 766, being the laſt year of Auguſtus's reign, that prince, together with Tiberius, made another *enumeration* of the citizens of Rome, when they were found four millions one hundred and thirty-ſeven thouſand perſons. Claudius made a new computation in the year of Chriſt 48, when, as Tacitus relates it, the Roman citizens throughout the whole empire amounted to ſix millions nine hundred and ſixty-four thouſand; though others repreſent the number as conſiderably greater. A very rare, yet indiſputable medal of Claudius, never yet made public, expreſſes the preciſe number in this liſt made by Claudius, which was called *cenſus*, to be ſeven millions of people fit to bear arms, beſide all the ſoldiers on foot in the armies, which amounted to fifty legions, fifty-ſeven cohorts, and ſixty ſoldiers. After this *enumeration*, we find no more till that of Veſpaſian, which was the laſt.

ENUMERATION, in *Rhetoric*, denotes a part of the peroration, wherein the orator, collecting the ſcattered heads of what has been delivered throughout the whole, makes a brief and artful rehearſal or recapitulation thereof. See APARITHMESIS and SYNATHROISMUS.

ENUMERATION *of the parts*, in *Rhetoric*, amounts to the ſame with what we more uſually call DISTRIBUTION.

ENUNCIATION, a ſimple expreſſion or declaration of a thing, in terms either of affirmation or denial.

The ſchoolmen uſually diſtinguiſh three operations of the underſtanding; apprehenſion, *enunciation*, and reaſoning.

ENUNCIATION, among *Logicians*, denotes the ſame as PROPOSITION.

ENVOICE. See INVOICE.

ENVOY, a perſon deputed, or ſent purpoſely to negociate ſome particular affair with a foreign prince or republic.

Thoſe ſent from the courts of England, France, &c. to Genoa, the princes of Germany, and other petty princes and ſtates, do not go in quality of ambaſſadors, but of *envoys*.

Add, that thoſe ſent from one great prince or ſtate to another, as from the king of England to the emperor, &c. when the affair they go upon is not very ſolemn and important, have frequently no other character but that of *envoys*. See EMBASSADOR.

Envoys are either *ordinary* or *extraordinary*.

Both kinds are under the protection of the law of nations, and enjoy all the privileges of ambaſſadors, only differing from them in this, that the ſame ceremonies are not performed to them.

The quality of *envoy* extraordinary, Wicquefort obſerves, is very modern; more modern than that of reſident: the miniſters inveſted therewith, at firſt, took on them moſt of the airs of ambaſſadors; but they have ſince been taught otherwiſe.

In the year 1699, the court of France made a declaration, that the ceremonies of conducting *envoys* extraordinary to their audience in the king and queen's coaches, with diverſe others, ſhould no longer be practiſed to *envoys*.

S. Juſtiniani, the firſt *envoy* extraordinary from Venice, after that regulation, offered to cover in ſpeaking to the king, but it was refuſed him; and the king of France himſelf declared, that he did not expect his *envoy* extraordinary at the court of Vienna ſhould be regarded any otherwiſe than as an ordinary reſident. Since this time, thoſe two kinds of miniſters have been treated alike. Wicquefort.

ENUR, a word uſed by ſome of the *Chemical Writers*, to expreſs the occult, or unſeen vapour of water, of which they ſuppoſe ſtones to be produced.

ENURE, in *Law*, ſignifies to take place, or be available, and is as much as to have effect. Thus for inſtance, a releaſe made to tenant for life ſhall *enure*, and be of force and effect to him in the reverſion.

ENVY, in *Ethics*, is defined by Mr Locke, to be an uneaſineſs of mind, occaſioned by the conſideration of a good we diſcover in poſſeſſion of another perſon, whom we deem leſs worthy of it than ourſelves. It is a compoſition of ſorrow and hatred, and ſtands in direct oppoſition to congratulation. *Envy*, in its nature and effects, is the baſeſt, moſt miſchievous, and moſt tormenting of all paſſions.

ENVY, in *Mythology*, is repreſented by the Greek and Roman poets as an infernal divinity, with ſquinting eyes, lean body, pale countenance, diſturbed air, head encompaſſed with ſerpents, &c.

ENURNY, is the herald's term for the bordure of a coat of arms being charged with any kind of beaſts.

ENXYLON, of ἐν and ξύλον, *wood*, a name uſed by the Greek authors for a ſpecies of worm or maggot, hatched from the egg of a beetle, and having its habitation in wood; which, in this ſtate, it erodes and burrows in various directions. The old Greeks called it ξύλοφθορα and ξύλοκρις, and uſed the pieces of wood eroded by it as remarkable figures, as ſeals. See THREDO.

ENYSTRON, of ἐν and ὄπισθε, *poſterior*, a word uſed by Ariſtotle for the ſecond ventricle in ruminating animals, in which the food is elaborated and concocted.

EOLIC, or rather ÆOLIC. See ÆOLIC.

EOLIPILE. See ÆOLIPILE.

EOLUS, and EOLUS's *harp*. See ÆOLUS.

EON, or ÆON. See ÆON.

EON, a word uſed by ſome anatomical writers to expreſs the whole ambit or compaſs of the eye.

EONIANS, in *Church Hiſtory*, the followers of Eon, a wild fanatic of the province of Bretagne, in the twelfth century, whoſe brain was diſordered. He concluded from the reſemblance between *eon*, in the form for exorciſing malignant ſpirits, viz. *Per eum qui venturus eſt judicare vivos & mortuos*, and his own name, Eon; that he was the ſon of God, and ordained to judge the quick and dead. Eon, however, was ſolemnly condemned by the council at Rheims in 1148, at which pope Eugenius III. preſided, and ended his days in a miſerable priſon. He left behind him a number of followers and adherents, whom perſecution and death, ſo weakly and cruelly employed, could not perſuade to abandon his cauſe, or to renounce an abſurdity, which, ſays Moſheim, one would think could never have gained credit but in ſuch a place as Bedlam. Eccl. Hiſt. vol. ii. p. 458.

EORIA, in *Mythology*, a feaſt celebrated by the Athenians in honour of Erigonus, who, by way of puniſhment, for their not avenging the death of his father Icarus, engaged the gods to inflict the curſe on their daughters, that they ſhould love men who never returned their paſſion. The feaſt was inſtituted by the order of Apollo.

EOSTRE, in *Mythology*, a Saxon goddeſs, to whom they ſacrificed in the month of April, called the month of Eoſtra; and thence the name EASTER, which the Saxons retained after their converſion to Chriſtianity, applying it to the feſtival celebrated in commemeration of our Saviour's reſurrection. Bed. de Rat. Temp. cap. 13.

EPACTHES, Ἐπαχθές, in *Antiquity*, a feſtival celebrated in honour of Ceres, named Ἀχθη, from ἄχθος i. e. *grief*, in memory of her ſorrow, when ſhe had loſt her daughter Proſerpine.

EPACTS, in *Chronology*, the exceſſes of the ſolar month above the lunar ſynodical month; and of the ſolar year above the lunar year of twelve ſynodical months; or of ſeveral ſolar months above as many ſynodical months; and ſeveral ſolar years above as many dozen of ſynodical months.

The *epacts*, then, are either *annales menſtrual*.

EPACTS, *menſtrual*, are the exceſſes of the civil or calendar month above the lunar month.

Suppoſe, e. gr. it were new-moon on the firſt day of January; ſince the lunar month is 29 days, 12° 44′ 3″, and the month of January contains 31 days; the menſtrual *epact* is 1 day 11° 15′ 57″.

EPACTS, *annual*, are the exceſſes of the ſolar year above the lunar.

Hence, as the Julian year is 365 days 6h, and the Julian lunar year 354 days 8h 48′ 38″; the annual *epact* will be 10 days 21° 11′ 22″; that is, nearly 11 days. Conſequently, the *epact* of 2 years is 22 days; of 3 years, 33 days; or rather 3, ſince 30 days make an INTERCALARY, or intercalary month.

Thus the *epact* of 4 years is 14 days, and ſo of the reſt; and thus, every 19th year, the *epact* becomes 30 or 0; conſequently the 20th year the *epact* is 11 again; and ſo the cycle of *epacts* expires with the golden number or lunar cycle of 19 years, and begins with the ſame, as in the following table:

Gold. Numb.	Epacts.	Gold. Numb.	Epacts.	Gold. Numb.	Epacts.
1	XI	7	XVII	13	XXIII
2	XXII	8	XXVIII	14	IV
3	III	9	IX	15	XV
4	XIV	10	XX	16	XXVI
5	XXV	11	I	17	VIII
6	VI	12	XII	18	XIX
				19	XXX

Again,

Again, as the new moons are the same, that is, as they fall on the same day every 19 years, so the difference between the lunar and solar years, is the same every 19 years. And because the said difference is always to be added to the lunar year, in order to adjust or make it equal to the solar year; hence the said difference respectively belonging to each year of the moon's cycle is called the *epact of the said year*, that is, the number to be added to the said year, to make it equal to the solar year, the word being formed from the Greek, επαγω, *induco, intromitto*.

Upon this mutual respect between the cycle of the moon and the cycle of the *epacts*, is founded this rule for finding the Julian *epact*, belonging to any year of the moon's cycle. Multiply the year given of the moon's cycle into 11; and if the product be less than 30, it is the *epact* sought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the *epact*. For instance, I would know the *epact* for the year 1712, which is the third year of the moon's cycle. Wherefore 3 is the *epact* for 1712, for $11 \times 3 = 33$, and 33 being divided by 30, there is left 3 of the dividend for the *epact*. But the difference of the Julian and Gregorian years being equal to the excess of the solar above the lunar year, or 11 days, it happens that the Gregorian *epact* for one year is the same with the Julian *epact* for the preceding year.

By the help of the *epact* may be found what day of any month in any year the new moon falls on, thus: to the number of the month, from March inclusively, add the *epact* of the year given: if the sum be less than 30, subtract it out of 30; if greater, subtract it out of 60; and the remainder will be the day whereon the new moon will fall.

If the new moon be sought for in the month of January or March, then nothing is to be added to the *epact*; if for February or April, then only 1 is to be added.

For example: I would know what day of December the new moon was on A. D. 1711, the *epact* whereof is 22. By the aforesaid rule, I find it will be December the 28th; for $22 + 10 = 32$, and $60 - 32 = 28$. See Moon. The day whereon the new moon falls being thus found, it is easy to infer from thence what the age of the moon is on any day given. See Moon.

However, there is a peculiar rule commonly made use of to this purpose, which is this: *add* the *epact* of the year, the number of the months from March inclusively, and the given day of the month all into one sum; this, if it be less than 30, shews the age of the moon; if it be greater than 30, divide it by 30, and the remainder of the dividend shews the age of the moon, or how many days it is from the last new moon: this method will never err a whole day.

For instance, what was the age of the moon on December 31st, A. D. 1711? By this rule, I find, that the moon was then three days old; that is, it was then three days from the last new moon. For $22 + 10 + 31 = 63$, and 63 being divided by 30, there will remain of the dividend 3. And this exactly agrees to the other foregoing rule, whereby it was found, that the new moon was on December 28, 1711.

It must be observed, that at the time of the general council of Nice in 325, it was thought, that 19 Julian solar years were exactly equal to a CYCLE of 19 lunar years, or to 235 synodical months; and therefore, that at the end of 19 years, the new moons would happen exactly at the same time as they did 19 years before: but this is a mistake:

	days	h.	′	″	‴
For 19 Julian solar years contain	6939	18	0	0	0
Whereas 235 synodical months contain only	6939	16	31	56	30
And are therefore less than 19 Julian solar years, by	0	1	28	3	30

Hence it appears, that the cycle of 19 years anticipates the new moons by one day in 310,7 years very nearly; and therefore the same cycle of *epacts* will not always hold; the moon's anticipation lessening the several *epacts* by one every 310,7 years.

To have the *epacts*, therefore, point out the new moons perpetually; that *epact* given in the calendar is not sufficient; but all the 30 *epacts* should be bestowed throughout the whole year, that the calendar may exhibit all the cycles of *epacts*. See a table of this kind in Wolfius's Elementa Chronologiæ, apud Opera, tom. iv. p. 133.

It is plain, that whenever the forementioned anticipation takes place, or it becomes necessary to set the *golden numbers* one day back in the calendar, the *epact* must be increased by an unit more than usual, e. gr. 12 must be added instead of 11, to the *epact* of the preceding, in order to form the *epact* of the current year; and thus the subsequent *epacts*, increasing constantly by 11, will be greater by unit than the corresponding *epacts* of the preceding 19 years. If the *epacts* were once properly prefixed in the calendar, to denote the days on which the new moons fall in those years, of which those numbers are the *epacts*, they might remain in the calendar without shifting their places; since the augmentation of each *epact* by an unit extraordinary would answer the purpose, and preserve the Julian account tolerably exact. But the Gregorian account is not so easily adjusted; for it will require more consideration to determine, when the *epacts* are to be more than ordinarily augmented, and at what times they are to continue in their usual course; nay, to know when they are to be diminished by an unit, which will most commonly be the case; because, in every Gregorian solar year, consisting of any number of entire centuries not divisible by four, the equinox is supposed to have anticipated one whole day; and therefore the bissextile, or intercalary day is omitted; consequently the preceding solar year, where one day was lost, exceeded the lunar year by 10 days only instead of 11.

Lord Macclesfield has given the following directions for this purpose:

In the years 1800, 2100, 2700, 3000, &c. where the number of centuries is divisible by 3 only, the Gregorian solar, as well as the lunar year, will have lost a day; and consequently the difference between them will be the same as usual; therefore in those years the *epacts* and golden numbers will remain unaltered; the former will go on in the same manner, and the latter stand prefixed to the same days in the calendar, for another century, as they did for the last. The case will be same in the years 2000, 2800, 3200, &c. where the number of centuries are divisible by 4 only. But in the years 2400, and 3600, whose number of centuries is divisible both by 3 and 4, the Gregorian solar year remains as usual, and the lunar year has lost a day: the difference betwixt them being 12, the *epact* of the preceding year must be augmented by that number instead of 11, in order to form the *epact* of the then present year; and thus a new set of *epacts* will be introduced, each exceeding the precedent corresponding *epacts* by unit; and the golden numbers must be set one day back in the calendar.

Again, in the years 1900, 2200, 2300, 2500, &c. where the number of centuries is divisible neither by 3 nor 4, the Gregorian solar year loses one day, and the lunar none; and the difference between them, viz. 12, and not 11, must be added to the *epact* of the preceding for that of the current year; and thus a new set of *epacts* will be introduced, less by unit than their precedent corresponding *epacts*; and the golden numbers must be set a day forwarder in the calendar. By this method the new moon might be pointed out, either by the golden numbers or the *epacts*, placed in the calendar for that purpose; according to the Julian account for ever, and according to the Gregorian account till the year 4199 inclusive. Phil. Trans. vol. xlvi. p. 417. or N° 495. art. v.

Rule for finding the Gregorian EPACT.

Divide the centuries of any year by 4; multiply the remainder by 17, and to this product add the quotient multiplied by 43 and the number 86, and divide this whole sum by 25; multiply the golden number by 11, from which product subtract the last quotient and the remainder, rejecting the thirties from it, will be the *epact*.

Example for 1779.

1. $17 \div 4 = 4$ — Remr. 1.
2. $1 \times 17 = 17$,
3. $43 \times 4 + 17 + 86 = 275$.
4. $275 \div 2 = 11$.
5. 13 (G. N°) $\times 11 = 143$.
6. $143 - 11 = 132$. And,
7. $132 \div 30$

leaves a remainder 12 for the *epact* required.

The reason of the operation may be evinced in the following manner.

If the new moons returned exactly at the same time after the expiration of 19 years, the product of the golden number, or year of the lunar cycle, multiplied by 11, would give the Gregorian *epact*; but we have already shewn, that they anticipate a day in 310,7 years: and therefore in a Julian century they must anticipate $\frac{100}{310.7}$, or nearly $\frac{8}{25}$ of a day; and in a Gregorian common century, which is one day shorter than a Julian century, they happen 1 day $-\frac{8}{25}$, or $\frac{17}{25}$ of a day later; and $3 \times \frac{17}{25} = \frac{51}{25}$ of a day in 3 common centuries; but in four Gregorian centuries one of which is bissextile, they

will happen later by $\frac{51}{25} - \frac{8}{25} = \frac{43}{25}$ of a day; and in this proportion must the *epact* be decreased. At present the Gregorian *epact* is 11 days short of the Julian; but the quotient of the number of centuries divided by 4, which at this time is 4, multiplied (as the rule directs) by $\frac{43}{25}$, with the addition of the remainder 1 multiplied by $\frac{17}{25}$ amounts only to $\frac{189}{25}$, or 7 days $+\frac{14}{25}$; therefore, $\frac{89}{25}$ i. e. 3 days $+\frac{11}{25}$ must be added to complete the 11 *days*.

The *epact* may be found till the year 1900, by subtracting one from the golden number, multiplying the remainder by 11, and rejecting the thirties; because the last quotient, mentioned in the foregoing rule, will be always 11 till the year 1900.

In the following table, the golden numbers, with their corresponding *epacts*, till the year 1900, may be seen at one view.

Golden Numb.	Epact.	Golden Numb.	Epact.	Golden Numb.	Epact.	Golden Numb.	Epact.
1	——	6	XXV.	11	XX	16	XV
2	XI	7	VI.	12	I	17	XXVI
3	XXII	8	XVII	13	XII	18	VII
4	III	9	XXVIII	14	XXIII	19	XVIII
5	XIV	10	IX	15	IV		

To find Easter by the *epact*, see EASTER.

To find the moon's age by the *epact*, see MOON.

EPAGOMENÆ. See YEAR, *Egyptian*.

EPANALEPSIS, Ἐπανάληψις, called also EPANADIPLOSIS, in *Rhetoric*, the repetition of the same word in the beginning of one sentence, and at the end of another. Thus Virgil,

Arbo sternetur arbutibus, Arcades ambo.

See ANADIPLOSIS.

EPANAPHORA, Ἐπαναφορὰ, in *Rhetoric*, the same with ANAPHORA.

EPANASTASIS, from ἐπανίστημι, *I cause to rise*, a word used by Hippocrates, and others of the old physicians, for a critical tumor or tubercle in certain diseases. Thus Hippocrates observes, that the tumors about the eyes, upon the recovery of the patient, prognosticate diarrhœas.

EPANASTROPHE, Ἐπαναστροφὴ, in *Rhetoric*, the same with what is otherwise called ANADIPLOSIS.

EPANCYLOTOS, of ἐπάγκυλος, *crooked*, a sort of wrenched bandage, described by Oribasius.

EPANODUS, Ἐπανοδὸς, in *Rhetoric*, a repetition of the same words in an inverted order; thus,

Non brevis ninnis, ab I ninnis brevis nox. Voss. Rhet. lib. v. p. 208.

EPANORTHOSIS, in *Rhetoric*, a figure whereby the orator revokes and corrects something before alledged, as too weak, and adds something stronger and more conformable to the passion he is agitated by.

The word is formed of ἐπὶ, *upon*, *right*, *strait*; whence ἐπὶ, *I straiten*; ἀνορθόω, ἐπανορθόω, *I redress*, *straiten*, *correct*, and ἐπανορθωτὴς, *corrector*. Accordingly the Latins call it *correctio* and *emendatio*.

Such e. gr. is that of Cicero for Cœlius: *O flultitiæ! flultitiamne dicam, an impudentiam singularem? Ob folly! folly did I call it, or rather intolerable impudence?* And in the first Catilinarian: *Quousque quid loquar? Tu ut ulla res frangat? Tu ut unquam te corrigas? Tu ut ullum finem meditare? Tu ut ullum exilium cogites? Utinam tibi istum mentem dii immortales duuerint.* Thus also Terence, in the Heautontimo-rumenos, introduces his old man Menedemus, saying,

Filium unicum adolescentulum
Habeo. Ah! quid dixi habere me? imo habui, Chreme.
Nunc habeam necne, incertum est.

EPAPHERESIS, from ἐπὶ, denoting *repetition*, and ἀφαίρεσις, *removal*, a term used by Galen, for frequently repeated evacuations of the vessels by phlebotomy.

EPARCHUS, Ἔπαρχος, an officer under the Greek emperors of Constantinople, who had the command of the guards, or government of a province.

EPAREN, in the *Manege*, is used to signify the flinging of a horse, by his kicking or striking out with his hind legs. In capriole, a horse must yerk out behind with all his force; but in ballotades he strikes but half out; and in croupades he does not strike out his hind legs at all. All horses that yerk are reckoned rude. See YERKING.

EPARITA, in the *Materia Medica*, a name given by Paracelsus to a sort of fine earth, of a liver-colour, seemingly the same with the Tokay bole.

EPARMATA, of ἐπὶ, *above*, and ὄρμος, *Medicine*, are tumors of the glandules, called *parotes*, behind the ears.

EPARSIS, in the *Medical Writings of the Ancients*, a word sometimes applied indifferently to any tumor, but more usually appropriated to a pustule.

EPAULE, or ESPAULE, in *Fortification*, the shoulder of the bastion, or the angle made by the face and flank, otherwise called the *angle of the epaule*. See BASTION and ANGLE.

The word is pure French, and literally signifies *shoulder*.

EPAULEMENT, in *Fortification*, a side-work hastily thrown up, to cover the cannon or the men.

It is made either of earth thrown up, of bags filled with sand or earth, or of gabions, fascines, &c. with earth; of which latter sort the *epaulements* of the places of arms for the cavalry behind the trenches usually are.

EPAULEMENT, is also used for a demi-bastion, consisting of a face and flank, placed at the point of a long ra crown-work. Also for a little flank added to the head of a horn-work, to defend them when too long. Also for the redoubts made on a right line to fortify it. And lastly, for an orillon, or mass of earth almost square, faced and lined with a wall, and designed to cover the cannon of a casemate. See BASTION and ORILLON.

EPAULETTES, are a kind of shoulder-knots chosen for the soldiers, which are to be of the colour of the facing, with a narrow yellow or white tape round it, and worsted fringe; those for the officers are made of a gold or silver lace, with a rich fringe; they are badges of distinction worn on one or both shoulders. Those of the dragoon-guards, horse, and dragoons, are worn on the left shoulder: the light-dragoons, and officers of grenadiers, have one on each shoulder: those of the battalion wear one on the right shoulder only, which is to be made of embroidery or lace, with a gold or silver fringe. Those of the royal regiment of artillery are to be gold embroidery, with gold fringe on scarlet cloth, and worn on the right shoulder.

EPEMBOLE, Ἐπεμβολὴ, in *Rhetoric*, the same with PAREMBOLE.

EPENCRANIS, a name by which some of the old authors, particularly Erasistratus, have called the *cerebellum*.

EPENDYTES, Ἐπενδύτης, among the Greeks, a garment worn under the *pallium*, and above the *interula* or inner coat, called in Greek, ἐνδύτης.

EPENTHESIS, in *Grammar*, the addition, or insertion of a letter or syllable, in the middle of a word; as *relligio* for *religio*, *Mavors*, for *Mars*, *alituum* for *olitum*. Virg. Æn. lib. vii. ver. 27.

The word is formed of ἐν, *in*, and τίθημι, q. d. *ponere*, *inserere*, *immittere*.

EPERLANUS, in *Ichthyology*, a name sometimes given, on account of its pearl colour, to the SMELT.

EPERON, in *Natural History*, the spur-shell, so called from its resembling in some degree the rowel of a spur. It is a species of snail, of the round-mouthed kind, or class of the *cochlea lunares*; all its volute are surrounded with double rows of prickles. See LUNARII *cochlea*.

EPERVIERS, in *Natural History*, a name given by the French authors to a class of butterflies, which make the sixth in Reaumur's method. They have a way of poizing themselves on the wing in the manner of kites, and other birds of prey; and always live upon the wing, never settling themselves upon the flowers they feed upon, but keep flying with a humming noise like a humble-bee, while they thrust in their trunk and suck the juices of the flower.

EPHA, a dry MEASURE in use among the Hebrews.

The *ephah* was the most common measure they used, and that whereby the rest were regulated. It is commonly supposed that the *ephah*, reduced to the Roman modius, contained four modii and a half. Now the Roman modius of grain, or flour, contained twenty libræ or pounds, consequently the *ephah* weighed ninety pounds. Dr. Arbuthnot reduces the *ephah* to three pecks three pints, English measure.

EPHETIUM, in *Botany*, a name by which some authors have called the ranunculus, or crow-foot.

EPHEBÆUM, Ἐφηβεῖον, in *Antiquity*, the place where the ephebi or youth exercised; or, as some say, where those who designed to exercise met, and agreed what kind of exercise they should contend in, and what should be the victor's reward.

EPHEBI, ἔφηβοι, among the Athenians, a designation given to their young men when they arrived at eighteen years of age, at which time they had their names entered in a public register. Pott. Archæol. Græc. lib. i cap. 9. tom. i. p. 48.

EPHEDRA, in *Botany*. See HORSE-*tail*.

EPHELLÆUM, in *Anatomy*, is the place from the hypogastrium

gastrum, or lower part of the abdomen, to the secret parts.

EPHELCIS, from ἕλκος, *ulcer*, a word used by the ancient Greek *Physicians*, sometimes for the crust of an ulcer, and sometimes for a small abrasion or bloody fragment, brought up by coughing, in an hæmoptysis.

EPHELIS, from ἐπὶ and ἥλιος, *sun*, a name used by the ancient writers on *Medicine*, for a disorder of the face, brought on by the sun and drying winds, and of the nature of what we call sun-burning. It was a certain roughness, hardness, and bad colour of the skin.

The *ephelis*, or sun-burning, is removed by an application of resin, to which a third part of fossile salt, and a little honey are added; but all these disorders, as also the unnatural colour of cicatrices, are remedied by the following preparation, ascribed to Trypho the elder:

Take equal quantities of myrobolans, croconagna, cimolian earth of a bluish colour, bitter almonds, the meals of barley and bitter vetch, dyer's weed (*struthium album*); all these are to be triturated together, and made up with the most sharp honey. With this preparation the parts affected are to be anointed at night; and the medicine carefully to be washed off the next morning. James Med. Dict. See FRECKLES.

EPHEMERA, in *Medicine*, an epithet applied to some thing that only lasts a day: particularly to a sort of fever, which terminates in the compass of twenty-four hours, called by Galen, πυρετὸς ἐφήμερος, *febris ephemera*, by the Latins, *diaria*. See FEVER.

The word, and the following one, *ephemerides*, are formed of the preposition ἐπὶ, *di*, *of*, and ἡμέρα, *diei*, *day*.

Some medical writers express themselves by *ephemera simplex vel plurium dierum*. It is, properly, an attempt of nature to ease herself of the load of a plethora, either by an absolute discharge of part of the blood by an hæmorrhage, or by resolving it into serum, and expelling it in that form, the secretory, and excretory motions, being increased beyond their natural degree. The diary fever, properly so called, lasts only twenty-four hours; but this differs in nothing, except the time of its duration, from the *ephemera plurium dierum*, which commonly lasts four days. To this it is to be added, that some authors have called the sudor Anglicus, *ephemera maligna*, a malignant diary fever, as it generally destroyed the patient in the space of one day.

The simple diary fever usually seizes the patient without any preceding shivering, and immediately is attended with a degree of heat of the flesh, which continues the same without intermission or exacerbation, till the close. This is usually not very violent, and is always attended with pains in the head, sometimes heavy and dull, sometimes pulsative and very acute. Such persons as fall into this fever, from drinking large draughts of cold liquors while they are hot, as is very frequently the case, always have a pain in the right hypochondrium. The face is red and inflated in this disease, and there is a lassitude and weariness in all the limbs, the pulse is strong and quick, the urine is of a deep orange colour, and deposits a reddish sediment.

This fever usually goes off in a moderate sweat, and sometimes, though less frequently, by a hæmorrhage at the nose. It is ever of short duration; for if it exceeds the first day, it is always terminated, at the utmost, on the fourth or fifth. There is either very little, or very bad sleep, during the whole time. The patient oft never closes his eyes at all, or, if he sleeps a little, is never sensible himself that he has slept.

The persons most subject to this fever are young men, who have much blood, and feed heartily; and such as have had any habitual discharge of blood stopped upon them, whether natural, as in the hæmorrhoidal, or menstrual discharges; or artificial, such as frequent bleeding, cupping, and the like: and those who have thrown their blood into violent emotions, by the too free use of spirituous liquors, too violent exercise, unusual watchings, long fasts by large fires, a sudden repression of sweats by cold water, or by violent passions, particularly anger.

Causes of it. The principal general causes of this fever, are a plethoric disposition, and a commotion of the blood; the accidental ones are a high diet, and sedentary life, great heat of the body from violent exercise, and from the sun in hot weather; violent sweating, or heating medicines, injudiciously administered; and sudden chilling of the body, when much heated.

Prognostics in it. The simple *ephemera*, when wholly left to itself, is of no danger, if the person be kept warm, and in a state of rest; and all that need be done in common cases, to assist nature in it, is the frequent drinking of warm diluting liquors. When it is improperly treated, or disturbed by a wrong regimen, it often has worse consequences; and, indeed, the doctor often changes this into an inflammatory or synochal fever, properly so called. It is known, that matters are properly managed, and that nature is taking her due course, if the urine and sweat are properly excreted.

Method of treatment. When the peculiar disposition of the blood, or other accidents, render this fever worse than it naturally should be, the proper course is to attemperate the violent motions of the blood with nitrous, and the fixed antimonial medicines, and occasionally, with the gentle acids, such as lemon-juice, and the like: and indeed, in all cases of this kind, the frequent use of warm and weak liquors, with lemon-juice among them, is highly to be commended. The free eruption of the sweat, by which nature attempts to ease herself of the disease, is to be promoted by the gentle sudorifics; nitre, crabs-eyes, and a small quantity of juice of lemons; just enough to saturate the alkali of the crabs-eyes, prove an excellent medicine, to be repeated in small doses every three or four hours; and toward night the sudorifics should be joined to these, such as the contrayerva-root, or the like; and when it is over, there should be given a few doses of some gentle purge, as an infusion of rhubarb and sena, or the like. Bleeding is unnecessary in this fever. Juncker's Consp. Med. p. 264.

EPHEMERA, or EPHEMERON, in *Natural History*, a name given by authors to a small fly, called by us the *day-fly*. It is an insect found about the mouths of the Rhine, and some other rivers in Germany, and seems a sort of middle species between the May-fly, common with us and bred from the cadew worm, and the libella, or DRAGON-*fly*. It has four wings, two long, and two short; two short horns, six legs, and two very long straight hairs issuing from the tail. They are seen flying about the surface of the water about mid-summer, for three days, and no longer; they eat nothing, and their only business is to drop their eggs on the surface of the water, after they have copulated. These eggs, sinking to the bottom, produce a sort of worms, or maggots; these soon hollow themselves cavities in the clay, where they remain three years, growing every year about an inch in length. When the worm is come to its full growth, it rises to the surface of the water about six o'clock in the morning, and there issues from it this fly, which lays its eggs, and dies about six o'clock the same night; so that the life of the creature in the fly-state is only about five hours. Swammerdam, Hist. Ins.

Though Swammerdam says, that the life of this creature is no more than five hours, yet his own account plainly shews that it really lives three years; for it is certainly as much alive in the worm state as when afterwards it becomes a fly. Baker's Micr. 1743. p. 305.

EPHEMERA, in the Linnæan system, makes a distinct genus of the *neuroptera* order, distinguished by two gibbous protuberances above the eyes, erect wings, and bristly tail. He enumerates eleven species of this genus, distinguished by their different colours, and the number of hairs in their tail; some having two, and others three.

EPHEMERA, is also applied among *Botanists*, to a kind of flowers which open and expand themselves at sun-rising, and wither or close up again at his setting. Such are the dent-de-lion, vulgarly dandelion, and diverse others.

EPHEMERIDES, in *Astronomy*, tables calculated by astronomers, shewing the present state of the heavens for every day at noon; that is, the places wherein all the planets are found at that time.

It is from these tables that the eclipses, conjunctions, and aspects of the planets, are determined; horoscopes, or celestial schemes, constructed, &c.

We have *ephemerides* of Origan, Kepler, Argoli, Heckerus, Mezzarachis, Wing, De la Hire, Parker, &c. S. Cassini has calculated *ephemerides* of the fixed stars medicea, or satellites of Jupiter, which are of good use in determining the longitude.

In England the Nautical Almanac, or Astronomical *Ephemeris*, published annually by anticipation, under the direction of the commissioners of Longitude, is the most considerable. See ALMANAC.

In France, celestial *Ephemerides* have been published by M. Desplaces, every ten years, from 1715 to 1745: and were afterwards continued by the abbé Caille, with many additions; of which an account may be seen in the History of the Academy of Sciences for 1743. The Academy of Sciences have likewise published annually, from the beginning of the present century, a kind of *ephemeris*, under the title of Connoissance des Temps.

EPHEMERUM. See SPIDER-*wort*.

EPHESIA, in *Mythology*, a feast instituted at Ephesus, in honour of Diana.

EPHESTIA, in *Mythology*, a feast celebrated in honour of Vulcan, in which three young *lads run for a prize*.

EPHESTRIA, were feasts celebrated at Thebes, in honour of Tyresias.

EPHESUS, *temple of.* See DIANA.

EPHETÆ, of ἐφημι, *I send forth*, in *Antiquity*, a sort of magistrates among the Athenians, instituted by king Demophoon, to take cognizance of murder, manslaughter, and chance-medley.

Their number was one hundred, whereof fifty were Athenians, and fifty Argians: they were not admitted to the post till upwards of fifty years of age. Draco new modelled it, excluded the Argians out of it, and made it to consist of fifty-one Athenians, each above fifty years of age: Ubbo Emmius de Rep. Athen. says, he transferred to them part of the jurisdiction of the Areopagites. See AREOPAGUS.

EPHIALTES, of ἐπι and ἁλλομαι, *I leap.* See INCUBUS.

EPHIDROSIS, from ἐφ-ἱημι, *I sweat*, in the *Medical Writings of the Ancients*, a word used to express a sweat, sometimes slight, and not critical; and at others, a symptomatic one, appearing only on the head, neck, and breast. These are both bad symptoms in many diseases, though they are often mistaken by the injudicious for good signs, and forwarded by hot medicines, to the destruction of the patient. See SWEAT and SWEATING.

EPHIPPIA, of ἐπι and ἱππος, *horse*, denoted certain cloths or housings, which were fastened on a horse by a girth or surcingle, in ancient Greece, before the use of saddles were known. They were composed of different materials as leather, cloth, and the skins of wild beasts, and sometimes adorned with gold, silver, and precious stones. Bevereger's Art of Horsemanship, vol. i. p. 41.

EPHIPPITES. See HIPPODROMUS.

EPHIPPIUM. Εφιππιον, in *Anatomy*, a part of the ENCEPHALOIDES, called also *sella equina* and *sella turcica*.

EPHOD, אפד, derived from אפד, *aptum, to clothe*, a facerdotal garment, in use among the ancient Jews, supposed to have been a kind of linen alb, or surplice, wore by persons of distinction, of various characters; the same with what the Latins call *super-humerale*.

It is very hard to say precisely what the *ephod* was; and there is room enough for the interpreters to be divided about it. The only point they are agreed upon is, that it was an upper garment worn over all the rest, immediately under the pectoral or breast-plate. Some hold it had sleeves, others deny it. The generality agree that it was very short, though some maintain that it hung down to the feet behind.

There were two kinds of *ephods*; the one, common to all who assisted in the temple, being only made of common linen, mentioned in the first book of Samuel, ii. 18; the other, peculiar to the high-priest, mentioned Exod. xxviii. 6. 15. to be made of gold, of blue, and of purple, of scarlet, and fine twined linen, with cunning work; having two shoulder-pieces, with a curious girdle of the same matter, whereon were two onyxes, with the names of the children of Israel engraved thereon.

It is also expressed in the second book of Samuel, vi. 14. that upon the removal of the ark of the covenant from the house of Obed-Edom, David danced for joy, girt with a linen *ephod*; whence some authors have concluded, that the *ephod* was also a regal garment, worn on solemn occasions.

EPHORI, Εφοροι, magistrates established in ancient Sparta, to balance and check the power and authority of the kings; as at Rome, there were tribunes created to controul the power of the consuls.

The word is formed of the Greek, εφορω, *intueor*, formed of the preposition επι, and the verb οραω, *to see*, whence οφρυς, q. d. *inspector, overseer*.

Lycurgus being sensible that a perfect understanding between the prince and the people, was the basis and foundation of both their happiness, to maintain that good understanding, established *ephori*, or inspectors, as a kind of mediators, who should have an eye to the measures and conduct of both sides, and preserve so equal a balance between them, that the regal power should never decline into severity and tyranny, or the liberty of the people run into licence and rebellion.

This is the account of their institution given by Herodotus and Xenophon. Her. lib. i. Xen. de Rep. Lacedæm.

The authority of the *ephori* was very great: they presided in popular assemblies, collected their suffrages, declared war, made peace, treated with foreign princes, determined the number of forces that should be raised, appointed the funds to maintain them, and distributed rewards and punishments in the name of the state: they likewise held a court of justice, enquired into the behaviour of all magistrates, inspected the education and conduct of youth, had a particular jurisdiction over the *helotes*, and by degrees drew the whole administration into their own hands. On certain occasions they expelled, and even put to death the kings, and abolished or suspended the power of the other magistrates, calling them to account at pleasure. Agesilaus, in the height of all his conquests, which even struck terror on the great king of Persia, stopped, and turned back, out of deference to the *ephori*, when they recalled him.

Some authors deny, that the *ephori* were established by Lycurgus, dating their origin 130 years after the time of that legislator.

Thus Plutarch, in his life of Cleomenes, affirms their institution to Theopompus, king of Sparta, which is also confirmed by the authority of Aristotle. Polit. lib. v. The *ephori* were five in number, and annually chosen by the people out of their own body. The year was denominated from the first election of these magistrates, and the Lacedæmonian armies took their names from the principal *ephori*, as those of Athens did from their first ARCHON.

EPHYDOR, Εφυδωρ, in *Antiquity*, an officer in the Athenian courts of justice, who was to provide the plaintiff and defendant with equal water hour-glasses. When the glass was run out, they were not permitted to speak any farther; and therefore we find they were careful not to lose or mispend one drop of their water. Whilst the laws quoted by them were reciting, or if any other business happened to intervene, they gave order that the glass should be stopped. Pott. Archæol. Græc. lib. i. cap. 21. lib. ii. p. 118.

EPHYDRUM, Εφυδρον, in *Botany*, a name given by some of the Greek writers, to the plant now called *equisetum*, or HORSE-*tail*.

EPIALOS, from επιος, *gentle*, and αλγ, *fever*, in the *Medical Writings of the Ancients*, the name of a fever, in which the patient labours under a preternatural internal heat, while he at the same time shivers with cold. It has by some been called the *shivering-fever*; and the Romans named it *quercera*. Galen says it proceeds from a putrefied acrid phlegm. The word is, by some, also applied to any gentle fever, or feverish complaint; and by others, to the cold or shivering fit preceding a fever. Hippocrates calls by this name that peculiar fever which attends young women, whose menses are stopped by taking cold, or other accidents.

EPIBATÆ, Επιβαται, among the Greeks, marines or soldiers who served on board the ships of war. They were armed in the same manner as the land-forces, only that more of them wore full or heavy armour. Pott. Archæol. Græc. tom. iii. p. 140.

EPIBATERION, a poetical composition, in use among the ancient Greeks. When any person of condition and quality returned home after a long absence or journey, into another country, he called together his friends and fellow-citizens, and made them a speech, or rehearsed them a copy of verses, wherein he returned solemn thanks to the immortal gods for his happy return; and ended with an address by way of compliment to his fellow-citizens.

These verses made what the Greeks call επιβατηρια, *epibaterion*, of επιβαινω, *I go abroad*. At going away they had another, called *apobaterium*.

EPIC *poem*, an heroic poem, or a poem reciting some great and signal transactions of a hero; called also *epopœia*.

Such are the Iliad and Odyssey of Homer, the Æneid of Virgil, the Gierusalemme of Tasso, the Paradise Lost of Milton, and the Henriade of Voltaire, which are the principal poems of the *epic* kind.

An *epic* poem, according to Bossu, is a discourse invented with art, to form the manners, by instructions disguised under the allegory of an important action related in verse, in a probable, entertaining, and surprising manner.

The *epic* poem is distinguished from comedy, in that the action of the latter is not important, nor is related by the poet, but acted by the persons introduced for that purpose; which circumstance, likewise, distinguishes it from tragedy. It differs also from tragedy in the event, or conclusion; which, in the latter, is generally unfortunate, but never so in the former.

Nor is it a philosophical poem, as that of Lucretius, or the Creation of sir R. Blackmore; nor a treatise of agriculture, or the like, as the Georgics of Virgil; those poems not being intended to form the manners: beside that the instructions they contain are naked, simple, and direct, without any disguise or allegory. Which second circumstance likewise distinguishes it from a treatise of morality, written in verse; or a simple history in verse, as the Pharsalia of Lucan, the Punic War of Silius, or the Civil Wars of Sam. Daniel; add, that its being confined to one important action, distinguishes it from a poem which relates all the actions of a person's life, as the Theseid and Achilleid of Statius, which are what we properly call *heroic poems*.

M. de la Motte, indeed, in his controversy with Madam Dacier,

Dacier, on the subject of Homer, maintains, that the whole life of a hero may justly be made the subject of an *epic* poem: and even that the Lutrin of M. Boileau might pass for an *epic* poem; but he seemed afterwards to return to the common sentiment. In effect, the question is not as to the sense which may be annexed to the words *epic poem*, but the sense which custom has actually annexed to them.

If we had only regard to the etymology of the word *epic*, (of ἔπος, *verse, poetry*, from εἶπον, *dico, I speak, relate,*) all poems wherein the poet speaks or rehearses things himself, without making the persons of his poems speak except at second hand, as he relates what they spoke on this or that occasion, would be properly *epic* poems; and so there is not an epigram, sonnet, or madrigal, but would come under that denomination: but this were wild.

In effect, the term *epic* poem is only attributed to a composition whose subject is great, instructive, and serious; that only comprehends one single principal event, to which all the rest refer; which principal action is to be terminated in a certain space of time, ordinarily about a year. It is true, all this is arbitrary; but the sense of all words is so too; and in matters of language we must be guided by custom.

If M. de la Motte had only pretended, that one might make a fine instructive poem on the whole life of a hero, or an agreeable and diverting poem on some humorous adventure, all the world would have been on his side. But it is enough that custom has not thought good to apply the term *epic* either to subjects of too much extent, and that are crouded with two many incidents not-way connected together; or to burlesque poems, as the Batrachomomachia of Homer, the Secchia Rapita of Taffoni, the Défaite de Dulot, the Lutrin of Boileau, the Hudibras of Butler, the Rape of the Lock of Mr. Pope, or the Dispensary of Dr. Garth.

The *epic* poem, then, as appears from what was above observed, bears a relation or analogy to four things, history, morality, fable, and poetry. To *history*, as both of them relate one or more actions; but then the actions of history are singular, so that the epopœia is no history, nor kind of history.

To *moral philosophy*, as both of them consist of instructions for forming the manners; but the action and allegorica distinguish it herefrom.

But it relates entirely to poetry and fable, as being strictly a poem and a fable.

The nature of the *epic* poem is finely drawn by the great critic above mentioned: the *epic* poets, says father Bossu, have done that with regard to morality which the ancient heathen divines did with regard to divinity. The too great diversity of divine actions and perfections, so very disproportionate to our comprehension, obliged the latter to divide a single idea of a simple essence, God, into several persons, to whom they attributed several names, Jupiter, Juno, Neptune, &c. And, on the contrary, the nature of moral philosophy, which never prescribes rules for particular things, led the poets to collect into one single idea, or into one and the same person, and one apparently singular action, whatever of that kind was found in different persons and different actions.

Thus Aristotle, ὁ τραγικὸς ποιητὴς ἱστορικός, &c. Poetry, says he, teaches moral philosophy, not by relating only, in the manner of an historian, what Alcibiades, for instance, did or suffered; but by proposing what some person, named as the poet thinks fit, would probably or necessarily have done on the like occasion: and thus it is that he shews either the unhappy consequences usually attending imprudent schemes or ill actions; or the reward of good actions, and the satisfaction resulting from a design laid in virtue, and conducted with prudence. So that in the *epic* poem, according to Aristotle's sentiment, the persons and actions, however named, are all to be feigned, allegorical and universal, not historical and singular.

But the poets, thus taking on them the office of moral philosophers, did not cease to be divines. On the contrary, their morality itself frequently obliges them to introduce the deity in their works; as the knowlege, fear, and love of God, are the first and most solid foundations of all morality. The presence of the divinity, and the share so august a personage was supposed to have in the action, obliged the poet to make the action great and important, and to have it transacted by kings and princes. The fame likewise obliged them to think and speak in a manner elevated above the common pitch of men, and equal, in some measure, to the dignity of the divine persons introduced. To which end serves the poetical and figurative language, with the majesty of heroic verse. Add, that as so much of the divine and miraculous might ruin the probability, they were hereby obliged to have recourse to several rules to maintain the fame.

Thus much the poets were driven to by the substance of the things they had chosen for the matter of their poems and instructions. The manner of delivering them usefully and methodically, obliged them to several other necessary rules.

The *epic* poem is intended more for the manners and habits, than for the passions. These latter rise all at once, and their violence is but of short duration; but the habits are more calm and impressed, or quitted more leisurely. Consequently, the *epic* action could not be included in the space of a day, as that of the theatrical. A longer time was necessary than is required for tragedy, which is altogether for the passions.

This distinction has introduced great difference between tragedy and *epic* poetry. The tragic violence requires a more lively and animated representation than a mere recital: accordingly, it is wholly thrown into action, and the poet never speaks at all, as he does in the epopœia, where there are no actors. An *epic* poem, properly so called, should be written in honour of the country and religion of the author, between which and the hero there is a near relation, and therefore he ought at least to come off in triumph. See further of the nature of the *epic* poem under FABLE. For its matter, see ACTION. For its form, see NARRATION. For its versification, see HEXAMETER. See also MANNERS, CHARACTERS, MACHINE, &c.

EPICALYMMA, a word used by some of the *Old Writers on Physic*, and not well understood by their commentators.

EPICARPIUM, Ἐπικάρπιον, formed of ἐπὶ, *on*, and καρπὸς, *wrist*, in *Medicine*, a kind of remedy, usually in form of a cataplasm or plaster, consisting of sharp, penetrating ingredients, as garlic or onion, spider's-web, hellebore, camphor, Venice treacle, &c. applied round the wrist, at the beginning of the access of a fever, to prevent the growth of the same.

EPICAUMA, from καίω, *I burn*, in *Medicine*, a crusty ulcer that sometimes happens to the black of the eye.

EPICEDION, Ἐπικήδιον, formed of ἐπὶ, *upon*, and κῆδος, *funeral*, in the *Greek and Latin Poetry*, a poem, or poetical composition, on the death of a person.

At the obsequies of any man of figure, there were three kinds of discourses usually made; that rehearsed at his bustum or funeral pile, was called *nenia*; that engraven on his tomb *epitaph*; and that spoken in the ceremony of his funeral, *epicedion*. We have two beautiful *epicedions* in Virgil, that of Euryalus, and that of Pallas.

EPICERASTICS, Ἐπικρατικὰ, formed of ἐπὶ and κρατῶ, *I moderate*, in *Medicine*, remedies, which, by their temperate moisture, soften the acrimony of a humour, and assuage the painful sensation of a part irritated or afflicted by it; such are the roots of althæa, mallows, liquorice; leaves of lettuce, mallows, water-lily, purslain; the seeds of flax, poppy, &c. See EMOLLIENTS.

EPICHIREMA, Ἐπιχείρημα, in *Logic*, an argumentation, consisting of four or more propositions, some whereof are proofs of others.

Thus, that oration of Cicero for Milo may be reduced to the *epichirem*: "Those who way-lay a man to kill him, "it is lawful for him to kill, as is allowed by the laws of "nature and nations, and by the practice of the best "men; but Clodius way-laid Milo with that view, as "appears from his forming an ambuscade before his "country house, and from his provision of weapons, "soldiers," &c. Therefore it was lawful for Milo to kill Clodius.

EPICHIROTONIA, among the Athenians. It was ordained by Solon, that once every year the laws should be carefully revised and examined; and if any of them were found unsuitable to the present state of affairs, they should be repealed. This was called ἐπιχειροτονία τῶν νόμων, *from the manner of giving their suffrages, by holding up their hands*. See a farther account of this custom in Potter. Archæol. Græc. lib. i. cap. 20. tom. i. p. 142.

EPICHORDIS, from χορδὴ, *an intestine*, in *Anatomy*, a name given by some to the mesentery.

EPICLEROS, Ἐπίκληρος, among the Athenians, a daughter that had no brothers, and therefore inherited her father's whole estate. See EPIDICASIA.

EPICŒNE, Ἐπίκοινον, in *Grammar*, a term applied to nouns, which, under the same gender and termination, mark, indifferently, two kinds of sexes. See GENDER.

Such, in Latin, is, *aquila, vespertilio*, &c. which signify equally a male or female eagle or bat.

Grammarians distinguish between *epicene* and common. A noun is said to be common of two kinds, when it may be joined either with a masculine or a feminine article; and *epicene*, when it is always joined to some one of the two articles, and yet signifies both genders.

EPICOLIC *regions* (from ἐπὶ, *supra, upon*, and κόλον, the *gut*,

gut, fo called) a name given by Dr. Gliffon to that fpace on both fides, over the colon.

EPICRANIUM, in *Anatomy*, a name given by Albinus to the fleſhy covering of the head, divided by authors into ſeveral different muſcles. The head is covered with a thin coat: the hinder parts of this coat are called the occipital muſcles, and the fore part the frontal muſcles.

EPICRASIS, in *Medicine*, is a gradual evacuation of ill humours in the blood.

EPICRISIS, Ἐπικρισις, in *Rhetoric*, a clear and brief declaration of the ſpeaker's judgment concerning the ſubject in hand. Thus, *ego ſic ſtatuo, in optimo imperatore quatuor hæc res ineſſe oportere, &c.* Voſſ. Rhet. lib. vi. p. 495.

EPICUREANS, a ſect of ancient philoſophers, who adhered to the doctrines and opinions of Epicurus.

Epicurus was an Athenian, and the ſon of Neocles, born in the third year of the 109th Olympiad, and conſequently 341 years before Chriſt. He ſpent his youth partly in the iſle of Samos, and partly at Teos, and did not return to Athens till he was eighteen years old: whence he removed at the age of twenty-three to Colophon, and ſojourned in ſeveral places before he fixed again at Athens, in the thirty-ſeventh year of his age. He was the diſciple of Pamphilus the Platonic; and he ſtudied the writings of Anaxagoras, Archelaus, Metrodorus and Democritus. He began to form his ſchool at Mitylene and Lampſachus about the thirty-ſecond year of his life; though he afterwards removed to Athens, where he philoſophized chiefly in his garden, teaching a great number of diſciples, who flocked to him from all the cities of Greece and Aſia, and even from Egypt, and who lived in common with their maſter. His own life was exemplary, though it has not eſcaped calumny. He died of the ſtrangury at ſeventy-two years of age. His memory was greatly reſpected by his followers, and his doctrine reverenced as an oracle: and as long as learning flouriſhed in Greece, and Rome was preſerved from the Barbarians, the ſchool and diſcipline of Epicurus continued eminent.

His birth-day continued to be obſerved in Pliny's time; and the whole month in which he was born was obſerved as a perpetual feſtival. Cicero de Fin. lib. v. init. and Plin. lib. xxxv. cap. 2.

The noble poet Lucretius, who has given us a beautiful ſyſtem of *Epicureaniſm* in fine Latin verſe, prefers its father Epicurus to all other philoſophers, whom, he makes no ſcruple to ſay, he obſcured as much as the ſun does the other ſtars. It is ſaid he firſt taught grammar; ſtill, upon reading Democritus's books, he began to apply himſelf to philoſophy.

From Democritus he learned the doctrine of atoms, or corpuſcles, which he afterwards made the baſis of his phyſics. Clem. Alexand. Strom. 6. advances, that Epicurus ſtole his chief doctrines from Democritus: but it is certain he greatly improved and illuſtrated them. Diog. Laertius aſſures us, he compoſed an infinite number of volumes. Diog. Laert. in Procem. lib. x. p. 26. This philoſophy conſiſted of three parts; *canonica*, κανονικὸν; *phyſica*, φυσικὸν; and *ethica*, ἠθικὸν, which he explained briefly in three epiſtles.

The firſt, as Laertius relates, was about the canons, or rules of judging; wherein, rejecting the uſe of logic, he eſtabliſhed the ſenſes, paſſions, and anticipations, as the criterions, or judges of truth.

The canons of ſenſe are the following four: ſenſe is never deceived; and therefore every ſenſation, and every perception of an appearance is true. Opinion ſucceeds ſenſe, and is ſuperadded to ſenſation, and capable of truth or falſhood: all opinion atteſted, or not contradicted by the evidence of ſenſe, is true, and the contrary opinion is falſe. The canons of anticipation are alſo four; all anticipation, which is in the mind, depends on the ſenſes, by incurſion, proportion, ſimilitude, or compoſition. Anticipation, or prenotion, is, as it were, the definition of the thing, without which we cannot enquire, doubt, think, nor ſo much as name any thing. Anticipation is the principle in all diſcourſe, as being that to which we have regard, when we infer that one thing is the ſame or different, joined with or diſjoined from another; that which is not manifeſt ought to be demonſtrated out of the anticipation of a thing that is manifeſt. The canons of paſſion likewiſe are four: all pleaſure, which hath no pain in it, is to be embraced; all pain, that hath no pleaſure with it, is to be ſhunned; all pleaſure, which hindereth a greater pleaſure, or procureth a greater pain, is to be ſhunned; all pain, which putteth away a greater pain, or procureth a greater pleaſure, is to be embraced.

In the ſecond, he laid down atoms, ſpace or vacuum, and gravity, as the firſt principles of all things. The univerſe, he taught, conſiſted of atoms or corpuſcles, of various forms, magnitudes, and weights, which having been diſperſed at random through the immenſe inane, or ſpace, fortuitouſly concurred into innumerable ſyſtems or worlds, which were thus formed, and afterwards, from time to time increaſed, changed, and diſſolved again, without any certain cauſe or deſign; without the intervention of any deity, or the interdiance of any providence. See ATOMICAL and CORPUSCULAR *philoſophy*.

Not that he denied the exiſtence of a God; on the contrary, he aſſerted it; but he thought it beneath the majeſty of the Deity to concern himſelf with human affairs.

Thus Epicurus denied a providence, and every kind of natural and moral adminiſtration of the Deity. But though he adopted the notion of Leucippus and Democritus, concerning the formation of the world by the fortuitous concourſe of atoms, he rejected the opinion of FATE. In this particular, he abandoned the ſyſtems of atoms, and the neceſſitating deſtiny, ariſing from the external and innumerable laws of motion, to which Democritus aſcribed the production of the world, and maintained the liberty of human actions. But nothing can be more abſurd than his reaſoning on this ſubject. He gave his atoms a motion of deſcription, wherein he eſtabliſhed the ſeat, ſource, and principle of free actions; pretending, that by this means, there were events independent of fatal neceſſity. Before him, no other motion was admitted in atoms but that reſulting from their weight and their reflexion; the firſt of which was always in perpendicular lines, and *in vacuo* ever the ſame; nor was it changed, except when one atom ſtruck againſt another. Epicurus, on the contrary, ſuppoſed, that even in the midſt of the vacuum atoms did ſomewhat decline from the direct line; and hence, he ſaid, proceeded liberty. Thus alſo he accounts for the concourſe of various atoms in the production of the world. Cicero has expoſed the abſurdity of this notion of declination in his book De Fato, cap. 10. See alſo de Fin. lib. i. cap. 6.

The theology of Epicurus was not only eſſentially defective in his diſbelief of providence, but likewiſe in his notion of the mortality of the ſoul, and rejection of a future ſtate. Death, according to his ſyſtem, was a mere privation of ſenſe; when the body was diſſolved, the ſoul was diſſipated, had no longer the ſame faculties, nor was any longer moved, nor had any ſenſe. The ſoul was diſſipated into the principles and little bodies of which its contexture was compoſed; and he argued this diſſipation of the ſoul from its being compounded, and having a beginning. Motheim has, therefore, juſtly obſerved, that of all the philoſophers, the *Epicureans* enjoyed the greateſt reputation, and had undoubtedly the greateſt number of followers, becauſe their opinions tended to encourage the indolent ſecurity of a voluptuous and effeminate life, and to baniſh the remorſe and terrors that haunt vice, and naturally incommode the wicked in their ſenſual purſuits. Eccl. Hiſt. vol. i. p. 138. 8vo.

As to ethics, his firſt principle, or the ſupreme felicity of man, he held, was pleaſure: which ſome, as hereafter obſerved, underſtand of mental, and others of carnal pleaſure.

The *Epicureans* have, in all ages, been decried for their morals, and their attachment to the pleaſures of ſenſe: ſeveral authors, particularly Cicero among the ancients, and Gaſſendus among the moderns, have endeavoured to vindicate them from this charge; by ſhewing that the pleaſure wherein their maſter Epicurus places the ſummum bonum, or ſupreme happineſs of this life, was not any ſenſual, or brutal pleaſure, but a contentment, and tranquillity of mind, exempt from all tumultuary paſſions, &c.

This opinion ſeems juſt, and well-grounded; but, without entering into the queſtion, which Gaſſendus, Du Rondel, and others, have exhauſted, it is certain, that in the common uſe of the word, *Epicurean* is underſtood to ſignify an indolent, effeminate, and voluptuous perſon, who only conſults his particular and private pleaſure, without concerning himſelf with any thing ſerious.

In effect, there were always two kinds of *Epicureans*; the *rigid*, and *remiſs*: the rigid *Epicureans* were thoſe ſtrictly attached to the ſentiments of Epicurus, who placed all their happineſs in the pure pleaſures of the mind, reſulting from the practice of virtue. The looſe or remiſs *Epicureans*, taking the words of that philoſopher in a more groſs ſenſe, placed all their happineſs in pleaſures of the body, in eating, drinking, loving, &c. The former kind, who were the genuine *Epicureans*, called the others the *ſophiſts of their ſect*. Stanley's Hiſt. of Philoſophy, part xiii. Gaſſendus de Vita & Moribus Epicuri. Bayle, art. Epicurus.

EPICYCLE, in *Astronomy*, a circle, whose centre is on the circumference of another circle which bears it, and which for that reason is called its *deferent*.

The word is formed of the Greek επι, *upon*, and κυκλος, *circle*, q. d. *a circle on a circle*.

As astronomers invented an eccentric circle to solve the apparent irregularity of the planets, and their different distances from the earth; they likewise invented a little circle to solve the stations and retrogradations of the planets: this circle, which they call *epicycle*, has its centre in the circumference of another greater, which is the eccentric of a planet.

In this eccentric the centre of the *epicycle* moves; carrying with it the planet fixed in its circumference, the centre of the planet, all the way, moving regularly along the circumference of the *epicycle*, when downwards, according to the order of the signs, and when upwards, contrary to it.

The highest point of the *epicycle* is called the *apogee*, and the lowest the *perigee*.

The great circle, in whose circumference the centre of the *epicycle* is placed, is also called the *deferent of the epicycle*, whose centre is in the orbit of the earth, according to the hypothesis of Copernicus; but of that of Ptolemy, who supposed the heavens solid, the *epicycle* was a sphere, which revolved with the moon, of the thickness allowed its heaven or orbit; and which sometimes shewed it higher, and sometimes lower. See *Ptolemaic* SYSTEM.

"The astronomers, who deny the motion of the earth, "in order to render the phenomena of the motions of "the planets more consistent with the motion of the sun, "have allixed the orbit of the earth, as an *epicycle* to the "orbit of the planets; so that the planet should proceed "in an *epicycle*, while it is carried through its orbit round "the sun; but this is far from answering their expecta-"tions." Wolf. Elem. Math. tom. ii. p. 501.

"Ricciolus, though a zealous enemy of the motion of "the earth, could not make any astronomical tables that "should but tolerably agree with observation, without "supposing the earth to move; and, though he called in "all the foreign and forced assistances of changeable *epi-"cycles* liable to continual increase and decrease, and va-"riously inclined to the ecliptic." De Chales Astron. Reform. lib. x. cap. 1. fol. 353, &c.

Epicycles have likewise been introduced by Dr. Halley and Mr. Machin, to account for the inequalities of the moon's motion. See MOON.

EPICYCLOID, in *Geometry*, denotes a curve generated by the revolution of a point of the periphery of a circle, along the convex or concave part of another circle.

A point of the circumference of a circle, proceeding along a plane in a right line, and at the same time revolving on its centre, describes a cycloid.

And if the generating circle, in lieu of moving on a right line, moves along the circumference of another circle, whether equal or unequal, the curve described by any point in its circumference is called an *epicycloid*.

If the generating circle proceeds along the convexity of the periphery, it is called an *upper*, or *exterior epicycloid*: if along the concavity, a *lower*, or *interior epicycloid*.

In an *epicycloid*, the part of the circle the generating point moves along, is called the *base of the epicycloid*: thus in *Tab. Geom. fig.* 58. DB is the base of the *epicycloid*, V its vertex; VB its axis; DPV half of the *exterior epicycloid*, made by the revolution of the semicircle VLB (which is called the *generant*) along the convex side of the base DB; as DPU is the *interior epicycloid*, formed by the generant's revolving along the convex side of the base.

The length of any part of the curve, which any given point in the revolving circle has described from the time it touched the circle whereon it revolved, is to double the verse line of half the arch which all that time touched the quiescent circle, as the sum of the diameters of the circles to the semidiameter of the quiescent circle: provided the revolving circle moves upon the convex side of the quiescent circle; but if upon the concave side, as the difference of the diameters to the semidiameter.

Dr. Hailey gives us a general proposition for the measuring of all *cycloids* and *epicycloids*: thus, the area of a cycloid, or *epicycloid*, either primary, or contracted, or prolate, is to the area of the generating circle; and also the areas of the parts, generated in those curves, to the areas of analogous segments of the circle; as the sum of double the velocity of the centre, and velocity of the circular motion, to the velocity of the circular motion. The demonstration hereof, see in Phil. Trans. N° 218.

Spherical epicycloids are formed by a point of the revolving circle, when its plane makes an invariable angle with the plane of the circle on which it revolves. Messrs. Bernoulli, Maupertuis, Nicole, and Clairaut, have demonstrated several properties of these *epicycloids*, in Hist. Acad. Sc. for 1732.

EPICYEMA, from κυω, *I conceive*, a word used by Hippocrates to signify a foetus, or a false conception, or mole coming on after the conception of a former or regular foetus.

EPIDAURIA, Επιδαυρια, in *Antiquity*, a festival celebrated by the Athenians in honour of Esculapius.

EPIDELOS, a word used by Hippocrates, for a youth in the time of his growth, from the age of seven to that of fourteen. The same author also uses it in a very different sense, expressing by it the observable days in a disease, such as the fourth, eighth, and eleventh, which indicate what sort of crisis is to be reasonably expected on the great critical day.

EPIDEMIA, Επιδημια, in *Antiquity*, feasts of Apollo at Delphos, and Miletus; and of Diana at Argos.

These feasts bore the name *epidemia* (from επι, *in*, and δημος, *people*) because these gods were imagined to be present on those days among the people. Accordingly, on the last day of the *epidemia* they sung an hymn called ανεπιστητικος, to bid them adieu, and let them forwards on their journey.

As those gods could not be every where, and yet were honoured in many different places, there were times allowed them to pass from one place to another, to receive the vows of their adorers. See Scaliger, Poet. lib. iii. cap. 114.

EPIDEMIA were also private festivals, and times of rejoicing, when a friend, or relation, had returned from a journey. Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

EPIDEMIC, Επιδημιος, denotes a general or spreading disorder, as a plague, arising from some corruption or malignity in the air, which seizes great numbers of people in a little time.

The word is Greek, formed of επι, and δημος, *populus*, *people*; such diseases running among all kinds of people, of whatever age, sex, quality, &c. as arising from a common or general cause.

The Latins call them *popularei morbi*, *populor diseases*: in opposition to those called *sporadici*, which are only here and there, as arising from private or particular causes. See SPORADIC.

Epidemic diseases differ from endemial; which imports diseases peculiar to some particular country, region, or people; whereas *epidemic* diseases are such as are peculiar to certain seasons.

Pertinent to the present subject are the observations of the celebrated Boerhaave on *epidemical* diseases. We must remark, says this author, that though every particular disease of the fluids in various *epidemical* constitutions appear, to inattentive observers, the same with regard to their names, signs, and, in some measure, in their consequences; yet the same diseases appearing in one *epidemical* constitution, differ exceedingly from those produced in another, with respect to their obscure natures; their appearances not observable, except by the judicious; the various times of their increase, state, coction, crisis, effect, event, and method to be pursued in their cure. Hence, it is evident that they require a different administration of the non-naturals, different treatment and medicines. This variety, however, in *epidemical* distempers, is so obscure, that physicians have not yet been able to deduce it from any abuse of the non-naturals; and yet there are many circumstances that render it highly probable, that the causes reside in the air, but depend more upon the inexplicable variety of exhalations contained therein, which by their mixture with the fluids of the body, or their stimulus, injure the human machine, than upon any change in the sensible qualities thereof. But it is very surprising, that these *epidemical* disorders should be principally propagated by contagion, received from one, by another person unaffected. Upon the invasion of any unknown *epidemical* distemper, the physician will receive some information with respect to the cure; first by reducing the distemper to some more known species, which it most resembles; secondly, by observing its tendency at the vernal and autumnal equinoxes, at which seasons it is generally most prevalent; thirdly, by attending to the spontaneous phenomena, which precede, accompany, or follow, the recovery or death of the patient, and the different states of the disorder; fourthly, by diligently remarking the benefit or injury received, from whatever the patients are unavoidably obliged to do, as from whatever is taken into, or discharged out of the body; fifthly, by comparing the cases of many patients labouring under the distemper, at the same time; sixthly, by abstaining from all remedies which are dubious, which exasperate, and induce a considerable change in the humours, and thereby obscure the genius of the disease.

From these circumstances, duly attended to, the curative indication may be discovered. See *Pestilential* DISEASES.

EPIDENDRA, from ἐπι, upon, and δενδρον, tree, in *Natural History*, a word used by Sir Hans Sloane, and some other authors, to express those plants which grow upon others, such as the MISLETOE, which grows upon the apple-tree, &c. These are more commonly distinguished by the name of parasitical plants. See DODDER.

EPIDENDRUM, in *Botany*. See VANILLA.

EPIDERMIS, in *Anatomy*, the cuticle, or scarf-skin.

The word is formed of the Greek ἐπι, *on*, *over*, and δερμα, *skin*.

Some hold the *epidermis* to be formed of the excrements of the *dermis*, or true skin. Hippocrates is of opinion, it is engendered by cold; as on blood, broth, or the like, when cold, we see a pellicle formed.

But it is now paft doubt, that it is produced at the fame time, and after the fame manner, with the other parts: it being found in foetuses of all ages, in the womb: it has neither vein, arteries, nor nerves; whence it is infenfible. See CUTICULA.

EPIDICASIA, ἐπιδικασια, among the *Athenians*, Daughters inheriting their parents eftate, were obliged to marry their nearefl relation; which gave occafion in perfons of the fame family to go to law with one another, each pretending to be more nearly allied to the heirefs than the reft. The fuit was called ἐπιδικασια: *Lysias* and the virgin, about whom the relations conteffed, ἐπιδικος. Potter. Archæol. Græc. lib. i. cap. 24. tom. i. p. 147.

EPIDIDYMIS, in *Anatomy*, a little round body, on the back of each TESTICLE; called alſo PARASTATA.

The word is formed of επι, *upon*, and διδυμος, *twin*, *gemine*. See FISTULA.

EPIDOTES, from ἐπιδιδωμι, *I cauſe to grow*, in *Mythology*, deities which were ſuppoſed to preſide over the growth of infants.

EPIDROMUS, of επι and δρομος, *courſe*, in the *Ancient Shipping*, a ſail near the ſtern, which was the largeſt but one in the ſhip.

EPIGÆA, *Trailing Arbutus*, in *Botany*, a genus of the *decandria monogynia* claſs. Its characters are theſe: the flower hath a double empalement, the outer compoſed of three, and the inner of one leaf, divided into five parts; the flower is of a falver-ſhape, and hath ten ſlender ſtamina of the length of the tube. In the centre is ſituated a globular germen, which afterward becomes a depreſſed five-cornered fruit, with five cells, containing ſeveral ſeeds. There is one ſpecies, a native of North America.

EPIGASTRIC *region*, in *Anatomy*, is a name given to the upper part of the ABDOMEN, reaching from the cartilago xiphoides, almoſt to the navel.

It is uſually divided into three parts: the ſides, or lateral parts, called *hypochondres*; and the middle, the *epigaſtrium*.

There are alſo two *epigaſtric* veins, and as many arteries. The arteries are branches of the iliac external arteries: the veins diſcharge themſelves into the iliac external veins. See *Tab. Anat. Angeiol.* *fig.* 1. N° 57. *fig.* 6. N° 3.

EPIGASTRIUM, of επι, upon, and γαστηρ, *belly*, in *Anatomy*, the middle part of the *epigaſtric* region.

EPIGNOMENA, of επιγινομαι, *I ſupervene*, in *Medicine*, are new ſymptoms which occur in the progreſs of a diſeaſe. See EPITHENOMENA.

EPIGLOTTIS, of επι, upon, and γλωττα, or γλωττις, *tongue*, in *Anatomy*, the cover, or lid, of the LARYNX.

The *epiglottis* is a thin, moveable cartilage, made in form of a leaf of ivy, or a little tongue, and therefore likewiſe called lingula; ſerving to cover the cleft, or rima, of the larynx, called *glottis*.

Galen takes the *epiglottis* to be the principal organ, or inſtrument of voice; ſerving to vary, modulate, and render it harmonious.

Its baſe, which is pretty broad, is in the upper part of the cartilago ſcutiformis, and its point, or tip, turned towards the palate. It is only ſhut by the weight of the piece in ſwallowing; though not ſo exactly, but that a crum, or a drop, ſometimes eſcapes through the trachea.

EPIGLOUTIS, a word, uſed by ſome of the old writers in *Medicine*, to expreſs the upper part of the buttock.

EPIGONATIS, a name given, by ſome anatomiſts, to the PATELLA.

EPIGONIUM, ἐπιγονιον, a muſical inſtrument among the ancients, with forty ſtrings, ſo called from its inventor Epigonus, a native of Ambracia, a city of Epirus. Mem. Acad. Inſcript. vol. v. p. 167.

EPIGRAM, in *Poetry*, a ſhort poem, or compoſition in verſe, treating only of one thing, and ending with ſome point, or lively ingenious thought.

The word is formed of ἐπιγραφω, *inſcription*, of ἐπιγραφειν, *to inſcribe*, or *write upon*.

Epigrams then, originally, ſignify *inſcriptions*, and they derive their origin from thoſe inſcriptions placed by the ancients on their tombs, ſtatues, temples, triumphal arches, &c. See INSCRIPTION.

Theſe, at firſt, were only ſimple monograms: afterwards, meaſuring their length, they made them in verſe, to be the more eaſily retained: Herodotus, and others, have tranſmitted to us ſeveral of them.

Such little poems retained the name of *epigrams*, even after the deſign of their firſt inſtitution was varied, and people began to uſe them for the relation of little facts and accidents, the characterizing of perſons, &c.

The Greeks confine their *epigrams* to a very narrow compaſs; for though, in their Anthology, we here and there meet with a very long one; yet, ordinarily, they do not exceed 6, or, at moſt, eight verſes. The Latins were not always ſo ſcrupulous, and the moderns much leſs, as to their bounds.

M. le Brun, in the preface to his *Epigrams*, defines an *epigram* a little poem, ſuſceptible of all kinds of ſubjects, and ending with a lively, juſt, and unexpected thought; which are three qualifications eſſential to the *epigram*; particularly the firſt and laſt of them, *viz.* brevity, and the point or cloſe of the *epigram*.

To attain brevity, only one thing is to be aimed at in the poem, and that to be purſued in the concifeſt terms poſſible. Authors are much divided, as to the length the *epigram* is to be confined to: the ordinary limits are from two to twenty verſes: though we have inſtances, both among the ancients and moderns, where they extend to fifty. But ſtill it is allowed, that the ſhorter the better, and more perfect, as it partakes more of the nature and character of this kind of poem. The point or turn is a quality much inſiſted on by the critics, who require the *epigram* conſtantly to cloſe with ſomething poignant and unexpected, to which all the reſt of the compoſition is only preparatory. Others there are, who exclude the point, and require the thought to be equally diffuſed throughout the whole poem, without laying the whole ſtreſs on the cloſe: the former is uſually Martial's practice, and the latter that of Catullus. Which is the moſt beautiful and perfect manner, is diſputed by a third claſs of critics.

The Greek *epigrams* have ſcarce any thing of the point, or briſkneſs of the Latin ones: thoſe collected in the Anthology, have moſt of them a remarkable air of eaſe and ſimplicity, attended with ſomething juſt and witty; ſuch as we find in a ſenſible peaſant, or a child that has wit. They have nothing that bites, but ſomething that tickles. Though they want the ſalt of Martial, yet, to a good taſte, they are not inſipid; except a few of them, which are quite flat and ſpiritleſs. However the general faintneſs and delicacy of the pleaſantry in them, has given occaſion for a *Greek epigram*, or *epigramma à la Grecque*, to denote, among the French, an *epigram* void of ſalt or ſharpneſs.

It is principally the point that characteriſes the *epigram*, and diſtinguiſhes it from the madrigal. See POINT.

In the modern verſification, as obſerved by F. Mourgues, the *epigram* and madrigal are diſtinguiſhed by the number of verſes and the cloſe. 1. By the number of verſes, which in the modern *epigram* does not go beyond eight, nor in the modern madrigal comes ſhort of ſix; and, 2. In that the cloſe, or period, of the *epigram*, has always ſomething more lively and ſtudied than that of the madrigal.

The *epigram* is the loweſt, and leaſt conſiderable, of all the productions of poetry; and it is in general rather an effect of good luck, than of art, to ſucceed therein. The fineſſe, and ſubtilty, of the *epigram*, M. Boileau obſerves, ſhould turn on the words rather than the thought; which ſeems very little to the credit of this kind of compoſition, as it reduces it to the nature of the pun, or equivoque. F. Bouhours confirms the hint, in adding, that the equivoque is what uſually ſtaines the moſt in the *epigram*.

One great beauty of the *epigram* is, to leave ſomething for the reader to gueſs, or ſupply. Nothing pleaſes the mind ſo much, as to find ſomething in itſelf in the objects preſented to it; nor does any thing diſguſt it more than to preſume it from ſhewing and exerciſing a faculty it values itſelf for. Segrais.

The *epigram* admits of great variety of ſubjects: ſome are made to praiſe, and others to ſatirize, which laſt are much the eaſieſt; ill-nature ſerving inſtead of point and wit. Boileau's *epigrams* are all ſatires on one or another. Thoſe of des Reaux are all made in honour of his friends; and thoſe of Mad. Scudery are to many eloges. The *epigram* being only a ſingle thought, it would be ridiculous to expreſs it in a great number of verſes; it muſt have its unity like the drama. The comedy has an action for its ſubject, and the *epigram* a thought.

EPIGRAPHE, ἐπιγραφη, *Inſcription*, an inſcription on a building, to ſignify its uſe, occaſion, the time when, and the perſons by whom it was built.

EPIGRAPHES, ἐπιγραφεις, among the Athenians, officers that rated all thoſe of whom taxes and contribu-

tions

tions were required, according to every man's ability, kept the public accounts, and prosecuted such as were behind-hand with their contributions. Potter Archæol. Græc. lib. i. cap. 14. tom. i. p. 81.

EPILEPSY, formed of ἐπιλαμβάνω, *I surprize*, or *seize hold of one*, in *Medicine*, a convulsion, either of the whole body, or some of its parts; attended with a deprivation of the senses and understanding; and returning from time to time in fits, or paroxysms.

In English it is usually called the *falling sickness*, because people fall down when attacked by it. The Latins call it *comitialis morbus*, because when any body was seized with it in a comitia, or assembly of the Roman people, they presently broke up the assembly, as deeming it an unhappy prognostic.

Some call it the *morbus sacer*, as supposing it sent by way of immediate punishment from God. Others, *morbus cadurcus*; others *Herculeus*, *pontanus*, *luna dirigens*, &c.

The *epilepsy* is generally preceded by uncommon weariness, pain of the head, dullness, giddiness, noise in the ears, dimness of sight, palpitation of the heart, disturbed sleep, difficult breathing, inflation of the bowels with wind, the evacuation of great quantities of thin urine, pale complexion, coldness at the extremities, and a sensation of cold air, ascending in a kind of stream towards the head.

The patient seized with this disorder, falls instantly and suddenly down: or rather throws and precipitates himself violently to the ground. When down, he grinds his teeth, foams at the mouth, makes an unusual noise, and frequently shakes his head; his arms, legs, neck, back, &c. either becoming rigid, or variously distorted; his thumbs are drawn on towards the palm of his hands; and as all the parts are in a violent contraction, there is frequently an involuntary flux of urine, seed, and fecal matter. After some time he returns to himself; only retaining a head-ach, heaviness, weariness of the limbs, &c.

Some more accurately distinguishes the disease into three degrees: the first, or lowest, is much the same with the highest degree of a vertigo.

In the second, there arise various agitations and gesticulations; and the senses, both external, and internal, either remaining, or being transported into a delirium, they dance, sing, laugh, weep, talk idly, shriek, and beat their breasts. Sometimes they remember all after the fit is over, and sometimes nothing at all of what has passed.

In the third degree, which alone is ordinarily called the *epilepsy*, they lose the use both of reason and sense; fall, or fling themselves down, foam, grind their teeth, and bite their lips, with the other circumstances above related. These affected with the second degree, have been often supposed to be *possessed by the devil*. See DEMONIAC.

The paroxysms, according to the diversity of causes, are longer or shorter, and fewer or more frequent. Some have observed that they generally return at stated periods, as on certain days, hours, or months, or on the changes of the moon, especially at the new and full moon; but there is reason to think, from later observations, that this is a vulgar error. See LUNATICS.

Women are usually seized with these paroxysms at the time of the return of the menses; and what is most observable is, that they are frequently occasioned by seemingly slight causes; commotions of the mind, a concussion than ordinary, the use of strong liquors, close application of the mind to any thing, and, finally, the use of venery often bring on these fits. Infancy and youth are the times of life most subject to this disorder, which often goes off at the time of puberty: it more frequently attacks men than women, and is very difficult of cure, especially if the patient is more than twenty years of age, and after forty, a cure is hardly to be expected. When *epileptic* fits continue long, and return frequently, there is little prospect of relief; and it is a very unfavourable symptom, when the patient is seized with the fits in his sleep.

The cause of this disease Boerhaave attributes to too much action of the brain on the motory nerves, and none on the sensitive ones. Some are pleased to account for it from the abundance of sharp humours mixing with the animal spirits, and giving them extraordinary and irregular motions, and directions; whence arises its distinction from a syncope, and apoplexy, which take away all motion as well as sense. See SYNCOPE, and APOPLEXY.

The cause of this terrible disorder appears to be a fracture of that membrane which surrounds the brain and the spinal marrow. The remote causes are very various, and thence also the disease varies in its species and appearance. The most terrible and mortal *epilepsies* have been brought on by external violence, by blows, wounds, fractures, and depressions of the cranium. These are generally preceded by pains of the head, and a torpor of the senses; and in these, after the patient's death, corrupted blood or serum is always found either between the dura and pia mater, or between the dura mater and cranium. Chronical *epilepsies*, returning at stated periods, are also frequently occasioned by certain acute bony protuberances arising internally in the basis of the cranium, and sometimes in the lateral sinus. It is easy to see that this species of *epilepsy* is incurable; yet medicine can do great service in it, by keeping the brain in such a condition, that its pressure on these protuberances may not be enough to produce a violent fit.

Polypous concretions in the jugular veins, and obstructions of the sinuses of the dura mater, are also causes of incurable *epilepsies*. The passions of the mind also, as anger, fear, and the like contribute greatly to bring on *epilepsies*, as they act immediately upon the nervous parts, and either constringe or dilate them preternaturally, which cannot be done very often without inducing a bad habit. Infants are often rendered *epileptic* either from sucking the milk of a nurse in a violent fit of passion, or from the violent commotions of mind the mother was subject to while pregnant. The terror of the sight of one person in an *epileptic* fit, has frequently thrown another into the same disorder; and it has been often known, that a strong propensity to venery, from a natural redundancy of semen, being suppressed by chastity, has brought on this disease. Women have fallen into it from violent love also, and have, in that case, found their cure in marriage. Excessive drinking, intense study, worms, teething, and the infection of the small-pox, &c. may be reckoned among the causes of this disorder.

M. Poupart, from a dissection of an *epileptic* person, wherein, immediately under the dura mater, was found a deal of white, thick, viscid, pituita, glued, and as it were incorporated with the membrane, thinks, that this might be the cause of the disease; the excessive quantity of such thick lympha, loading the brain, and obstructing its necessary motions. The first cause, he judges, might be the spongeousness of the dura mater, which imbibed the serosities of the brain.

He adds, that he knew an *epileptic* person, who, upon the first approach of his disorder, rubbed his forehead with his hand, and bent his head as far backward as he could, resting it against a wall, and by that means secured himself against the convulsion. It is probable, that by this he gave a motion to the lympha, and drove it from the place which before it disturbed.

The *epilepsy* is either *idiopathic*, or *sympathetic*: it is idiopathic, when it arises merely from a disorder of the brain, or spirits; and sympathetic, when it is preceded by some other disease which brings it on.

In the cure of an *epilepsy*, the first intention must be to correct and expel from the body the remote material causes of the disorder; secondly to mitigate the spasms of the dura mater, and nervous parts, by medicines of a sedative and corroborating nature; the former to check and allay the violent motion of the fibres, the other to restore the due tone, and natural elasticity to the parts, the weakness of which, occasioned by a former fit, gives frequent occasion for succeeding ones. Of the first kind are poppy seeds, or flowers, saffron, nutmeg, and the like; and among the chymical medicines, the *spiritus nitri dulcis*, when truly prepared. Of the corroboratives to be given in *epileptic* cases, rosemary, rue, lavender, camomile leaves, and ambergrise, spirit of hartshorn, and the oil of hartshorn, made pure by frequent rectifications, are also greatly beneficial. The decoctions of the woods, as guaiacum, sassafras, and the like, are also good remedies; and several *epilepsies* have been known to be perfectly cured by taking half a pint of a strong decoction of guaiacum twice a day, with a few drops of spirit of vitriol in each dose, and making all the while a weaker decoction serve for the common drink. It is necessary, however, likewise to keep a requisite share of blood, to help forward the cure with frequent bleedings. Cupping on the parts near the head is also of great service, and sometimes opening the jugular vein is necessary, by which alone patients have sometimes been cured.

But though these are the methods of cure, in some cases, yet in others, where the disease has had a different origin, very different means are required. When the disease is hereditary, or proceeds from a wrong formation of the brain, a cure is not be expected. When it is owing to a debility, or too great an irritability of the nervous system, such medicines as tend to strengthen the nerves may be used, as the Peruvian bark and steel, or the *anti-epileptic* electuaries, recommended by Fuller and Mead. The electary may be made by mixing an ounce of powdered bark, and half an ounce of powdered tin, and as much of wild valerian root, with simple syrup.

Hr.

Dr. Mead directs a dram of an electuary, similar to this, to be taken evening and morning, in the *epilepsy*, for the space of three months. The powdered tin is added, because the *epilepsy* often proceeds from worms.

When an *epilepsy* arises from an impure serum, lodged in the vessels and membranes of the head, which too often happens from the sudden drying up of old ulcers, stopping of issues, or the like means; then the intention of cure consists in the discussion, evacuation, and derivation of the serum to other parts. For this purpose cathartics are to be exhibited, and setons, issues and blisters are of singular service. Nature has been known to cure *epilepsies* of this kind, by an eruption of pimples all over the body. And there is recorded in Willis a memorable instance of a girl, subject to frequent returns of *epileptic* fits; who, in one of them, happening to fall with her head into the fire, and so accidentally cauterising it, remained well as long as the ulcers discharged any thing; but when they dried up, the former fits returned.

In *epileptics* arising from violent emotions of the mind, in which acrid, bilious, and acrimonious humours are conveyed into the nervous system, the use of whey, mineral waters, and proper regimen, added to the sweetening powders, usually produce a cure. Acidulated medicines are also highly proper, and spirit of vitriol, or *spiritus nitro-dulcis*, are of very singular efficacy. When an *epilepsy* arises merely from pain, as that of the stone, the tooth-ach, when violent, or spasms of the stomach or intestines, then clysters of oil are of very great use; and after these, bleeding is usually very proper.

In the *epileptics* of infants, arising from gripes, corrupted milk, or difficult dentition, great benefit is to be had from clysters of milk, with a little Venice soap dissolved in it. A few grains of cinnabar, given internally, often prove also of singular benefit; and musk is known to be a remedy second to none in these cases. When *epileptics* are caused by worms eroding the inner coats of the intestines, after the use of the common *anti-epileptic* remedies, the medicines for worms must be given, and their use continued, till by the symptoms ceasing, there is reason to think these pernicious animals are destroyed.

When an *epilepsy* returns at fixed periods, or at the changes of the moon, the cause is usually in the stomach or duodenum, or in adjacent parts, the biliary ducts and pancreas. In this case, therefore, there should always be a clyster given, and afterwards a vomit, before the expected fit.

In the time of the paroxysms of the *epileptics*, people ought to abstain from the use of substances that are too volatile, spirituous, fragrant, or fetid; for all these fill the head with vapours; nor should such things be exhibited as promote sneezing or vomiting, since they derive the humours to the head, and often recall the paroxysms. The most useful means, in the fit, are to keep the patient in an erect posture, to rub his hands and feet. In all kinds of *epileptics* it is proper to abstain from wine and malt liquors, and to drink only water. Opiates, and too volatile medicines, must be very cautiously given to children, and persons of tender habits; and when *epileptics* return from the slightest causes, it is proper to abstain from a load of medicines, and trust to nature and a proper regimen alone. In this regimen the patient must abstain from all strong liquors, from great heat, or excessive cold, from venery, from seeing any terrible sight, from anxiety of mind, and from business. Young persons are to abstain from fruit; and all violent emotions of the mind are carefully to be avoided.

Many physicians have prescribed the root of the wild valerian, as a remedy which is alone capable of curing this terrible disease. Hoffman extols the use of ambergrise in this disorder. Oper. tom. iii. § 1. cap. 1. § 4. as also of musk, ib. § 9. Ten or twelve grains of it, with the same quantity of sacchinum cinnabar, may be made up into a bolus, and taken every night and morning. He recommends also the spirit of hartshorn, or of ivory, either simple or succinated. The decoctions of the woods guaiacum, sassafras, santals, &c. are also useful, ib. § 4. He advises great caution in the use of opiates, in cases of children, and weak persons. Ib. Cautel. Pract. § 5.

Sir John Colbatch has an express treatise on the MISLETOE of the oak, to prove that it is a specific in this disease.

The *epilepsy* has been sometimes cured by ELECTRICITY.

EPILESMON, from ἐπιλανθάνω, *I cause to forget*, a term used by the old writers in *Medicine*, to express a loss of memory.

EPILOBIUM, in *Botany*. See WILLOW-*herb*.

EPILOGUE, EPILOGUS, in *Oratory*, &c. The peroration, or last part of a discourse, or treatise; containing ordinarily a recapitulation of the principal matters delivered.

The word is Greek, ἐπίλογος, formed of the verb ἐπιλέγω *I say after*; the *epilogue* being the end, or conclusion of a discourse.

EPILOGUE, in *Dramatic Poetry*, is a speech addressed to the audience, when the play is over, by one of the principal persons, or actors in the piece; containing usually some reflections on certain incidents in the play, particularly those of the part of the person who speaks it.

In the modern tragedy, the *epilogue* has usually somewhat of pleasantry in it; intended, perhaps, to compose the passions raised in the course of the representation, and send the audience away in good humour; though how far that design is good and laudable, will bear some dispute: an ingenious author in the Spectator compares it to a merry jig on the organ, after a good sermon, to dismiss an auditory with cheerfulness.

In the modern tragedy, the *epilogue* has usually somewhat of pleasantry in it; intended, perhaps, to compose the passions raised in the course of the representation, and send the audience away in good humour; though how far that design is good and laudable, will bear some dispute: an ingenious author in the Spectator compares it to a merry jig on the organ, after a good sermon, to dismiss an auditory with cheerfulness.

In effect, though the *epilogue*, in this sense, may seem an abuse, yet has it the countenance of antiquity: the Romans had something of the same nature, though under another name. Their exodium was a kind of farce, brought on the stage when the tragedy was over: *ut quicquid lacrymarum ex tristitiâ cupiditate ex tragicis affectibus, hujus spectaculi risus detergeret*, says the scholiast of Juvenal. The *epilogue* is but of modern date, much later than the prologue. Many, indeed, have taken the exodium of the ancient Greek drama for an *epilogue*, because Aristotle defines it to be a part rehearsed after the chorus had sung for the last time; but, in reality, it was of a quite different nature. The exodium was the last of the four parts of the tragedy; containing the unravelling and catastrophe of the plot, and answering to our last, or fifth act.

EPIMEDIUM, in *Botany*. See BARRENWORT.

EPIMELIS, a name given by the old writers in *Medicine*, to a species of medlar, or, as some will have it, to a kind of summer-apple.

EPIMETRON, of ἐπὶ, and μετρον, *measure*, in *Antiquity*, an allowance given the tax-gatherers in the Roman provinces, over and above the just quantity of wine or grain they were obliged to furnish. The *epimetron*, or overmeasure, in different provinces, was different, being always greater in those that were remote, than in the nearer provinces. The different kinds of things wherein it was given, made likewise a difference in the quantity allowed. The reason of allowing an *epimetron*, or overmeasure, was to make good the leakage of the wine, and waste of grain, that would necessarily happen by transporting it to Rome.

The provinces whose taxes were converted into money, and paid in specie, were free from the *epimetron*.

EPIMORIOS, ἐπιμόριος, *superparticular*, of μόριον, *I divide*, an epithet given by Galen to certain differences in the pulse, with respect to their inequality as to the time of their beating. All time, rythm, or modulations of the pulse, according to number, consist, he observes, of equal or unequal proportions. Of equal, when the time of the distention is equal to that of contraction; and of unequal, when the one of these exceeds the other; and this inequality may be from certain or uncertain excesses. The certain excesses may be either in multiple proportion, or as number to number, which is the *epimerion*.

EPIMULIS, of ἐπὶ, *upon*, and μυλὸς, *vobirle bone on the top of the knee*, a name given, by some anatomists, to the patella, or knee-pan.

EPIMYTHION, ἐπιμύθιον, in *Rhetoric*. See FABLE.

EPINEPHELOS, of ἐπὶ and νεφέλη, *cloud*, in the writings of the *Ancient Physicians*, a term used to express the cloudy matter seen floating in the urine, in fevers, &c. See ENEOREMA.

EPINEUX *des lombes*, in *Anatomy*, a name given by Winslow, and some other of the French authors, to certain small muscles of the loins, not mentioned by the old anatomists; but called by Albinus, *interspinales lumborum*.

EPINICION, Ἐπινίκιον, from ἐπὶ, *on*, and νίκη, *victory*, in the Greek and Latin *Poetry*, denotes, 1. A feast, ceremony, or rejoicing, on occasion of a victory obtained. 2. A poem or composition, on the same subject. Scaliger treats expressly of the *epinicion* in his Poetics, lib. i. cap. 44.

EPINYCTIS, of ἐπὶ, and νὺξ, *night*, in the writings of the *Ancient Physicians*, a term used to express a sort of malignant pustule, which commonly breaks out in the night. It is usually of about the bigness of a large pea, and is sometimes white, sometimes black, according to the nature of the humour it contains, and always has a violent

inflammation all round it; when it is opened there is an efflux of ſanies, and a mucous exulceration is found within; it is attended with violent pain, and uſually breaks out in the upper parts of the body. This is the account Celſus gives of the *epinyctis*; but Paulus and Actius underſtand it rather to be a puſtule, which gives no great pain in the day, but is very troubleſome in the night. Both accounts, however, may be right, and it may both firſt appear, and be moſt painful in bed.

EPIPACTIS, in *Botany* a name uſed, by ſome, for the helleborine, or wild, or baſtard black hellebore. Rondeletius alſo uſes the ſame word as the name of the herniaria, or rupture-wort.

EPIPEDOMETRY, of ἐπὶ, *upon*, πούς, *foot*, and μέτρον, *I meaſure*, in *Mathematics*, ſignifies the meaſuring of figures that ſtand on the ſame baſe.

EPIPETRON, in *Botany*, a name given, by Theophraſtus and Ariſtotle, to a plant, ſuppoſed by many to be the ſame with the empetrum of Dioſcorides. But there is great reaſon to doubt whether the *epipetron* of the two older authors be the ſame plant; and whether, if they mean two different plants by this name, either of them agree with the empetrum of Dioſcorides. Theophraſtus ſays, that his *epipetron* never flowers; and Ariſtotle ſays, that his *epipetron* grows on rocky places, and continues to grow after it is taken up, as the orpin and ſome other plants will do.

EPIPHÆNOMENA, of ἐπὶ and φαίνομαι, *ſymptom*, in the writings of the *Ancient Phyſicians*, a term uſed to expreſs ſuch of the ſymptoms, in certain diſeaſes, as did not uſually appear till the time that the diſeaſe was actually formed, called alſo epigimomena.

EPIPHANES, of ἐπὶ and φαίνομαι, an epithet given to Jupiter, becauſe he manifeſted his preſence by lightning and thunder, &c.

EPIPHANIA, a word uſed, by ſome of the ancient phyſicians, to expreſs the external habit of the body.

EPIPHANY, in *Eccleſiaſtical Antiquity*, the feaſt of kings; a double feſtival, of the firſt rank, ſolemnized on the ſixth of January, commonly called *twelfth day*, in honour of the appearance of Jeſus Chriſt to the three kings, or magi, who came to adore, and bring him preſents.

The *feaſt of Epiphany*, now held in honour of the adoration of the magi, had its firſt inſtitution among the Greeks, from a different object, viz. our Saviour's birth; and was called *theophany*, and *epiphany*, that is, appearance, and manifeſtation, of God.

Pope Julius, who reigned from the year 337, to 352, was the firſt who taught the church to diſtinguiſh the feaſts of the nativity, and *epiphany*. Papebroch. Paral. ad Conat. p. 23. Act. SS. Maii, tom. vii.

The word in the original Greek, ἐπιφάνια, ſignifies *appearance*, or *apparition*; and was applied, as ſome critics will have it, to this feaſt, on account of the ſtar which appeared to the Magi. St. Jerom, and St. Chryſoſtom, take the *Epiphany* for the day of our Saviour's baptiſm, when he was declared to men by the voice, *Hic eſt Filius meus dilectus, in quo mihi complacui: This is my beloved Son, in whom I am well pleaſed.* And accordingly it is ſtill obſerved by the Coptites and Ethiopians in that view. See Ludolph. Hiſt. Æthiop. lib. xxi. cap. 2. Others contend, that the feaſt of Chriſtmas, or the nativity of our Saviour, was held in diverſe churches on this day; which had the denomination *Epiphany*, or *appearance*, becauſe of our Saviour's firſt appearance on earth, as at that time. And it muſt be allowed, that the word is uſed among the ancient Greek fathers, not for the appearance of the ſtar to the magi, but for that of our Saviour to the world. In which ſenſe, St Paul uſes the word ἐπιφάνεια, *epiphania*, in his ſecond epiſtle to Timothy, chap. i. ver. 10. Ammianus Marcellinus makes mention of this feaſt, lib. xxi. cap. 2. and obſerves that it was held in January. Upon which paſſage, Valeſius, in his notes, endeavours to ſhew, that the hiſtorian meant by *Epiphany* the feaſt of the nativity.

The heathen writers uſed the word *epiphania* in the like ſenſe, viz. to expreſs the appearance of their gods on earth. And the Chriſtians, after their example, applied it, in the general, to expreſs any appearance, or manifeſtation of the Deity.

EPIPHONEMA, Ἐπίφωνημα. *Acclamation*, in *Rhetoric*, a ſententious ſort of EXCLAMATION, which is frequently added after a narrative, or rehearſal of any thing remarkable; containing uſually a lively, cloſe reflection on the ſubject there ſpoken of, and intended to give it greater force, and render it more affecting to the hearers.

Such is that of St. Paul, when after diſcourſing of the rejection of the Jews, and the vocation of the Gentiles, he cries out,

O the depth of the wiſdom and knowledge of God!

Such alſo is that of Lucretius, after relating the ſtory of Agamemnon's ſacrificing his daughter Iphigenia:

Tantum religio potuit ſuadere malorum!

The *epiphonema* is uſually expreſſive of the milder and more gentle paſſions, and is not ſo vehement and impetuous as EXCLAMATION.

EPIPHEOS, in *Botany*, the name given by the ancients to the DODDER, or cuſcuta, which grew upon the ſhrub they called phæos. This was the ſtæbe of the modern Greeks, deſcribed by Honorius Bellus. It was a cuſtom, among the old writers, to name the cuſcuta, or dodder, from the plant it was found growing upon, as they ſuppoſed that it in ſome degree partook of the virtues of that plant. Thus that which grew upon thyme was called epithymum, and that upon the nettle, epiurtica, and that upon flax, epilinum; ſo of many others.

The ſhrub pheos was alſo called ſtæbe by Dioſcorides and Theophraſtus; and hence this dodder was ſometimes called EPISTEBE.

EPIPHLEBOS, of ἐπὶ and φλὲψ, a *vein*, in the writings of the *Old Phyſicians*, a term uſed to denote ſuch perſons as were lean, and of a hot temperament, and whoſe veins, for that reaſon, appeared uſually very turgid and prominent in the hands, &c.

EPIPHORA, Ἐπιφορὰ, in *Medicine*, a diſeaſe of the eyes; conſiſting in a preternatural defluxion of rheum, or the matter of tears, occaſioned by the partial or total obſtruction of the puncta lachrymalia, or the ſuccus lachrymalis, or the *ductus ad naſum*, and accompanied, frequently, with heat, redneſs, and twitching.

The word is Greek, formed of ἐπιφορὰ, *inferri, to draw* or *bring into*, becauſe of the pain it occaſions.

Pitcairn calls it a *catarrh of the glands of the eye*. See CATARRH.

The internal cauſes of the *epiphora*, of rheum in the eyes, are, a relaxation of the glands of the eyes, and a too great acrimony, or ſharpneſs, of the ſerous humour ſeparated thereby; which, fretting and vellicating the eye, draws an unuſual quantity of blood and lympha thereto; by which, at length, the cheek becomes excoriated, &c. Children are moſt liable to it, from the frequent uſe and ſtraining of the glands of the eye in crying.

The external cauſes of the *epiphora*, are ſharp duſts, ſteams, &c. entering the eye, and irritating the ſame; alſo a too cold and ſharp air has frequently the like effect. An inveterate *epiphora* often degenerates into a FISTULA *lachrymalis*.

The cure of the *epiphora* is, 1. By cauſing a revulſion, or deriſation of the peccant humour, to ſome other parts, as by veneſection, cupping, bliſtering, or cathartics. 2. By correcting its acrimony by proper remedies. And, 3. By applying aſtringents externally. Lapis calaminaris is much commended.

The term *epiphora* is uſed more generally to denote any impetuous influx of the humours, or an inflammation of the blood to any part of the body; and in this ſenſe it may be applied to any inflammatory tumor.

EPIPHYLLOSPERMOUS *plants*, of ἐπὶ, φύλλον, *leaf*, and σπέρμα, *ſeed*, are the ſame with the capillaries, herbs which bear their ſeed on the back part of their leaves. See CAPILLARY.

EPIPHYSIS, Ἐπίφυσις, in *Anatomy*, a leſſer bone, or bony ſubſtance, adhering, or growing to another, by the intervention of a cartilage.

The word is formed of the Greek ἐπὶ, *on*, and φύω, *to grow, adhere*. The Latins call it *appendix, additamentum, adnaſcentia*, &c.

The ſubſtance of the *epiphyſis* is rare and lax; in young children it is merely cartilaginous; but hardens as they grow in age, and at length, becomes quite bony.

It is commonly laid down, that there is no regular articulation between the *epiphyſis* and the bone; though it is certain, that there is a reciprocal admiſſion of the heads or extremities of each, into the cavities of the other. See ARTICULATION.

There are ſome bones that have no *epiphyſes* at all, as the lower jaw; others have no leſs than five, as the vertebræ. The deſign of adding *epiphyſes* to bones, was, to ſupply their defects, and render them longer and bigger at the extremes; and thus to render the articulation more firm, and to give greater force to the action of the muſcles.

EPIPHYSES *vermiformes*, are two eminences of the cerebellum, ſhaped like worms, which keep open the paſſage from the third to the fourth ventricle.

In dilating the third ventricle of the brain, we perceive four eminences, two upper and bigger, called *orbicular protuberances*; and two lower and leſs, called *epiphyſes* of the orbicular protuberances. Diouis.

PIPLASMA, the ſame with *cataplaſma*. See CATAPLASM.

EPIPLOCE, Ἐπίπλοκη, in *Rhetoric*, the ſame with CLIMAX.

EPIPLOCELE, Ἐπιπλοκήλη, in *Surgery*, a kind of hernia, or tumor, occaſioned by the deſcent of the epiploon, or caul,

caul, into the scrotum. See HERNIA, and ENTERO-EPIPLOCELE.

EPIPLOIC, or EPIPLOID, a term applied to the arteries and veins, distributed through the substance of the *epiploon*, or caul. See *Joh. Aust (Angeiol.) fig.* 1. *n.* 37. See EPIPLOON, and GASTREPIPLOICA.

EPIPLOIS *dextra*, is a branch of the coeliac artery, which runs through the right side of the inner, or hinder leaf of the caul.

EPIPLOIS *sinistra*, is a branch of the coeliac artery, springing out of the lower end of the splenica, and running to the hinder leaf of the caul.

EPIPLOIS *sinistra*, is a branch of the coeliac artery, which is bestowed on the lower and left side of the caul.

EPIPLOMPHALUS, or EPIPLOOMPHALON, compounded of ἐπίπλοον, *caul*, and ὀμφαλὸς, *navel*, in *Surgery*, a species of exomphalus, or navel-rupture; being a tumor or swelling of the part, occasioned by the epiploon's falling into it. See EXOMPHALUS, and ENTERO-EPIPLOMPHALUS.

EPIPLOON, in *Anatomy*, a fatty membrane, spread over the intestines, and entering even into the several sinuosities thereof; called also the OMENTUM, and popularly the *caul*.

The word is formed of the Greek ἐπίπλοον, *to swim upon*, because it seems to float on the intestines.

EPIPLOSARCOMPHALUS, compounded of ἐπίπλοον, *epiploon*, σαρξ, *flesh*, and ὀμφαλὸς, *umbilicus*, *navel*, in *Surgery*, a sort of tumor, of the exomphalous kind. It is formed of the epiploon, and the flesh. See EXOMPHALUS.

EPIPOROMA, from ἐπὶ and πόρος, *callus*, a word used by Hippocrates, and the other old writers, for a callous concretion happening at, and mulcting the joints.

EPISARCIDIUM, from ἐπὶ and σὰρξ, *flesh*, a name given by many of the old authors, to an ANASARCA.

EPISCAPHIA, from ἐπὶ and σκάφη, *boat*, feasts celebrated by the Rhodians.

EPISCENIA, from ἐπὶ and σκηνὴ, *tent*, feasts celebrated by the Lacedæmonians.

EPISCENIUM, Ἐπισκήνιον, in *Antiquity*, a place upon the top of the theatre, where all the machines for moving the scenes were kept. Potter, Archæol. Græc. lib. i. cap. 8. p. 42.

EPISCEPSIS, Ἐπισκέψις, in *Antiquity*, an action brought to prove the *diamartyria*, or protestation, that the person deceased had left an heir, to be false and groundless. Potter, Archæol. Græc. lib. i. cap. 24. tom. i. p. 128.

EPISCIRA, Ἐπισκίρα, in *Antiquity*, a festival celebrated at Scira in Attica, in honour of Ceres and Proserpine. Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 395.

EPISCHION, from ἐπὶ and ἰσχίον, *ischium*, a name given, by the old Greek writers, to the pubes.

EPISCIROSIS, Ἐπισκίρωσις, the same with *episcira*.

EPISCOPACY, the quality of episcopal government, or that form of church discipline, wherein diocesan bishops are established, distinct from, and superior to, priests or presbyters. See BISHOP, EPISCOPAL, EPISCOPALIANS, and HIERARCHY.

Episcopacy, and *presbytery*, have been alternately established and abolished in Scotland.

EPISCOPACIDE, from ἐπίσκοπος, *bishop*, and *cædo*, *I kill*, the crime of murdering a bishop by one of his own clergy. By the ancient laws of England, the same obedience is due from a clergyman to his bishop as from a servant to his master; and therefore the offences of murdering either, are made equal, that is, they are both *petty* TREASON.

EPISCOPAL, something that belongs to a bishop.

The word is formed of the Greek ἐπίσκοπος, *overseer*, derived from ἐπισκοπέω, *inspicio*, *I inspect*, or *overlook*.

Episcopal government, is the government of a diocese, wherein one single person, legally consecrated, presides over the clergy of a whole district, in quality of head, or superintendent thereof; conferring order, and exercising a sort of jurisdiction.

The presbyterians reject the *episcopal* establishment, and condemn the *episcopal* orders as a human institution, the mere result of pride and ambition.

Among the *episcopal* functions, the principal part is that of holding frequent visitations of the diocese.

EPISCOPALES *venulæ*, called also, by some, *venulæ mitrales*, two valves in the pulmonary vein, which prevent the reflux of the blood to the heart.

EPISCOPALIA, is sometimes used in the same sense with PONTIFICALIA.

EPISCOPALIA, is also used to denote synodals, or customary payments, due to the bishops from the clergy of their diocese.

These customary payments have been otherwise called *cenæ episcopales*; and were remitted, by special privilege, to free churches and chapels of the king's foundation, which were exempt from episcopal jurisdiction.

EPISCOPALIANS, or EPISCOPISTS, a name given to those who adhere to the church of England, and particularly to the ecclesiastical hierarchy, such as it was in the Romish church before the Reformation; who affect the discipline of bishops, priests, canons, the office, or liturgy, &c. and retain the greatest part of the canon law, with the decretals of the popes, more closely than the catholics themselves of several countries; though, as to matters of doctrine, or faith, they agree in most points with the Calvinists, or Reformed.

In Scotland, the principal dissenters are the *Episcopalians*; lay *Episcopalians* enjoy all the same civil privileges with those of the established church. They are under no restrictions; tied to no tests, but are employed in civil places of trust, upon taking the oaths to the government. But the *episcopal* ministers are liable to several penal laws; many of them being nonjurors.

EPISCOPI *multo*. See MULTA.

EPISCOPISSA, a word used by writers of the middle ages, to denote a bishop's wife.

EPISCOPUS *puerorum*, *bishop of the boys*, a ludicrous kind of office, formerly exercised in churches, in that called the *feast of fools*, or the feast of the kalends.

The custom was for some youth in the feast of Epiphany to plait his hair, that he might seem to have the tonsure, and to put on episcopal garments, and then to exercise a shew of jurisdiction, and do several ludicrous actions; for which reason he was called the *bishop of the boys*. This custom obtained among us, long after several constitutions were made to abolish it. See INNOCENTS-*Day*. See diverse curious particulars concerning this *episcopus puerorum*, in John Gregory's Posthumous Works; and in the Antiquities of the Cathedral Church of Salisbury, p. 71.

EPISPEMASIA, from ἐπισπάομαι, *I signify*, in *Medicine*, is the very time that a disease first seizes a person, and is properly called *ἀρχὴ πλασιώδης*. Blancard.

EPISODE, Ἐπεισόδιον, from ἐπὶ, *upon*, and εἴσοδος, *entry*, is commonly conceived to be a separate incident, story, or action, which an historian, or poet, inserts, and connects with his principal action; to furnish out the work with a greater diversity of events; though, in strictness, all the particular incidents, whereof the action or narration is composed, are called *episodes*.

EPISODE, in *Dramatic Poetry*, was the second part of the ancient tragedy.

The origin and use of *episodes* is described by M. Heidelin, and F. Bossu. Tragedy, in its original, being only a hymn, sung in honour of Bacchus, by several persons, who made a kind of chorus, or concert of music, with dancing, and the like; to diversify the representation a little, and divert the audience, they determined at length to divide the singing of the chorus into several parts, and to have something rehearsed in the intervals.

At first, a single person, or actor, was introduced, then two, then more; and what the actors thus rehearsed, or entertained the audience with, being something foreign, or additional to, or beside, the song of the chorus, and no necessary part thereof, was called ἐπεισόδιον, *episode*.

And hence tragedy came to consist of four parts, the *prologue*, *episode*, *exode*, and *chorus*. The *prologue* was all that preceded the first entrance of the chorus. The *episode*, all that was interposed between the singings of the chorus. The *exode*, all that was rehearsed after the chorus had done singing. And the *chorus*, was the grex, or company, that sung the hymn.

And as this recitation of the actors was in several parts, and inserted in several places, it might either be considered together as a single *episode*, consisting of several parts; or each part might be called a distinct *episode*.

The several *episodes* in the same tragedy might either be taken from so many different subjects, or from the same subject divided into a proper number of recitations, or incidents.

To consider only the first occasion, and institution, of these foreign, or additional pieces, it appears no ways necessary, that they should all be taken from one and the same subject; three or four recitations of different actions, no wise related, or connected to each other, would ease the actors, and amuse the people, in the intervals of the chorus, as well as if they were all so many parts of the same action. By degrees, what was at first only an addition to the tragedy, became the principal part thereof. Then the several pieces, or *episodes*, began to be considered as one single body, which was not to have parts, or members of different nature, and independent of each other.

The best poets took the thing in this light, and drew all their *episodes* from the same action; which practice was so fully established in Aristotle's time, that he lays it down as a rule. Those tragedies wherein this unity and connexion were not observed, he calls *episodic pieces*.

EPISODE, in *Epic Poetry*. The term *episode*, by being transplanted from the ſtage to the *epopœia*, did not change its nature. All the difference Ariſtotle makes between the tragic and epic *epiſodes*, is, that the latter are more ample than the former.

Ariſtotle uſes the word in three different ſenſes: the firſt taken from the enumeration already made of the parts of the tragedy, viz. *prologue*, *chorus*, *epiſode*, and *exode*. Whence it follows, that in tragedy, every thing is *epiſode* that is none of the other parts; ſo that as, among us, there are tragedies without either *prologue*, *chorus*, or *epilogue*, the tragic *epiſode* includes the whole tragedy; conſequently the epic *epiſode* muſt be the whole poem, in like manner; all there is to retrench from it being the propoſition, and invocation, which ſtand in lieu of the prologue. In this ſenſe, the epopœia, and tragedy, have each only one *epiſode*; and if the parts, or incidents, be ill connected together, the poem will be *epiſodic*, and defective.

But farther, as all that was ſung in the tragedy was called the *chorus*, in the ſingular number, yet this ſingularity did by no means prevent every part or diviſion of the ſame from being called a *chorus*, without making ſeveral *choruſes*; ſo it was with the *epiſode*; each incident, and part of the fable and action, is not only a part of the *epiſode*, but is an *epiſode* itſelf.

The term *epiſode*, therefore, in this ſenſe, ſignifies every part of the action expreſſed in the plan, or firſt draught, of the fable; as the abſence and wanderings of Ulyſſes, the diſorders in his family, and his preſence, which retrieved and ſet all to rights again.

Ariſtotle furniſhes us with a third kind of *epiſode*; in ſhewing that what is contained and expreſſed in the firſt plan of the fable is proper, and that all the reſt is *epiſode*.

By *proper* he means what is abſolutely neceſſary; and by *epiſode* what in one ſenſe is neceſſary, and in another not, ſo that the poet is at liberty to uſe, or let it alone.

Thus, Homer, having made the firſt draught of the fable of his Odyſſey, was not at liberty either to make Ulyſſes abſent from his country, or not. His abſence was eſſential; and therefore Ariſtotle ranks it among the things he calls *proper*. But he does not beſtow that appellation on the adventures of Antiphates, Circe, the Sirens, Scylla, Charybdis, &c. The poet was at liberty to have left theſe alone, and to have choſen others in their room; ſo that they are *epiſodes*, diſtinct from the firſt action, to which they are not immediately neceſſary.

This third ſenſe of the word *epiſode* comes to the ſecond: all the difference between them is, that what we call *epiſode*, in the ſecond ſenſe, is the ground, or plan, of the *epiſode* in the third; and that the third adds to the ſecond certain circumſtances which are only probable, and not neceſſary, as the places, princes, and people, among whom Ulyſſes was caſt by Neptune.

It muſt be added, that in an *epiſode* in the third ſenſe, the incident, or *epiſode* in the firſt ſenſe, whereon it is grounded, is to be extended and amplified; otherwiſe, an eſſential part of the action and fable does not become an *epiſode*.

Laſtly, it is in this third ſenſe that we are to underſtand that precept of Ariſtotle, not to make the *epiſodes*, till after the names of the perſons have been choſen. Homer would not have ſpoken of the fleets and ſhips as he has done, if, in lieu of the names of Achilles, Agamemnon, and Iliad, he had choſen thoſe of Adraſtus, Capaneus, and Thebaid.

Upon the whole, the term *epiſode*, in the epic poem, as uſed by the father of the critics, Ariſtotle, does not ſignify any foreign, or accidental adventure; but the whole narration of the poet, or a neceſſary and eſſential part of the action and ſubject, amplified with probable circumſtances.

Thus Ariſtotle enjoins, that the *epiſode* be not added to the action, or fetched from elſewhere; but that it be a part of the action; and never uſes the word *adding*, in ſpeaking of *epiſodes*, though it occurred ſo naturally to his interpreters, that they have generally uſed it in their tranſlations and comments. He does not ſay, that after laying the plan, and chooſing the names, the poet is to add the *epiſodes*; but uſes a derivative of the word *epiſode*, *enneiſodes*, as if in Engliſh we ſhould ſay, *epiſodify* his action.

From what has been ſaid, we may venture to define *epiſodes* to be neceſſary parts of the action, extended and filled up with probable circumſtances. Now an *epiſode* is only a part of an action, and not a whole action; and this part of the action, which is the baſe, or ground of the *epiſode*, muſt not, when *epiſodified*, retain any thing of the ſimplicity which it had when firſt expreſſed in general, in the plan of the fable.

The ſubject of a poem may be lengthened two ways; either by the poet's making uſe of a great many of his *epiſodes*; or by his amplifying, and giving a greater extent to every one. By this latter method, chiefly, it is, that the epic poets lengthen their poems much beyond the dramatic. It muſt be added, that there are certain parts of an action, which, of themſelves, do not naturally preſent or afford more than one *epiſode*; ſuch as the death of Hector, of Turnus, or the like; whereas there are other parts of the fable more copious and fertile, and which oblige the poet to make diverſe *epiſodes* on each, though laid down in the firſt plan with as much ſimplicity as the reſt: ſuch are the battles of the Trojans and Grecians, the abſence of Ulyſſes; the wanderings of Æneas, &c. For Ulyſſes's abſence ſo many years from his own country, required his preſence elſewhere; and the deſign of the fable was to throw him into ſeveral dangers, and different countries. Now each peril, and each new country, furniſhed an *epiſode*, which the poet might uſe, if he pleaſed.

The reſult of the whole is, that *epiſodes* are not actions, but parts of actions; that they are not added to the action and matter of the poem, but make the action and matter themſelves, as the members make the body; that, of courſe, they are not to be fetched from elſewhere, but raiſed from the ground, or baſis, of the action; that they are not united and connected with the action, but with one another; that all the parts of an action are not ſo many *epiſodes*, but only ſuch as are amplified, and extended with particular circumſtances; and, laſtly, that their union with each other is neceſſary in the ground of the *epiſode*, and probable in the circumſtances.

EPISODIC, *in Poetry*. A fable is ſaid to be *epiſodic*, when it is ſwelled with unneceſſary incidents; and its epiſodes are not neceſſarily, nor properly, connected with each other.

Ariſtotle lays it down, that thoſe tragedies are moſt defective, whoſe epiſodes have no connection, or dependence on each other, which he calls *epiſodic*, q. d. *ſuperabundant in epiſodes*; becauſe ſo many little epiſodes can never compoſe one whole one, but neceſſarily remain in a vicious plurality.

If an epiſode be uſed, the names and circumſtances whereof are unneceſſary, and whoſe ground and ſubject make no part of the action, that is of the matter of the poem, ſuch an epiſode renders the fable *epiſodic*. This irregularity is diſcovered, when one may take away a whole epiſode, without ſubſtituting any thing in its room; and yet leave no chaſm, or defect, in the poem. The hiſtory of Hypſipyle, in Statius's Thebaid, affords an inſtance of theſe faulty epiſodes. If the whole ſtory of that illuſtrious nurſe were retrenched, the ſequel of the principal action would be the better for it. Nor would any body imagine he had forgot any thing, or that there was any member of his action wanting. Boſſu, and Ariſt. Poet. cap. 9.

EPISPASTIC, formed of *επι* and *σπαω*, *I draw*, in *Medicine*. See BLISTER.

EPISPHÆRIA, from *επι* and *σφαιρα*, *a ſphere*, in *Anatomy*, are windings and turnings in the outer ſubſtance of the brain, that the ſanguiferous veſſels may paſs more ſecurely.

EPISTAME, in *Botany*, a name given to the cuſcuta, or dodder, found growing on the plant ſtæbe of the ancient Greeks. See EPITHYMUM.

EPISTAPHYLINI, in *Anatomy*, a name given by Winſlow, and other of the French authors, to a muſcle called by Morgagni, the *columnæ muſculi teres*, and the *azygos uvulæ*, which laſt name has been continued to it by moſt authors. Douglas calls it the *palato-ſtaphilinus*, and ſome of the French, the *muſcle de la luette*.

EPISTATES, *Επιστατης*, derived from *επι*, *over*, and *ιστημι*, *I ſtand*, in *Antiquity*, a perſon who has the command and direction of an affair, or of a people.

The term is of conſiderable uſe, in ſpeaking of the government of Athens, where the *epiſtates* was the ſenator in command for that day, or whoſe turn it was to preſide that day. The conſtitution was this: the ten tribes of Athens formed by Cliſthenes, elected every year by lot, each of them, fifty ſenators, which made a ſenate of five hundred. Every tribe had the precedence in its turn, and ſurrendered it again ſucceſſively to another. The fifty ſenators in office were called *prytanes*; the particular place where they aſſembled, *prytaneum*; and the term, or duration of their office, viz. thirty-five days, *prytanea*. During theſe thirty-five days, ten of the fifty *prytanes* preſided weekly, under the name of *proedri*; and of theſe *proedri* there was one to preſide each day of the week, under the title of *epiſtates*.

No perſon was allowed to hold his office more than once in his whole life, leſt he ſhould acquire too much the taſte of dominion: the ſenators of all the other tribes

tribes ſtill voted, according to the order the lot had given them; but the *prytanes* laid the buſineſs before them, and the *epiſtates* took their votes and opinions.

It muſt be added, that of the ten *proedri*, of each week, there were but ſeven that would preſide, each his day, in quality of *epiſtates*; the ten *proedri* elected the ſeven *prytanes*.

EPISTEMONARCH, derived from ἐπιστήμων, *knowledge*, and ἀρχὴ, *command*, a dignitary, in the *Ancient Greek Church*, appointed to watch over the actions of the church, and to inſpect or ſuperintend every thing relating to the faith, in quality of a cenſor. His office anſwered pretty much to that of *magiſter ſacri palatii* at Rome.

EPISTITES, from ἐπιστὰω, *I keep off*, in *Natural Hiſtory*, the name of a ſtone, deſcribed by the writers of the middle ages, as being of a beautiful red, and ſhining very elegantly. It was renowned for its many magical virtues, according to the idle tradition of thoſe times; they ſaid it drove away all noxious animals, and kept off ſtorms from the place where any one was who had it about him.

EPISTLE, a LETTER *miſſive*.

The word is formed of ἐπιστολὴ, *I ſend*.

The term *epiſtle* is now ſcarce uſed, but for letters wrote in verſe, and letters dedicatory.

In ſpeaking of letters written by moderns, or rather in the modern languages, we never uſe the word *epiſtle*. Thus, we ſay, the letters, not *epiſtles*, of the cardinal D'Oſſat, of Voiture, of Balzac, of Howel, of Pope, &c. but thoſe wrote by the ancients, or rather in the ancient languages, we call *epiſtles*: as the *epiſtles*, not letters of Cicero, Pliny, Seneca. The *epiſtles* of St. Paul, St. Peter, St. John, &c. to the Romans, Corinthians, &c.

A TABLE of St. Paul's *Epiſtles*, in the Order of Time, with the places where, and the Times when they were written.

Epiſtles	*Places*		*A. D.*
1 Theſſalonians	Corinth		52
2 Theſſalonians	Corinth		52
Galatians	Corinth, or Epheſus	Near the end of or the beginning of	52 / 53
1 Corinthians	Epheſus	The beginning of	56
1 Timothy	Macedonia		56
Titus	Macedonia, or near it	Before the end of	56
2 Corinthians	Macedonia	About October	57
Romans	Corinth	About February	58
Epheſians	Rome	About April	61
2 Timothy	Rome	About May	61
Philippians	Rome	Before the end of	62
Coloſſians	Rome	Before the end of	62
Philemon	Rome	Before the end of	62
Hebrews	Rome, or Italy	In the Spring of	63

A TABLE of the Seven Catholic *Epiſtles*, ſo called becauſe they were written to Chriſtians in general, and the Revelation, with the Places where, and the Times when they were writ.

Epiſtles.	*Places.*		*A. D.*
The *Epiſtle* of St. James	Judæa	61 or beginning of	62
The 2 *Epiſtles* of St. Peter	Rome		64
St. John's 1ſt *Epiſtle*	Epheſus	About	80
His 2d and 3d *Epiſtles*	Epheſus	Between	80 and 90
The *Epiſtle* of St. Jude	Unknown		64 or 65
The Revelation of St. John	Patmos, or Epheſus		95 or 96

See Lardner's Credibility of the Goſpel Hiſtory, vol. xvi. and vol. xvii.

Learned writers are not abſolutely agreed as to the dates of theſe ſeveral *epiſtles*, nor the places whence they were written. It would lead us too far to examine and produce the various authorities and arguments that have been uſed for ſettling theſe particulars: we ſhall only mention that Dr. Doddridge dates the 1ſt *Epiſtle* to the Corinthians about the year 57; and the 2d *Epiſtle* in 58; thoſe to the Epheſians, Philippians, Coloſſians, and Philemon, in 63; the 1ſt to Timothy, in 58 or 65; the 2d to Timothy, in 66 or 67; the *Epiſtle* to Titus, between St. Paul's firſt and ſecond impriſonment at Rome; the *Epiſtle* of St. James, in 60 or 61; the 1ſt of Peter in 61; the 2d, in 67; that of St. Jude, ſome time after the 2d of Peter, according to Dr. Mills, in the year 90. As to the general deſign of theſe ſeveral *epiſtles*, it is obſerved by Dr. Doddridge, who is deſervedly eſteemed an excellent and uſeful expoſitor, that the *Epiſtle* to the Romans is intended to fix in the minds of the Chriſtians, to whom it is addreſſed, a juſt ſenſe of the excellency of the goſpel, and to engage them to act in a manner agreeable to their profeſſion of it: the *Epiſtles* to the Corinthians are deſigned to reſolve ſome important queries propoſed by them, and to correct the various criminal irregularities and diſorders, of which they were guilty: the principal deſign of the *Epiſtle* to the Galatians was to aſſert and vindicate the apoſtle's authority and doctrine, and to confirm the churches of Galatia in the faith of Chriſt, eſpecially with reſpect to the important point of juſtification; to expoſe the errors that were introduced among them, and to revive thoſe principles of Chriſtianity which he had already taught them. In the *Epiſtle* to the Epheſians, the apoſtle endeavours to eſtabliſh them in the faith; and to this end to give them more exalted views of the divine love and the excellence of Chriſt; to ſhew them that they were now, though Gentiles, made partakers of equal privileges with the Jews; to encourage them, by his own example and concern for their welfare, and to engage them to the practice of duties becoming their Chriſtian character. The *Epiſtle* to the Philippians is deſigned to comfort them under the concern they felt on his account; to check a party-ſpirit that had broke out among them, and to promote union and affection; to guard them againſt the ſeduction of judaizing teachers; to ſupport them under their trials, and to inſpire them with an ambition of excelling in ornamental and diſtinguiſhed attainments. The *Epiſtle* to the Coloſſians is deſigned to excite them to a temper and conduct worthy of their ſacred character, and to ſecure them from the influence of thoſe pagan ſophiſts or Jewiſh bigots, who endeavoured to ſeduce them from the purity of the Chriſtian faith. The two *Epiſtles* to the Theſſalonians are intended to confirm them in their adherence to the Chriſtian faith, and to engage them from the ſufferings they had already endured, and the extraordinary character they had hitherto maintained, to make great advances, and to excel ſtill more in religion and virtue; and alſo to reſtify ſome erroneous apprehenſions they entertained about the coming of Chriſt, and to direct them in the proper exerciſe of Chriſtian diſcipline. The firſt *Epiſtle* of Timothy was partly intended to direct him in managing the affairs of the church, and chooſing proper perſons for the various offices it required; and partly to caution him againſt the influence of judaizing teachers, to urge him to pay a conſtant regard to the intereſts of practical religion, and to animate him to diligence, fidelity, and zeal. The ſecond *Epiſtle* prepares Timothy for the ſufferings that awaited him, forewarns him of the apoſtacy that was beginning to appear in the church, and animates him to the perſevering diſcharge of every part of the miniſterial office. The *Epiſtle* to Titus contains a variety of prudential inſtructions and cautions. The deſign of the *Epiſtle* to the Hebrews was to confirm the Jewiſh Chriſtians in the faith and practice of the goſpel, which they might be in danger of deſerting through the inſinuations or ill-treatment of their perſecutors. St. James, in his *Epiſtle*, aims to correct thoſe errors both in doctrine and practice into which the Jewiſh Chriſtians had fallen, which might otherwiſe have produced fatal conſequences; and then to eſtabliſh the faith and animate the hope of ſincere believers under their preſent and approaching ſufferings. The *Epiſtles* of St. Peter are deſigned to induce the Chriſtian converts in various parts of the world to maintain a conduct inoffenſive and amiable; to ſupport them under their trials, and to encourage their conſtancy, notwithſtanding the artifices of falſe teachers, and the perſecution of their moſt inveterate enemies. The leading deſign of St. John in his firſt *Epiſtle*, is to evince the vanity of faith ſeparate from morality; to inſpire the minds of Chriſtians with mutual charity, and to guard them againſt the ſnares and efforts of Antichriſt, and of all who were endued with his ſpirit. The *Epiſtle* of Jude deſcribes the characters of the falſe teachers, repreſents the divine judgments which ſuch perſons had reaſon to expect, and thus cautions Chriſtians againſt being perverted by them. See Doddridge's Fam. Expoſitor, vol. iv. v. and vi. in the general introduction prefixed to each *Epiſtle*.

EPISTOLARES, among the Romans, under-ſecretaries to the *magiſter ſcrinii epiſtolarum*, or ſecretary who wrote the emperor's letters. They were thirty-four in number. See MAGISTER.

EPISTOLARY, a term uſed in the phraſe *epiſtolary ſtyle*.

As the matter of an epiſtle is the ſame with that of converſation, it ſhould not differ in the manner of expreſſion; and therefore, all pomp and ſtudy of language are not only needleſs but very improper: the moſt plain and eaſy way of conveying our thoughts muſt certainly be beſt, as being moſt natural. Purity in the choice of words, and juſtneſs of conſtruction, joined with perſpicuity, are the chief properties of this ſtyle: to which purpoſe Cicero obſerves, that in writing letters we make uſe of common words and expreſſions. Ad Fam. lib. ix. cap. 21. And Seneca ſays, I would have my letters be like my diſcourſes, when we either ſit or walk together, unſtudied and eaſy. Ep. 75. ad Lucill. However, as the

subjects of epistles are various, they will necessarily acquire some variety in the manner of expression. If the subject be weighty and momentous, the language should be strong and solemn; in things of a lower nature, more free and easy; and upon lighter matters, jocose and pleasant. In exhortations, it ought to be lively and vigorous; in consolations, kind and compassionate; and in advising, grave and serious. In narratives, it should be clear and distinct, in requests, modest; in commendations, friendly, without adulation; in prosperity, cheerful; and mournful, in adversity. In a word, the style ought to be accommodated to the particular nature of the subject about which it is conversant. Besides, the different character of the person, to whom the letter is written, requires a like difference in the modes of expression. Superiors should be addressed with respect; inferiors, with courtesy; and equals, with civility. Old men and young, the grave and facetious, courtiers and philosophers, friends and strangers, require some variety in the mode of address. The Epistles of Cicero, the style of which is plain and simple, and yet pleasant and engaging, furnish a proper model in this respect. Ward's Or. vol. ii. p. 213, &c. See STYLE.

EPISTOLARY, is sometimes also applied to authors who have wrote epistles or letters. The principal *epistolary* authors are Sidonius Apollinaris, Tully, the younger Pliny, Seneca the philosopher, Petrarch, Politian, Busbequius, Erasmus, Lipsius, Muretus, Ascham, Milton, Petau, Launoi, Sarau, Balzac, Voiture, &c.

EPISTOMIA, in *Anatomy*, are the utmost gapings and meetings of vessels.

EPISTOMIUM, Ἐπιστόμιον, from ἐπὶ *upon*, and στόμα *mouth*, in *Hydraulics*, a plug, or instrument, by the application whereof the orifice of a vessel may be opened and shut again at pleasure.

EPISTROPHE, Ἐπιστροφὴ, in *Rhetoric*, a figure wherein that which is supposed of one thing is strongly affirmed of another, and the repetition of the same word occurs at the end of each member or sentence.

Since covetous was lost, friendship was lost, fidelity was lost, liberty was lost, all was lost. Auct. ad Herenn. lib. iv. cap. 13. See also 2 Cor. xii. 22.

EPISTROPHEUS, in *Anatomy*, from ἐπιστρέφω, *converto, I turn about*, the same with *extensor*.

EPISTYLE, Ἐπίστυλον, from ἐπὶ, *upon*, and στῦλος, *columna*, in the *Ancient Architecture*, a term used by the Greeks for what we call *architrave*, viz. a massive stone, or a piece of wood, laid immediately over the capital of a column.

The *epistyle* is the first or lowest member of the ENTABLATURE.

EPITAPH, Ἐπιτάφιον, from ἐπὶ, *upon*, and τάφος, *sepulchre*, a monumental inscription, in honour or memory of a person defunct; or an inscription engraven or cut on a tomb, to mark the time of a person's decease, his name, family, and usually some eloge of his virtues or good qualities.

At Sparta, *epitaphs* were only allowed to people who died in battle. Boxhornius has made a collection of *epitaphs*, not very ample, but exceedingly well chosen. Fa. Labbe has likewise given a collection of the like kind in French, intitled, Trefor des Epitaphes. Camden, Weaver, and Toldervy, have done something in the same way with our English *epitaphs*.

In *epitaphs*, the dead person is sometimes introduced by way of prosopopœia, speaking to the living; of which we have a fine instance, worthy the Augustan age, wherein the dead wife thus bespeaks her surviving husband.

Immatura peri: sed tu, felicior, annis
Vive tuis, comitum optime, vive mei.

The French have a proverb, *Autant vaut comme une epitaphe*; *He lyes like an epitaph*; an allusion to the eloges ordinarily contained therein, which are not always over-just.

EPITAPH, is also applied to certain eloges, either in prose or in verse, composed without any intent to be engraven on tombs.

In the Anthologies, or collections of epigrams, we have abundance of such *epitaphs*, some of them ludicrous and satirical, others grave. For a specimen, we shall here add a very beautiful one, composed by Mr. Cowley, on himself, to be put in a little country-house, whither he retreated from the court and town to spend his last days.

Hic, O viator, sub lare parvulo,
Conditus hic sit conditus, hic jacet
Defunctus humani laboris
Sorte, supervacuique vitæ;
Non indecora pauperie nitens,
Et non inerti nobilis otio,
Vumque dilectis popelli,
Divitiis, animosus hostis.

Possis ut illum dicere mortuum,
Ex terra jam nunc quantula sufficit?
Exempta sit curis, viator,
Terra sit illa levis, precare.
Hinc surgentem, surge heroes volat;
Nam vita gaudet mortua floribus;
Herbisque odoratis corona
Vatis adhuc cinctem calentem.

The following *epitaphs*, besides many others, are worth recording. That of Alexander:

Sufficit huic tumulus, cui non sufficerat orbis.

That of Newton:

Isaacum Newton
Quem immortalem
Testantur tempus, Natura, Cœlum,
Mortalem hoc marmor
Fatetur.

That of Dryden:

Dryden.

Similar to which is that which the Italians have annexed to the Tomb of Tasso:

Ler os da Tasso.

We may also add that of the ingenious and laborious author of this Dictionary, from his tomb in the cloysters of Westminster Abbey, on the north side, written by himself:

Multis perquietus,
Paucis notus;
Qui vitam inter lucem et umbram,
Nec eruditus, nec idiota,
Literis sedulus trunsfugit; sed ut homo
Qui humani nihil a se alienum putat,
Vita simul et laboribus functus,
Hic requiescere voluit
EPHRAIM CHAMBERS,
R. S. S.
Obiit 15 *May*, 1740.

In English thus:

Heard of by many,
Known to few;
Who led a life between fame and obscurity;
Neither abounding nor deficient in learning;
Devoted to study; but as a man
Who thinks himself bound to all offices of humanity;
Having finished his life and labour together,
Here desires to rest.
EPHRAIM CHAMBERS.

EPITASIS, formed of ἐπιτείνω, *intendo, I heighten*, in the *Ancient Poetry*, denoted the second part or division of a dramatic poem, wherein the plot or action proposed and entered upon in the first part or protasis was carried on, heightened, warmed, and worked up, till it arrives at its state or height called the *catastasis*.

This division is laid aside in the modern drama; in lieu whereof our plays are divided into acts. See ACT.

The *epitasis* might ordinarily take up about our second or third act.

EPITASIS, in *Medicine*, denotes the increase or growth and heightening of a disease; or the beginning of a paroxysm, particularly in a fever.

EPITHALAMIUM, Ἐπιθαλάμιον, formed of ἐπὶ and θάλαμος, *bride-chamber*, in *Poetry*, a *nuptial song*, or a composition, usually in verse, on occasion of a marriage between two persons of eminence.

The topics it chiefly insists on are the praises of matrimony, and of the married couple, with the pomp and order of the marriage solemnity: it concludes with prayers to the gods for their prosperity, their happy offspring, &c. This kind of poetry is very ancient: the forty-fourth Psalm, and the book of CANTICLES have been considered as specimens of the *epithalamium*. Stesichorus, who flourished in the forty-second Olympiad, has been usually esteemed the inventor of the *epithalamium*, among the Greeks, though it is known that Hesiod composed the *epithalamium* of Thetis and Peleus, a work now lost; but a fragment of which is preserved by an ancient scholiast. Catullus exceeded all antiquity in his *epithalamium*, and the cavalier Marino all the moderns.

Among the Greeks, the *epithalamium* was sung by young men and maids at the door of the bed-chamber of the married pair in the evening and morning. The former lost were called ἐπιθαλάμια ἀγάμων, and the latter ἐγερτικὰ.

EPITHEM, EPITHEMA, from ἐπὶ, *upon*, and τίθημι, *pono, I put*, in *Pharmacy*, a kind of fomentation or remedy, of a spirituous or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperature thereof. See FOMENTATION.

There are principally three kinds of these external appli-

tations, the liquid, the solid, and the soft or pultice kind.

The liquid *epithems* are sometimes considerably thick; but when they are intended to penetrate deep, they are much better if very thin and fluid; and as the part to which the *epithem* is immediately applied is not what it is always intended to act upon, but something lying deep within, the *epithems* intended for this purpose should consist of the most penetrating ingredients; for which reason aftringents and inspissating remedies can be of no use in this form, since they cannot be absorbed so deep, and indeed prevent their own ingress by bracing up the mouths of the pores. Hot wine alone is sometimes used as an *epithem*; and frequently such medicines as are not to be safely taken inwardly, such as highly rectified spirits, preparations of lead, henbane, mandrake, and other poisonous plants, and the like. But we are carefully to remember in regard to these, that the pores are capable of absorbing them, and ought therefore to know the effect they are capable of producing when thus absorbed in the body. As to the vehicles of liquid *epithems*, they are various, such as linen or woollen cloths, like lotions, toasted bread, crumbs of distrained bread; the dry *epithems* or bags, and sometimes the hot liquor is tied up in a bladder, and that only applied to the part. When a great quantity of the liquor is to be used, flannel drapes do best; but when the heat is to be long retained, and only the finer particles of the liquor admitted, then the bladder preferred and retains beyond all other means.

Epithems are in some cases to be applied hot, and in others cold; when the intention is powerfully to resolve, penetrate, and attract, then those of the hot kind are greatly to be preferred; but heat is injurious to parts conflicted by intenfe cold; and thofe that are cold, or at leaft tepid, are to be ufed. Spirituous and volatile liquors are alfo eafily diffipated by heat, and all fuch ought therefore to be applied either cold, or barely tepid.

The dry *epithems* are medicated powders, ufually fewed up in a cloth, and applied to different parts of the body; for this purpofe the powders muft be coarfe, fince otherwife their particles would fall through the cloth; and fometimes the liquid *epithems* are added to the dry, to reduce the whole to a conftitence, fuch as may be fpread upon cloth.

The ancients ufed chaff of wood to mix with their powders in the *epithems* of the coarfer kind, and cotton in thofe which were finer. Among the dry *epithems* is alfo to be accounted the ufe of a bag of hot fand: this is of fingular fervice where heat is to be retained a long time; and fometimes the liquid *epithems* are added to this, its heat being of power to throw them much farther in than they otherwife would reach. The bags in which any of thefe dry *epithems* are put, muft not be filled hard, but only the matter muft be lightly put in, that they may remain pliant and fpungy. Some make the bags for dry *epithems* of filk, and fome of woollen cloth; but linen, which has been much worn, is greatly preferable on all occafions. The figure of the bag is to be accommodated to the part it is to be applied to, and the intention it is to anfwer. For the head, it is commonly made in the form of a hood; for the forehead, fquare; for the heart, pyramidal; for the ftomach, in form of a fhield; for the liver, in form of a crefcent; and for the fpleen, in fhape of an ox's tongue. When the bags are fmall, it is fufficient to few up the end when the matter is put in; but when they are large, they muft be fewed acrofs in feveral places in the manner of quilting, to keep the matter equally diftributed. When they are thus prepared, they are to be applied either alone, being firft warmed, or moiftened with any proper liquor. Pigeons applied to the feet are alfo a fort of *epithem*.

EPITHEM, *volatile*, *epithema volatile*, a form of medicine prefcribed in the late London Pharmacopœia, and ordered to be made of equal weights of common turpentine and fpirit of fal ammoniac. The turpentine is to be kept continually ftirring in a mortar, and the fpirit gradually dropt in till the whole is reduced to a white maſs.

The fpirit of fal ammoniac ufed in this mixture muft not be that made in the common way, with the addition of quick-lime, but with the alkali fait. Pemberton's Lond. Difp. p. 377.

EPITHESIS, in *Surgery*, a word ufed by fome writers to expreſs the reducing or reſtification of crooked limbs, by means of proper inſtruments.

EPITHET, *Epithĕton*, a noun adjective, expreſſing ſome quality of a ſubſtantive to which it is joined.

The word is formed of ἐπι, *upon*, and τιθημι, *ponĕre*, *to put*, *to place*.

As a fruitful vine, a ſtately pile, an echoing vault, &c. *Epithets* are of great uſe and convenience among poets and orators, who ſupply in *epithets* what they want in other reſpects. Card. Perron even blames Homer on the head of *epithets*, obſerving, that he frequently hooks in *epithets* without any ſenſe or ſignificancy at all, to help out his meaſures; and that he equips every hero with an *epithet*, not according to the exigence of the caſe, but the meaſure of the verſe.

EPITHET, is alſo uſed for a ſurname, or a perſon's ſecond appellation.

Epithets were anciently beſtowed very frankly, either on account of excellencies or defects of the body or mind; king's themſelves were not exempted from them. Hence thoſe *epithets* ſo frequent in hiſtory, as Edward Longſhanks, Richard Cœur de Lion, Edmund Ironſide, Richard Crook-back, John Lackland, &c.

Nor have the French uſed their kings any better, as witneſs their Charles the Simple, Louis the Lazy, Lewis (Ludovicus *nihil faciens*), Pepin the Short, Louis the Stammerer, *le begue*.

EPITHRICADIA, in *Antiquity*, a feſtival in honour of Apollo.

EPITHYME. See DODDER, and EPITHEOS.

EPITOME, an *abridgment*, or a reduction of the principal matters of a larger book into a little compaſs. See ABRIDGMENT.

The word is Greek, ἐπιτομη, formed of ἐπιτεμνω, *reſecare*, *to retrench*, *abridge*, or *cut off*.

The *Epitome* of Baronius's Annals is done by De Sponde (Spondanus). Bernier has given an *Epitome* of the philoſophy of Gaſſendus.

It is a popular objection againſt the *epitomizing* of authors, that it frequently occaſions the loſs of the originals. Thus the loſs of the hiſtorian Trogus Pompeius is attributed to his epitomizer Juſtin, and the loſs of a great part of Livy to Luc. Florus.

EPITRITES, from τρις and τριτος, *third*, in *Proſody*, a foot conſiſting of four ſyllables, three long, and one ſhort.

Grammarians reckon four ſpecies of *epitrites*; the firſt, conſiſting of an iambus and ſpondee, as ſalutantes; the ſecond, of a trochee and ſpondee, as concinat; the third, of a ſpondee and an iambus, as communicas; and the fourth, of a ſpondee and trochee, as locantiſs.

EPITRITES, among the Greek *Muſicians*, denoted a ratio, called alſo the *ſeſquitertial ratio*, the ſame with that of 3 to 4. See FOURTH.

EPITROCHASMUS, in *Rhetoric*, a figure wherein we ſlightly paſs over ſeveral things of great moment, by only mentioning them in general. Such is the ſaying of Cæſar, *Veni*, *vidi*, *vici*.

EPITROPE, in *Rhetoric*. See CONCESSION.

EPITROPUS, a kind of judge, or rather an arbitrator, which the Greek Chriſtians under the dominion of the Turks elect in the ſeveral cities to terminate the differences that ariſe among them, and avoid carrying them before the Turkiſh magiſtrates. See ARBITRATOR.

There are ſeveral *epitropi* in each city. M. Spon, in his Travels, obſerves, that at Athens there are eight taken out of the ſeveral parithes, and called *archiadi*, i. e. old men. But Athens is not the only place where there are *epitropi*; they are in all the iſlands of the Archipelago.

Some Latin authors of the fixth century call *epitropi* thoſe who more anciently were called *curiales*, and ſince *decemviri*.

In times ſtill earlier, the Greeks uſed the term ἐπιτροπος, in the ſame ſenſe as the Latins did *procurator*, viz. for a commiſſioner or intendant.

Thus the commiſſioners of proviſions in the Perſian army are called by Herodotus and Xenophon *epitropi*. In the New Teſtament, ἐπιτροπος, denotes the ſteward of a houſhold, rendered in the Vulgate *procurator*.

EPIZEUXIS, in *Rhetoric*, a figure where the ſame word is repeated in the ſame ſenſe, without any others intervening, and ſuited to expreſs anger, ſurpriſe, ſorrow, and ſeveral other paſſions: thus *age*, *age*; *adeſte*, *adeſte*, and that of Virgil, *mene*, *mene* inſurgite remis, are inſtances of it. See Matthew xxiii. 37.

EPLOYE, in *Heraldry*. An eagle *eployé* is what in Engliſh we more uſually call an *eagle diſplayed*, or *a ſpread eagle*. See DISPLAYED.

EPNEUMATOSIS, from ἐνπνεω, *I breathe*, in *Medicine*, the ſame with EXPIRATION.

EPOBOLIA, in *Antiquity*, a fine laid upon thoſe that could not prove the indictment they had brought againſt their adverſaries.

It was ſo called, becauſe they were obliged to pay the fifth part of the value of the thing they contended for, viz. an obolus out of every drachm. Some of theſe ſums were depoſited in all law-ſuits, a very few excepted, before the trial could proceed. Potter, Archæol. Græc. lib i. cap. 21. tom. i. p. 117.

EPOCHA, in *Chronology*, a term or fixed point of time, whence the ſucceeding years are numbered or accounted.

The word is ἐποχὴ, q. d. *inhibitio*, *repressio*, formed of ἐπέχειν, *to sustain*, *stop*, because the *epocha* defines or limits a certain space of time

Different *epochas* obtain in different nations; and no wonder; for there being no astronomical consideration to render one preferable to another, their constitution is purely arbitrary. That principally regarded among Christians, is the *epocha* of the *Nativity* or incarnation of Jesus Christ; that of the Mahometans, the *Hegira*; that of the Jews, &c. the *Creation of the World*; that of the ancient Greeks, the *Olympiads*; that of the Romans, the *Building of the City*; that of the ancient Persians and Assyrians, the *Epocha* of Nabonassar, &c.

The doctrine and use of *epochas* is of very great extent in chronology.

To reduce the years of one *epocha* to those of another, i. e. to find what year of one corresponds to a given year of another; a period of years has been invented, which, commencing before all the known *epochas*, is, as it were, a common receptacle of them all, called the *Julian period*. To this period all the *epochas* are reduced, i. e. the year of this period whereon each *epocha* commences is determined. All that remains, therefore, is, to add the given year of one *epocha* to the year of the period corresponding with its rise; and from the same to subtract the year of the same period corresponding to the other *epocha*; the remainder is the year of that other *epocha*.

EPOCHA *of Christ*, or *of our Lord*, is the *vulgar epocha* throughout Europe, commencing from the supposed time of our Saviour's nativity, December 25, or rather according to the usual account, from his circumcision, that is, from the first of January.

Now, the year of the Julian period wherein Christ was born and circumcised, is usually computed to be the 4713th: consequently, the first year of the æra of Christ corresponds to the year 4714 of the Julian period.

Hence, 1. If to any given year of Christ you add 4713, the sum will be the year of the Julian period corresponding thereto, E. gr. If to the year 1779 be added 4713 the sum 6492 is that year of the Julian period.

2. On the contrary, subtracting 4713, from any given year of the Julian period, the remainder is the current year of Christ. E. gr. from the year of the Julian period 6492 subtracting 4713, the remainder is the year of Christ 1779.

In effect, the *epocha* of our Lord serves not only for the computation of the years elapsed since the *epocha* commenced, but even of those before it.

Now, to find the year of the Julian period corresponding to a given year before Christ, subtract the given year from 4713, the remainder is the correspondent year required. Thus, e. gr. the year before Christ, 752, is the year 3961 of the Julian period. On the contrary, subtracting the year of the Julian period from 4713, the remainder is the year before Christ.

The author of the vulgar *epocha*, or way of computing from Christ, is an abbot of Rome, one Dionysius Exiguus, by nation a Scythian, who flourished under Justinian about the year 507, or, according to others, 527, though this Dionysius borrowed the hint from Panodorus, an Egyptian monk. Till his time, the generality of Christians computed their years either from the building of Rome, or according to the order of the emperors and consuls, and other ways in use with the people among whom they lived.

This diversity occasioning a great distraction between the churches of the East and West; Dionysius, to compose the same, first proposed a new form of the year, with a new general æra, which in a few years time was generally admitted.

Dionysius began his account from the conception or incarnation, by us popularly called *Lady-day*, or the *Annunciation*; which method obtained in the dominions of Great Britain till the year 1752, before which time the Dionysian and English *epocha* was the same; but in that year the Gregorian calendar having been admitted by act of parliament, they now reckon from the first of January, as they do in the other countries of Europe, except in the court of Rome, where the *epocha* of the incarnation still obtains for the date of their bulls.

It must be added, that this *epocha* of Dionysius is charged with a mistake: the common opinion is, that it places our Saviour's nativity a year too late; or that he was born the winter preceding the time prescribed by Dionysius for his conception.

But the truth is, the fault lies on Beda, who misinterpreted Dionysius, and whose interpretation we follow, as has been shewn by Petavius from Dionysius's own epistles; for Dionysius began his cycle from the year 4712, but his *epocha* from the year 4713, wherein the vulgar æra supposes Christ to have been incarnate.

The year, therefore, which, according to the vulgar *epocha*, is the first year of Christ, according to Dionysius's æra, is the second; so that the year which we call 1779, should, in justice, be 1780, though some chronologers, instead of one year, will have the error two.

Others suppose that the Dionysian æra is four years too late; which supposition is confirmed by considering that our Saviour was born before the death of Herod; and according to the testimony of Josephus, lib. xvii. cap. 18. there was an eclipse of the moon in the time of Herod's last illness; which eclipse appears to have happened in the year of the Julian period 4710, March 13, at Jerusalem. Now, as our Saviour must have been born some months before Herod's death, since in the interval he was carried into Egypt, the latest time in which we can fix the true æra of his birth is about the end of the 4709th year of the Julian period. Ferg. Astr. p. 260.

To this vulgar æra, as a sure fixed point, chronologers have been accustomed to reduce all the other *epochas*, though there is not one of them but what is controverted; so much uncertainty there is in the doctrine of time.

We shall exhibit them as reduced to the Julian period.

EPOCHA *of the Creation, or the Jewish*, according to the computation of the Jews, called also the Jewish *epocha*, is the year of the Julian period 953, answering to the year before Christ 3761, and commencing on the seventh day of October. Hence subtracting 952 years, from any given year of the Julian period, the remainder is the year of the Jewish *epocha* corresponding thereto. Thus, e. gr. the year 1772 being the 6492d year of the Julian period, it is the 5540th year of the Jewish *epocha*, or since the creation of the world.

This *epocha* is still in use among the Jews.

The EPOCHA *of the creation*, used by the Greek historians, is the year before the Julian period, 787, answering to the year before Christ 5500.

Hence, to any given year of the Julian period, adding 787, the sum gives the year of this *epocha*. E. gr. 1779 being the 6492d year of the Julian period, 7279 is that year of this *epocha*, or the year of the world according to this computation.

The author of this *epocha* is Julius Africanus, who collected it from the historians; but when it come to be admitted into civil use, 8 years were added to it, that so every year thereof divided by 15 might exhibit the INDICTION, which the eastern emperors used in their charters and diplomas.

The *epocha of the creation* used by the latter Greeks and Russians is the year 795 before the Julian period, or the year 5508 before Christ, commencing from the first day of September. Though the Russians having lately admitted the Julian calendar, begin their year from the first of January.

Hence, adding 795 to the year of the Julian period, the sum gives the year of this *epocha*. Thus, e. gr. the Julian period of the year 1779 being 6492, that year of this *epocha*, i. e. the years from the creation on this footing are 7287. Again, from that year 7287 subtracting 5508, the remainder is the year of the commonæra 1779. This æra was used by the emperors of the East in their diplomata, &c. and thence also called the *civil æra of the Greeks*. In reality, it is the same with the *epocha* of the Constantinopolitan period; whence some call it the *epocha of the period of Constantinople*.

The Alexandrian EPOCHA *of the creation* is the year 780, before the Julian period, answering to the year before Christ 5493, and commencing on the 29th day of August.

Hence, adding 5493 to the year of Christ 1779, the sum 7272 gives that year of this *epocha*, or years elapsed since the creation, according to this computation.

This *epocha* was first conceited by Panodorus, a monk of Egypt, to facilitate the computation of Easter; whence some call it the *Greek ecclesiastical epocha*.

The Eusebian EPOCHA *of the creation*, is the year of the Julian period 4280, answering to the year before Christ 4228, and commencing in autumn.

Hence, subtracting 4280 from the year 6492 of the Julian period, or adding 4228 to the year of Christ 1779, the result 6006 will be that year of this *epocha*.

This *epocha* is used in Eusebius's Chronicon, and the Roman Martyrology.

The EPOCHA *of the Creation*, according to Mr. Bedford and Mr. Kennedy, is the year of the Julian period 706, answering to the year before Christ 4067; but it must be allowed, that all the *epochs* of the creation are uncertain. See Strauchius's Brev. Chron. by Sault's p. 151, &c.

EPOCHA *of the Olympiads*, is the year of the Julian period 3938, answering to the year 775 before Christ, and the year 3232 from the creation, commencing at the full moon next the summer solstice, and each Olympiad containing four years.

This *epocha* is very famous in ancient history; it was used

used principally by the Greeks, and had its origin from the Olympic games, which were celebrated at the beginning of every fifth year.

EPOCHA *of the building of Rome, or urbis conditæ, U. C.* is the year of the Julian period 1961, according to Varro; or 2960, according to the Fasti Capitolini, answering to the years before Christ 753 or 752, and beginning on the 21st of April. Hence, if the years of this *epocha* be fewer than 753, subtracting them from 754 or 753, you have the year before Christ; and, on the contrary, if they be more than 754, you must subtract 754 to have the year of Christ, and add the year of Christ to 754 to have the year of this *epocha*, or the time since the building of Rome. Thus, e. gr. the year 1779, according to Varro, is the year of Rome 2533.

EPOCHA *of Nabonassar*, is the year of the Julian period 3967, answering to the year before Christ 746, commencing on the 26th day of February.

This æra takes its denomination from its institutor Nabonassar king of Babylon, and is dated by Ptolemy in his astronomical Observations, by Censorinus, and others.

EPOCHA, *Diocletian*, or EPOCHA *of martyrs*, is the year of the Julian period 4692, answering to the year of Christ 284, called the *æra of martyrs*, from the great number of Christians who suffered martyrdom under the reign of that emperor.

The Abassinians, among whom it is still used in all ecclesiastical computations, call it the *year of grace*; though they do not reckon their years in a continued series from this *epocha*. But when the Dionysian period of 534 years is expired, they begin their computation afresh from 1, 2, &c.

EPOCHA *of the Hegira*, or *Mahometan* EPOCHA, is the year of the Julian period 5335, answering to the year of Christ 622. It commences on the 16th of July, the day of Mahomet's flight from Mecca to Medina.

This *epocha* is used by the Turks and Arabs, and even all who profess the Mahometan faith. It was first introduced by Omar, the third emperor of the Turks. The astronomers, Alfraganus, Albategnius, Alphonsus, and Ulugh Beigh, refer Mahomet's flight to the 15th of July; but all the people who use the *epocha* agree to fix it on the 16th. See HEGIRA.

EPOCHA *of the Seleucidæ*, which is used by the Macedonians, is the year of the Julian period 4402, answering to the year before Christ 311. See SELEUCIDÆ.

EPOCHA, *Persian*, or *Yesdegerdic*, is the year of the Julian period 5334, answering to the year of Christ 631, and commencing on the 16th of June.

This *epocha* is taken from the death of Yesdegerdis, the last king of Persia, slain in battle by the Saracens.

EPOCHA, *Galalean*, called also *Royal Epocha*, and *Epocha of the Sultans*, began in the year of the Julian period 5792, on the 14th day of March, at the time of the equinox, and was established for the convenience of finding the vernal equinox, at which time the Persians celebrated their great feast, called *Nouruz*.

EPOCHA, *Julian*, or EPOCHA *of Julian years*, is the year of the Julian period 4667, answering to the year before Christ 46.

This *epocha* had its origin from the year of the reformation of the calendar under Julius Cæsar, called the *year of confusion*.

EPOCHA, *Gregorian*. See GREGORIAN.

EPOCHA, *Spanish*, is the year of the Julian period 4676, answering to the year before Christ 37. See ÆRA.

EPOCHA, *Adam*, or *Adam*, is the year of the Julian period 4684, answering to the year before Christ 29, commencing on the 29th day of August.

Other memorable *epochas* are that of the Deluge, in the year of the creation 1656; that of the birth of Abraham, in 2008 or 2002; the Israelites exodus, or departure out of Egypt, in 2516 or 2511; the building of the temple of Jerusalem, in 2993; and the destruction of the same in the year of Christ 70; the taking of Constantinople by the Turks, in 1453, &c. See *Sacred* CHRONOLOGY.

A TABLE of the most remarkable *Epochas* or *Æras*, and *Events*.

N. B. The years before Christ are those before the reputed year of his birth, and not reckoned back from the first year of Julius, as is generally done in such tables.

	Julian Period.	Year of the World.	Year before Christ.
The creation of the world	706	0	4007
The deluge, or Noah's flood	2362	1656	2351
Assyrian monarchy founded by Nimrod	2537	1831	2176
The birth of Abraham	2714	2008	1999
The destruction of Sodom and Gommorah	2816	2110	1897
Kingdom of Athens founded by Cecrops	3337	2451	1556
Moses receives the Ten Commandments	3422	2536	1491
The entrance of the Israelites into Canaan	3469	2583	1451
The destruction of Troy	3529	2823	1184
The beginning of king David's reign	3650	2944	1063
Solomon's temple founded	3701	2995	1012
The Argonautic expedition	3776	3070	937
Lycurgus formed his excellent laws	3829	3123	884
Arbaces, the first king of the Medes	3838	3132	875
Mandauces, the second	3895	3189	818
Sosarmus, the third	3915	3209	798
The beginning of the Greek Olympiads	3938	3232	775
Artica, the fourth king of the Medes	3945	3239	768
The Catonian *epocha* of the building of Rome	3961	3255	752
The æra of Nabonassar	3967	3261	746
The destruction of Samaria by Salmanasser	3992	3286	721
The first eclipse of the moon on record	3993	3287	720
Cardicra, the fifth king of the Medes	3996	3290	717
Phraortes, the fixth	4058	3352	655
Cyaxares, the seventh	4086	3374	633
The first Babylonish captivity, by Nebuchadnezzar	4107	3401	606
The long wars ended between the Medes and Lydians	4111	3405	602
The second Babylonish captivity, and birth of Cyrus	4212	3408	599
The destruction of Solomon's temple	4125	3419	588
Nebuchadnezzar struck with madness	4144	3438	569
Daniel's vision of the four monarchies	4158	3452	555
Cyrus begins to reign in Babylon	4177	3471	536
Establishment of Roman consuls	4206	3500	507
The battle of Marathon	4223	3517	490
Artaxerxes Longimanus [Ahasuerus] begins to reign	4249	3543	464
The beginning of Daniel's seventy weeks of years	4256	3550	457
The beginning of the Peloponnesian war	4282	3576	431
Beginning of Daniel's weeks, according to Scaliger	4292	3586	421
Alexander's victory at Arbela	4383	3677	330
His death	4390	3684	323
The captivity of 100,000 Jews by Ptolemy	4393	3687	320
The Colossus of Rhodes thrown down by an earthquake	4491	3785	222
Antiochus defeated by Ptolemy Philopater	4496	3790	217
Archimedes murdered at Syracuse	4506	3800	207
Jason butchers the inhabitants of Jerusalem	4543	3837	170
Corinth plundered and burnt by consul Mummius	4567	3861	146
Julius Cæsar invaded Britain	4656	3953	54
He corrected the calendar	4667	3961	46
Was killed in the senate-house	4671	3965	42
Herod made king of Judea	4673	3967	40
Agrippa builds the Pantheon at Rome	4688	3982	25
The true year of Christ's birth	4709	4003	4
The death of Herod	4710	4004	3
The Christian Æra begins here.			Years After Christ.
Dionysian, or vulgar æra of Christ's birth	4713	4007	0
The true year of his crucifixion [Friday April 3d]	4746	4040	33
The destruction of Jerusalem	4823	4077	70
The long wall in Britain, built by Adrian	4833	4127	120
Epocha Diocletian, or of Martyrs	4997	4291	284
The Picts defeated in Britain by Constantius	5019	4313	306
The council of Nice	5038	4332	325
The death of Constantine the Great	5050	4344	337
The Saxons invited into Britain	5138	4432	445
Papal Hierarchy, commenced by Boniface III. who assumed the title of Oecumenical Bishop	5319	4613	606
Arabian Hegira, or flight of Mohammed	5335	4630	622
The death of the false prophet Mohammed	5342	4637	630
The Persian Yesdegerd	5344	4638	631
The art of printing discovered	5413	4427	1440
The Reformation begun by Martin Luther	5830	5544	1517
Reformation of the calendar by Gregory	5895	5609	1582
Oliver Cromwell died	5971	5685	1658
Sir Isaac Newton born, December 25th	5955	5646	1642
Elected fellow of Trinity Coll. Cambr.	5986	5674	1667
Invented the fluxions	5982	5676	1669
Made president of the Royal Society	6416	5780	1703
Knighted by queen Anne	6418	5782	1705
Died March 20th	6446	5734	1727

See Ferguson's *Aſt.* p. 273.

EPOCHE'USIS, from *ἐπέχευσις*, *I draw through a canal*, of *ἐπὶ*, *canal*, a word used by Hippocrates, and others of the old writers in *Medicine*, to express the derivation of the blood, or juices, from one part to another.

EPODE, *Epodus*, *in Lyric Poetry*, the third or laſt part of the ode; the ancient ode, or ſong, being divided into ſtrophe, antiſtrophe, and *epode*.

The *epode* was ſung by the prieſts, ſtanding ſtill before the

altar, after all the turns and returns of the ſtrophe and antiſtrophe.

The *epode* was not confined to any preciſe number, or kind of verſes; as the ſtrophe and antiſtrophe were. But when the ode contained ſeveral *epodes*, ſtrophes, &c. they were all alike.

As the word *epode*, then, properly ſignifies the end of the ſong; and as in odes, what they called the *epode*, finiſhed the ſinging, it became cuſtomary, as M. Dacier ſhews, for any little verſe, which, being put after another, cloſed the period, and finiſhed the ſenſe which had been ſuſpended in the firſt verſe, to be called *epode*, *εποδος*.

And hence it is, that the ſixth book of Horace's Odes is entitled *Liber Epodon*, *Book of Epodes*, becauſe the verſes therein are all alternately long and ſhort; and the ſhort one, generally, though not always, cloſes the ſenſe of the long one. But the ſignification of the word is extended ſtill farther; *epode* being become a general name for all kinds of ſhort verſes, that follow one or more long ones; and in this ſenſe, a pentameter is an *epode*, after an hexameter, which in reſpect thereof is a prode.

EPODOS, from επι and οδος, *ſong*, in *Medicine*, a word uſed to expreſs the curing of diſeaſes by incantation.

EPOICODOMESIS, from εποικοδομεω, *I build upon*, in *Rhetoric*, is ſometimes uſed for what is otherwiſe called CLIMAX.

EPOMIS, Επωμις in *Anatomy*, the upper part of the ſhoulder, reaching up to the neck.

The word is Greek, επωμις, which primarily ſignifies a ſhort cloak or mantle made to cover the ſhoulders.

Some authors apply the word *epomis* to the upper part of the os humeri; but the ancient Greek phyſicians only uſe it for the muſcular, or fleſhy part, placed as above mentioned. See DELTOIDES.

EPOMPHALION, from επι, *upon*, and ομφαλος, *navel*, any medicine which purges, on being applied to the navel.

EPOPOEIA, Επωποια, in *Poetry*, the hiſtory, action, or fable, that makes the ſubject of an epic poem.

The word is derived from the Greek επος, *carmen*, *verſe*, and ποιεω, *facio*, *I make*.

In the common uſe of the word, however, *epopœia* is the ſame with *epos*, or *epic* poem itſelf: in which ſenſe it is defined a diſcourſe invented with art, or a fable agreeably imitated from ſome important action, and related in verſe, in a probable and ſurpriſing manner; with a view to form the manners, &c. See EPIC *Poem*.

EPOPS, in *Ornithology*, a name by which ſome of the ancient writers have called the bird we call the *upupa*, or HOOPOE.

EPOSILINGA, a word uſed, by ſome chemical writers, to expreſs the ſcales which fly off from iron, when hammered at the ſmith's forge.

EPOTIDES, in the *Ancient Ship-Building*, two large thick pieces of wood on each ſide of the prow of a galley, which reſembled two ears, whence they had their name.

The *epotides* were chiefly deſigned to ward off the blows of the roſtra of the enemies veſſels.

EPSOM *ſalt*, Well we now ſhoot with, in the ſhops of chemiſts, under this name, is no other than a ſalt made from the bittern, or remaining brine, after the making of common ſalt; but when the world was firſt made acquainted with a purging ſalt, under this name, it was truly what its name expreſſed, being really made from the purging waters of that place. This ſalt is bitter, and of a ſtrongly purging quality, and, when ſuffered to ſhoot freely, and its cryſtals at a due diſtance, it always formed them into rectangular priſms, with four parallelogrammic planes: by this, and by divers other properties, it appears evidently different from all other ſalts known at that time. It was ſuppoſed to partake of the nature of alum, and the waters of the place were called aluminous waters: but Dr. Grew has evidently proved the error of that opinion; others ſuppoſed this ſalt the ſame thing with the ſalt of lime, or the nitre of old walls, but this was equally erroneous. The beſt method of taking it was found to be diſſolving it in a proper quantity of its own water; by this means the water was made to work both more quickly and more effectually; and it proved of great ſervice in diſorders of the ſtomach, as want of appetite, and the like; and in colics, diabetes, the ſcurvy, and rheumatiſm, and many other chronic diſeaſes. Phil. Tranſ. N° 216. p. 76.

Mr. Boulduc has given much the ſame deſcription of the manner of making *Epſom ſalt*, as Mr. Brown had done in Phil. Tranſ. N° 337. § 10. and N°378. § 11. that it is the ſalt which cryſtallizes, after boiling to a due conſiſtence the bittern, which is the liquor remaining in the ſalt-pans, after the ſea-ſalt is ſeparated. See Mem. Acad Scienc. 1731.

EPSOM *water*. This is a water eaſily imitated by art, i. e. by only diſſolving half an ounce of *Epſom ſalt* in a quart of pure water, made ſomewhat brisk or quick by a few drops of ſpirit of vitriol and oil of tartar, ſo as to let the alkali prevail. Shaw's Lectures, p. 90.

EPTACTIS, in *Natural Hiſtory*, a name given by Linkius, and ſome other authors, to a ſpecies of ſtar-fiſh, of the *aſteriphyte* kind, whoſe rays, or branches, at their firſt going out from the body, are only ſeven in number; but which very ſoon ſpread into more. See STAR-*fiſh*.

EPULÆ. See ENTERTAINMENTS.

EPULARES, in *Antiquity*, an epithet given to thoſe who were admitted to the ſacred *epulæ* or entertainments, it being unlawful for any to be preſent at them who were not pure and chaſte.

EPULETIC *medicines*, the ſame with *cicatrizantia*. See CICATRIZIVE.

EPULIDES, from επι, *upon*, and ουλα, *the gums*, in *Surgery*, certain fleſhy tubercles, or exceſcences of the gums: theſe are of two kinds, ſome being of a mild nature, others painful, malignant, and inclining to be cancerous. Surgeons diſtinguiſh them alſo into the larger and the ſmaller, and the harder and ſofter; they are ſometimes ſupported by a broad, ſometimes by a narrow root. Theſe exceſcences not only deform the mouth, but hurt the ſpeech and maſtication, and are always beſt ſpeedily extirpated.

When they grow to a ſmall root, they are beſt extirpated by ligature, or tying a thread firmly about the root; but when the root is broad, they are beſt eaten off by cauſtics, as the oil of tartar, ſpirit of ſal ammoniac, and the like; and when theſe mild ones prove ineffectual, it is beſt not to have recourſe to ſtronger, but to raiſe the tubercle with the hook or pliers, and carefully extirpate it with the knife, not cutting off the gums, ſo as to uncover the roots of the teeth, which would be probably attended with a caries of the bone. The blood ſhould be permitted to flow from theſe for ſome time; but if the hæmorrhage continue too long, the patient muſt waſh his mouth with hot red wine, with alum diſſolved in it, repeating it till it ceaſes; and afterwards tincture of myrrh, and honey of roſes, ſhould be uſed, till the parts are perfectly well; and if the tubercles ſhould ſprout up again, they ſhould be taken down in time by the ſame methods. Heiſter's Surgery, p. 462. See *alſo* Scheiſhammer, De Epulide. See GUM-*boils*.

EPULIS, *gums*, in *Anatomy*. See GINGIVA and MOUTH.

EPULO, in *Antiquity*, the name of a miniſter of ſacrifice among the Romans.

The pontifices, not being able to attend all the ſacrifices performed at Rome, to ſo many gods, as were adored by that people, appointed three miniſters, whom they called *epulones*, becauſe they conferred on them the care and management of the *epulæ*, feaſts in the ſolemn games and feſtivals.

To them belonged the ordering and ſerving the ſacred banquet, offered on ſuch occaſions to Jupiter, &c. They were a gown bordered with purple, like the pontifices. Their number was at length augmented from three to ſeven, and afterwards by Ceſar to ten.

Their firſt eſtabliſhment was in the year of Rome 558, under the conſulate of L. Furius Purpureo, and M. Claudius Marcellus.

EPULONES. See EPULO.

EPULOTICS, Επουλωτικα, in *Medicine*, drying, aſtringent, remedies, proper to harden, cicatrize, and incarnate wounds, and ulcers.

The word is formed of the Greek επι, *ſuper*, and ουλη, *cicatrix*, *eſchar*; whence the verb ουλοω, *cicatrizo inſero*, *I cicatrize*.

Such are emplaſters of ceruſs, and diapalma; the unguent of pompholyx, &c.

EPULUM, in *Ant quity*, *banquet*, a holy feaſt prepared for the gods.

The ſtatues of the gods were commonly laid upon a bed, and ſerved in the *epula* as if they had been very hungry; to perform which, was the function of the miniſters of ſacrifice, hence called *epulones*.

EQUABLE *motion*, is that whereby the moveable body proceeds with the ſame continued velocity; neither accelerated nor retarded.

EQUABLE *pulſe*. See PULSE.

EQUABLE *ſtyle*. See STYLE.

EQUAL, a term of relation between two or more things of the ſame magnitude, quantity, or quality.

Wolfius defines *equale* to be thoſe things which may be ſubſtituted for each other, without any alteration of their quantity. It is an axiom in geometry, that two things which are *equal* to the ſame third, are alſo *equal* to each other. And again, if, to or from *equals*, you add or ſubtract *equals*, the ſum or remainder will be *equal*.

EQUAL *circles*, in *Geometry*, are thoſe whoſe diameters are *equal*. See CIRCLE.

EQUAL *angles*, are thoſe whoſe containing lines are inclined

alike to each other; or which are measured by fimilar arches of their circles.

EQUAL *arches*. See ARCH.

EQUAL *figures*, are thofe who areas are equal; whether the figures be fimilar, or not.

The fegments of a fphere, or circle, are of an *equal* concavity, or converxity, when they have the fame ratio, or proportion to the diameters of the fpheres, or circles, whereof they are parts.

EQUAL *folids*, are thofe which comprehend, or contain, each as much as the other; or whofe folidities, or capacities, are *equal*. See SOLID.

EQUAL *hyperbolas*, are thofe, all whofe ordinates to their indeterminate axes, are *equal* to each other; taken at *equal* diftances from their vertices.

EQUAL *hours*. See HOUR.

EQUAL *geometrical ratios*, are thofe whofe leaft terms are fimilar, aliquot, or aliquant parts of the greater.

EQUAL *arithmetical ratios*, are thofe wherein the difference of the two leaft terms is equal to the difference of the two greater. See RATIO.

EQUAL, in *Optics*. We fay, that things feen under *equal* angles, are *equal*. *Equal* parts of the fame interval, or magnitude, if unequally diftant from the eye, appear unequal. *Equal* objects, and at *equal* diftances, only the one placed directly, and the other obliquely, feem unequal; and that placed directly, the bigger.

Malters by EQUAL *courfes*. See MASONRY.

EQUALITY, in *Aftronomy*. *Circle of* EQUALITY, or the *equant*. See CIRCLE and EQUANT.

EQUALITY, *ratio*, or *proportion of*, in *Geometry*, is that between two equal numbers, or quantities.

Proportion of EQUALITY *evenly ranged*, or *ex æquo ordinata*, is that wherein two terms in a rank, or feries, are proportional to as many terms in another feries, compared to each other in the fame order, i. e. the firft of one rank to the firft of another; the fecond to the fecond, &c.

Proportion of EQUALITY *evenly difturbed*, called alfo *ex æquo perturbata*, is that wherein more than two terms of a rank, are proportional to as many terms of another compared to each other, in a different and interrupted order; viz. the firft of one rank to the fecond of another; the fecond to the third, &c.

EQUALITY, in *Algebra*, is a comparifon of two quantities, that are equal both really, and reprefentatively, i. e. which are fo both in effect and letters.

A comparifon of two quantities, equal in effect, but unequal in letters, to render them equal, is called an *equation*.

Equality, in *Algebra*, is ufually denoted by two parallel lines, as =; thus, 2+2=4, i. e. 2 plus 2, are equal to 4. This character was firft introduced by Harriot. Des Cartes, and fome after him, in lieu thereof, ufe ∝: thus, 2 + 2 ∝ 4; fo z−y ∝ b+c, fignifies that z minus y, is equal to b plus c.

From an equation we arrive at an *equality*, by changing an unknown letter into another, whereby the two members of the equation, i. e. the two quantities compared together, and connected by the fign of *equality*, are rendered equal.

Thus, in the equation $\frac{bcd}{aa}x=bcd$; fuppofing $x=\frac{bcd}{aa}$, we change x into $\frac{bcd}{aa}$, and by this fubftitution arrive at the *equality* $\frac{bcd}{aa}bcd=bcd$.

In the folution of a numerical problem, which is to be rendered rational, if there be only one power to be equalled to a fquare, or other higher power, it is called *fimple equality*.

When there are two powers to be equalled, each to a fquare, it is called *double equality*, &c.

Diophantus hath given us a method for *double equalities*, and F. de Billy, another for *triple equalities*, in his Diophantus Redivivus.

EQUALITY, *union of*. See UNION.

EQUALITY, in *Law*, the law delights in *equality*: fo that when a charge is laid upon one, and divers ought to bear it, he fhall have relief againft the reft. 2 Rep. 25.

EQUANIMITY, in *Ethics*, denotes an even, uniform temper of mind, amidft all the varieties and revolutions of time and chance. This virtue, together with prudence, forms the character which Horace gives of Ariftippus:

Omni Ariftippum decuit color & ftatus & res.

EQUANT, or ÆQUANT, in *Aftronomy*, a circle, formerly imagined by aftronomers, in the plane of the *deferent*, or eccentric; for regulating and adjufting certain motions of the planets, and reducing them more eafily to a calculus. See APOGEE, CIRCLE, DEFERENT, and ECCENTRIC.

EQUATED *anomaly*. See ANOMALY.

EQUATED *bodies*. On Gunter's SECTOR there are fometimes placed two lines, anfwering to one another, and called the *lines of equated bodies*: they lie between the lines of folids and fuperficies, and are noted with the letters D, I, C, S, O, T, for dodecahedron, icofahedron, cube, fphere, octahedron, and tetrahedron.

The ufe of thefe lines are, 1. When the *diameter* of the fphere is given, to find the fides of the five regular bodies, feverally equal to that fphere. 2. From the *fide* of any of the bodies being given, to find the diameter of the fphere, and the fides of the other bodies, which fhall be equal feverally to the firft body given.

If the fphere be firft given, take its diameter, and with it over in the feftor in the points S, S; if any of the bodies be firft given, apply the fide of it over in the fame points; fo the parallels taken from between the lines of the other bodies, fhall be the fides of thofe bodies refpectively equal to the firft body given.

EQUATION, or ÆQUATION, in *Algebra*, an expreffion of the fame quantity, in two different, that is, diffimilar, but equal terms or denominations.

As, when we fay, 2×3=4+2; that is, twice three is equal to four and two.

Stifelius defines *equation* to be the ratio of equality between two quantities differently denominated; as when we fay 3 fhill. = 36 pence. Or 50 fhill = 2l. 10s. = 600 pence, = 2400 farth. Or, $b=d+e$. Or, $z=\frac{a+b}{5}$, &c.

Hence, the reduction of two heterogeneous, or diffimilar quantities to the fame value, i. e. to an equality, is called the *bringing them to an equation*. See EQUALITY.

The character, or fign of an *equation*, is = or ∝.

The refolving of problems, by means of *equations*, is the bufinefs of algebra.

EQUATION, *terms of an*, are the feveral quantities, or parts, of which an *equation* is compofed, connected together by the figns + and −. Thus, in the *equation* $b+c=d$; the terms are b, c, and d. And the tenor or import of the *equation* is, that fome quantity, reprefented by d, is equal to two others reprefented by b and c.

EQUATION, *root of an*, is the value of the unknown quantity in the *equation*. E. gr. if $z^2+b^2=a^2$, the root will be $\sqrt{a^2+b^2}$. See ROOT *of an equation*.

Equations are divided, with regard to the powers of the unknown quantities, into *fimple*, *quadratic*, *cubic*, &c.

EQUATION, *fimple*, is that wherein the unknown quantity is only of one dimenfion, or in the firft power. As, $z=a+b$.

EQUATION, *quadratic*, is that wherein the unknown quantity is of two dimenfions, or in the fecond power. As, $z^2=a^2+b^2$.

Quadratic equations are of two kinds; *fimple* or *pure*, and *affected*.

Simple, or *pure quadratics*, are thofe where the fquare of the unknown root is equal to the abfolute number given: as in $aa=36$; $xx=144$; $yy=3125$.

The refolution of thefe is eafy; it being apparent that nothing more is required than to extract the fquare root out of the number or known quantity.

Thus the value of x in the firft *equation* is equal to 6; in the fecond $x=12$, and a little more, as being a furd root; and in the third example $y=56$.

Affected quadratics, are thofe which between the higheft power of the unknown number, and the abfolute number given, have fome intermediate power of the unknown number; as, $xx+2ax=100$.

All *equations* of the rank are in one or other of the following forms; viz. $xx+ax=$ R. $xx-ax=$ R. $ax-xx=$ R.

There are feveral methods of extracting the roots of *affected quadratics*; the moft convenient is that of Harriot. Suppofe $x^2+ax=+b^2$; here x being aflumed as a part of the root; a, the known quantity of the fecond term, will be double the other part, and therefore half of a is the other part.—The fquare thereof will be completed, by adding one fourth of a^2; which done, the root of the fquare may be extracted thus:

$x^2+ax=b^2$

add. $\frac{1}{4}aa=\frac{1}{4}aa$

$x^2-ax+\frac{1}{4}a^2=b^2+\frac{1}{4}a^2$

$x-\frac{1}{2}a=\sqrt{b^2+\frac{1}{4}a^2}$

$x=+\frac{1}{2}a+\sqrt{b^2+\frac{1}{4}a^2}$

In lieu of the characters + and −, we here ufe points, to avoid the neceffity of diftinguifhing feveral cafes. See REDUCTION *of equations*.

EQUATION, *cubic*, is that wherein the unknown quantity is of three dimenfions: as, $a^3=z^3-b^3$, &c.

The second terms of a cubic *equation* being taken away, they may be all reduced to this form, $x^3+ax+b=0$. Where

$$x=\sqrt[3]{-\tfrac{1}{2}b+\sqrt{\tfrac{1}{4}bb+\tfrac{1}{27}a^3}}+\sqrt[3]{-\tfrac{1}{2}b-\sqrt{\tfrac{1}{4}bb+\tfrac{1}{27}a^3}}.$$

This rule is commonly ascribed to Cardan, and from him has been called *Cardan's rule*; but it is said by some, that Tartalea was the inventor, and, by others, Scipio Ferreus, to whom, it is said, Cardan himself ascribes the invention. Leguil, Elem. d'Arithmet. & d'Algebr. p. 479. Wolf. Elem. Mathef. tom. i. p. 336. edit. 2. and When in a cubic *equation*, $x^3=ax\pm b=0$, a is negative, Saunderson's Algebra, p. 702. See REDUCTION *of equations*.

the expression $\sqrt[3]{\frac{1}{2}bb+\frac{1}{27}a^3}$, will be transformed into $\sqrt[3]{\frac{1}{2}bb-\frac{1}{27}a^3}$, which becomes impossible, or imaginary, when $\frac{1}{27}a^3$ is greater than $\frac{1}{2}bb$; for $\sqrt{\frac{1}{4}bb-\frac{1}{27}a^3}$ will then be the square root of a negative quantity, which is impossible. And yet, in this case, the root x may be a real quantity; but algebraists have not been able to find a real expression of its value. The case is called the *irreducible*, *irreducible*, or impracticable case. See IRREDUCIBLE.

The irreducible case may be solved by the trisection of an arc, for which the reader may consult Saunderson's Algebra, p. 713. This method requires a table of sines; and if such be not at hand, we have recourse to Dr. Halley's universal method of extracting the roots of *equations*, in the Philosophical Transactions, or in Lowthorp's Abridgment, vol. i. cap. 1. § 20. Vide infra.

There are several other methods of extracting the roots of cubic *equations*, extant in books of Algebra.

Mr. Cotes observes, in his Logometria, p. 29. that the solution of all cubic *equations* depends either upon the trisection of a ratio, or of an angle. See this method explained and demonstrated in Saunderson's Algebra, p. 718.

EQUATION, *biquadratic*, is that wherein the unknown quantity is of four dimensions; as, $x^4=ax^3+b^2$. See BIQUADRATIC. Des Cartes gave a method of reducing biquadratic *equations*, to cubic. This method is explained in most treatises of algebra, since his time; and very clearly by the marquis de l'Hôpital in his Conic Sections, art. 356. See also Maclaurin's Algebra, p. 228, seq. See REDUCTION *of equations*.

Hence a biquadratic *equation* being proposed, it may be solved, by reducing it first to a cubic *equation*; and then finding the roots of this new *equation*, by the trisection of an angle, or of a ratio. These roots, so found, having a given relation to the roots of the proposed biquadratic, will also be given.

EQUATIONS *of higher degrees*. If the unknown quantity in an *equation* is of five dimensions, it is called a *surfolid*, &c. We have no universal rule to express, algebraically, the roots of *equations*, higher than biquadratic; but such *equations* may be solved universally in numbers, by Dr. Halley's method of approximation.

This method proceeds by assuming the root defired, nearly true to one or two places; which may be done by a geometrical conftruction, or by a few trials; and then correcting the aſſumption, by comparing the difference between the true root and the aſſumed, by means of a new *equation*, whoſe root is that difference, and which he ſhews how to form from the *equation* propoſed, by ſubſtitution of the value of the root ſought, partly in known, and partly in unknown terms.

Dr. Brook Taylor found that this method was capable of a greater degree of generality, and that it was applicable, not only to *equations* of the common form, that is, to ſuch as conſiſt of terms, wherein the powers of the root are poſitive and integral, without any radical ſign, but alſo to all expreſſions in general, wherein any thing is propoſed as given, which by any known method might be computed; if, *vice verſa*, the root were conſidered as given. Such are all radical expreſſions of binomials, trinomials, or of any other nominal, which may be computed by the root given, at leaſt, by logarithms, whatever be the index of the power of the nominal; as likewiſe expreſſions of logarithms, of arches by the lines or tangents, or arcs of curves by the abſciſſæ, or any other fluents, or roots of fluxional *equations*. See Phil. Tranſ. N° 352. Jones's Abridg. vol. iv. cap. 1. § 17.

The method of finding the roots of *equations* by approximation, extends to all kinds of *equations*; and though it be not accurately, yet it is practically true; as it gives the value ſought to a very great degree of exactneſs, nay to any aſſignable degree, if any one will take the pains of computation.

The method of Sir Iſaac Newton, and of Mr. Raphſon, is, in effect, the ſame as that mentioned under the head APPROXIMATION. See farther in Newt. Meth. of Flux. and Mr. Colſon's Comment. p. 180. But Dr. Halley's method is more expeditious in practice. See Phil. Tranſ. N° 216. or Lowthorp's Abridg. vol. i. cap. 1. § 20. The principles of theſe methods may alſo be found in Mr. Maclaurin's Algebra, part ii. cap. 9. or in Mr. Simpſon's Algebra, p. 147. ſeq. who gives ſeveral formulæ for approximating to the roots of *equations*. This gentleman has alſo another method for this purpoſe, which we ſhall mention farther on.

Mr. Daniel Bernouilli, in the Acta Petropolitana, tom. iii. p. 92. ſeq. has given a new and ingenious method of approximating to the roots of *equations*, without any previous trials. The method is deduced from the nature of recurring ſeries. The book wherein it is publiſhed being in few people's hands, we ſhall here give a full account of this method.

Let the propoſed *equation* be put into this form:

$$1=ax+bxx+cx^3+dx^4+, \&c.$$

Then form a ſeries, beginning with as many arbitrary terms as the *equation* has dimenſions, but with this condition, that if A, B, C, D, E, &c. denote the terms following each other in direct order, then muſt $Ea-Db+Cc+Bd+Ae+, \&c.$ and let there be two proximate terms, M and N, in this ſeries ſufficiently continued; then will the antecedent M, divided by the conſequent N, be nearly equal to the required root.

For inſtance, let $1=-2x+5xx-4x^3+x^4$. Form a ſeries, beginning with four arbitrary numbers, 1. 1. 1. 1 (as the propoſed *equation* is of four dimenſions) and let a new term always be formed from the double of the laſt preceding taken negatively, more the quintuple of the penultimate, leſs the quadruple of the antepenultimate, more the pentantepenultimate. This ſeries will be 1. 1. 1. 1. 0. 2. −7. 25. −93. 341. −1254, &c. and the approximated root of the *equation* propoſed will be nearly $\frac{341}{-1254}$.

Again, let $1=x+2xx+3x^3+4x^4+5x^5$. Form a ſeries, beginning with five arbitrary terms, 1. 1. 1. 1. 1. 15. 29. 71. 183. 477. 1209. 3171, &c. Here $\frac{71}{183}$, or $\frac{2}{5}$, will be nearly equal to one of the roots of the *equation*.

The root here found is the leaſt of the roots, without attending to the ſigns; that is, the root ſo determined is that which is leaſt diſtant from nothing.

To find the greateſt root of a propoſed *equation*, let it be diſpoſed in the following manner:

$$x^n=m^{n-1}+fm^{n-2}+gm^{n-3}+\ldots+d.$$

Then form a ſeries, beginning with as many arbitrary terms as there are dimenſions in the *equation*, ſo that if A, B, C, D, E, &c. denote ſo many contiguous terms directly following each other in the ſeries, E muſt be every where $=fD+gC+hB+iA$, &c. Laſtly, let there be two proximate terms, M and N, in this ſeries ſufficiently continued, then will the conſequent term N, diviſed by the antecedent M, be nearly equal to the required root.

For inſtance, let us take one of the foregoing *equations*, the root of which was found to be $-\frac{2}{5}$; and let the *equation* be thus diſpoſed;

$$x^4=4x^3-5xx+2x-1.$$

Then form this ſeries,

$$1. 1. 1. 1. 0. -4. -15. -41. -57. -209.$$

And $\frac{209}{57}$ will be nearly equal to the greateſt root of the propoſed *equation*.

In the application of the rule for finding the leaſt root, the author obſerves, that ſome difficulties may ariſe in two caſes. Firſt, when the leaſt root of the *equation* may be taken either affirmatively, or negatively. Secondly, when the leaſt root is imaginary, as if the *equation* had theſe roots, $+\sqrt{-4}$. $-\sqrt{-4}$, and 5; of which the laſt is to be conſidered as greateſt, that is, according to his definition, as fartheſt diſtant from nothing.

In the firſt caſe, the alternate terms only are to be conſidered; and if they tend towards a conſtant ratio, while the contiguous terms deviate, it will argue an equality between the affirmative and negative root. And, in this caſe, a term in the ſeries muſt be diviſed by the alternate term following; and the ſquare root of the quotient will be the root of the *equation*. For inſtance, if we had, $1=-1+4x+4x^3$; then forming a ſeries according to the firſt rule, we ſhall have 1. 1. 0. 8. −4. 36. −20. 128. −84. 596. −340. 2768, &c.

And the tenth term 596, diviſed by the alternate term following, or the twelfth, 2388, gives $\frac{149}{597}$, or $\frac{1}{4}$, nearly equal to the ſquare of the required root, which will therefore be, nearly $+\sqrt{\frac{1}{4}}$. This example ſhews that the rule approximates ſufficiently faſt; for the number found $\frac{149}{597}$ differs from the truth only by $\frac{1}{597}$, the true root being $+\frac{1}{2}$. The inconvenience, here mentioned, might alſo be remedied, by making $x=y+\frac{1}{2}$; and then finding the root of the tranſformed *equation* by the firſt rule.

In

In the fecond cafe, when the leaft root is imaginary or impoffible, it is to be conſidered whether the root will be affirmative or negative; if the former, put $x = y + s$. If the latter, $x = -s$. And then the value of y may always be found by the rule; provided that s be aſſumed greater than x. But though we ſhall never be diſappointed by taking any greater number for s; yet it is to be obſerved, that the leſs $s - x$ is, the more eaſily and quickly will the ſeries tend to the required root. Some circumſpection is therefore requiſite.

For inſtance, let $1 = \frac{x + xx - x^3}{2}$.

If we form a ſeriet without any previous examination, ſuch as $1 . 1 . 1 . \frac{1}{2} . \frac{1}{4} . \frac{3}{8} . \frac{9}{16} . \frac{11}{32} . \frac{17}{64}$, &c. we ſhall never find any root, as the terms of the ſeries do not tend to any conſtant ratio. But ſuppoſing $x = y - 2$ (for it is viſible that the negative root cannot be great) we ſhall have

$$1 = \frac{15y - 7yy + y^3}{8}$$

or to avoid fractions, ſuppoſe, $y = 8z$, that is, $x = 8z - 2$. Then we have

$$1 = 15z - 56zz + 64z^3.$$

From this *equation* the following ſeries ariſes:

$$1 . 1 . 1 . \frac{23}{15} . \frac{353}{225} . \frac{4071}{3375} . \frac{42769}{50625} . \frac{430151}{759375}, \text{ &c.}$$

Hence $z = \frac{42769}{430151}$; and $x = \frac{-530150}{430151}$.

For a ſecond example, take this *equation*.

$$1 = \frac{-x - xx + x^3}{2}$$

; from whence this ſeries ariſes,

$$1 . 1 . 1 . \frac{1}{2} . \frac{3}{4} . \frac{5}{8} . \frac{11}{16} . \frac{5}{32} . \frac{37}{64} . \frac{91}{128}, \text{ &c.}$$

Which gives no root; but taking $x = y + 3$ (as it appears that x muſt be affirmative) this *equation* will ariſe, $1 = \frac{-20y - 8yy + y^3}{13}$, or rather taking $y = 13z$, that is, $x = 13z + 3$, we ſhall have $1 = -208z - 104zz + 169z^3$.

This laſt *equation* gives the following ſeries:

$$0 . 0 . 1 . -20 . 296 . -4069 . 52776 . -688608.$$

Whence $z = -\frac{42776}{688608}$; and $x = \frac{1379736}{688608} = 2{,}0036$ nearly; x being exactly $= 2$.

As to the caſe before mentioned, of the equality of two roots, it is alſo to be obſerved, that a like rule may be applied, where more than two roots are equal, provided they be real. But in caſe ſome of theſe equal roots ſhould be impoſſible, and the reſt real; as if $x^4 - 1 = 0$, where $x = 1$, $x = -1$, $x = \sqrt{1}$, and $x = -\sqrt{-1}$, all which roots, by our author's definition, are to be conſidered as equal, or equally diſtant from nothing: we may obviate this inconvenience, by ſuppoſing $x = y + s$, which is therefore an univerſal remedy.

This will lead us to a method of extracting the roots of powers. For inſtance, if we wanted the cube root of 2.

Then $x^3 = 2$ or $1 = \frac{2}{x^3}$.

The ſeries, formed according to this *equation*,

$$1 . 1 . 1 . \frac{1}{2} . \frac{1}{2} . \frac{1}{2} . \frac{1}{4} . \frac{1}{4} . \frac{1}{4} . \frac{1}{8} . \frac{1}{8} . \frac{1}{8}, \text{ &c.}$$

only ſhews, that $x^3 = 2$. But taking $x = y + 1$, the propoſed *equation* will be tranſformed into the following, $1 = 3y + 3yy + y^3$. From whence this ſeries may be derived.

$$1 . 1 . 1 . 7 . 25 . 97 . 373 . 1435 . 5521.$$

Therefore $y = \frac{1435}{5521}$; and $x = \frac{6946}{5521} = 1{,}2587$ nearly.

Again, let it be required to extract the biquadrate root of 20; then $x^4 = 20$, and ſuppoſing $x = y + 2$, we ſhall have $1 = \frac{8y + 6yy + 2y^3 + \frac{1}{4}y^4}{20}$; from whence this ſeries is obtained

$$0 . 0 . 0 . 1 . 8 . 70 . 610 . 5316 . \frac{1}{4} . 46332.$$

This gives $y = \frac{21265}{185328}$ $\left(= \frac{53161}{46332}\right)$ and $x = 2\frac{21265}{185328}$.

Which root approaches very near to the truth; ſo that it is much to be doubted whether the ſame could be obtained ſo quickly, and ſo accurately, by any other method.

Suppoſe again, that the ſquare root of 26 were required. Then $x = 26$. Let $x = y + 5$. And $1 = 10y + yy$. Hence we have the ſeries

$$0 . 1 . 10 . 101 . 1020 . 10301 . 104030.$$

Therefore $y = \frac{10301}{104030}$; and $x = \sqrt{26} = 5\frac{10301}{104030} =$ $5 . 0990195\,0360$, differing only by unit from $5 . 0990195\,1359$, found by the common method.

In the caſe where the greateſt root of the *equation* is required, the like obſervations may be made, as when we ſeek the leaſt root, viz. that we may obviate all inconveniences by ſuppoſing $x = \frac{1}{y} + s$. Both methods often take place without any preparation; ſometimes only one, and ſometimes neither; but this rarely. Both will ſucceed by a proper ſubſtitution of $x = y + s$, provided the *equation* have equal roots. To avoid fractions in both caſes, ſuppoſe, firſt, the general *equation* $ax^n = bx^{n-1} + cx^{n-2} + dx^{n-3} +$, &c. where a, b, c, d, &c. are integers; to which form all *equations* may be reduced. Then we avoid fractions by ſuppoſing $x = \frac{y}{a}$. In the ſecond method, we have the general *equation* $ax^n = bx^{n-1} + cx^{n-2} + \ldots + s$, where we may put $x = \frac{y}{a}$; but this ſubſtitution may often be well omitted.

It is to be obſerved, that this method may be ſometimes uſefully extended to literal *equations*. Thus in the general cubic *equation*, $1 = ax + bxx + cx^3$, form the ſeries $0 . 0 . 0 . 1 . a . aa + b . a^3 + 2ab + c . a^4 + 3aab + 2ac + bb . a^5 + 4a^3b + 3aac + 3abb + 2bc$, &c. then will the proximate value of $x = \frac{a^3 + 3aab + 2ac + bb}{a^4 + 4a^3b + 3aac + 3abb + 2bc}$.

The learned author of theſe methods afterwards applied them to the reſolution of infinite *equations*; for which we muſt refer the reader to the Acta Petropoli. tom. v. p. 63. 87.

The ingenious Mr. Simpſon gives us the following method for the ſolution of *equations* in numbers, when only one *equation* is given, and one quantity (x) to be determined.

Take the fluxion of the given *equation*, ſuppoſing x to be the variable quantity; and having divided the whole by x, let the quotient be repreſented by A. Eſtimate the value of x pretty near the truth, ſubſtituting the ſame in the *equation*, as alſo the value of A, and let the error, or reſulting number in the former, be divided by this numerical value of A, and the quotient be ſubtracted from the ſaid former value of x; and from thence will ariſe a new value of that quantity, much nearer the truth than the former, wherewith proceeding as before, another new value may be had, &c. till we arrive at any degree of accuracy deſired.

For inſtance, ſuppoſe, $300x - x^3 - 1000 = 0$. To find x, take the fluxion of the given *equation*, and expunging x, we have, $300 - 3xx = A$. It appearing, by inſpection, that $300x - x^3$, when $x = 3$, will be leſs, and when $x = 4$, will be greater than 1000, eſtimate x at 3.5, and ſubſtitute it inſtead thereof both in the *equation*, and in the value of A. The error in the former $= 7.125$, and the value of the latter $= 263.25$; wherefore taking $\frac{7.125}{263.25} = 0.027$ from 3.5, there remains 3.473 for a new value of x. With this proceeding as before, the next error, and the next value of A will be 0.0902518 and 263.815 reſpectively. Hence the third value of $x = 3.473963515$, which is true to 7 or 8 places.

The propoſed *equation* need not always be delivered from radicals, though this be ſometimes convenient, yet it is alſo ſometimes inſupportably tedious. Thus, if we had the *equation* $\sqrt{1 - x} + \sqrt{1 - 2x} + \sqrt{1 - 3x} - 2 = 0$; the clearing it from ſurds would be very tedious; but Mr. Simpſon's method gives the root without any previous reduction.

The like is to be obſerved, when two *equations* are given, and as many unknown quantities (x and y) are to be determined. For all which we refer to the author himſelf, in his Eſſays, printed 1740, p. 82, ſeq.

The old method of Vieta, for ſolving affected *equations*, was extremely tedious. It was formed by analogy, from the common method of extracting the roots of pure powers. See Vietæ Oper. Math. ap. Elzev. p. 163. or Wallis's Algebra, Oughtred's Clavis, De Lagny Elemens d'Arith. & d'Algebr. p. 525, &c.

Equations are conſidered two ways: either as the ultimate concluſions we arrive at in the ſolution of problems; or as means, by the help whereof, we arrive at thoſe final ſolutions.

An *equation* of the firſt kind conſiſts only of one unknown quantity, which is intermixed with other known quantities. Thoſe of the latter kind conſiſt of ſeveral unknown quantities, which are to be compared, and connected together, till out of them all ariſe a new *equation*, wherein there is but one unknown quantity mixed with the known. To obtain the value of which unknown quantity, the *equation* is generally turned, and tranſformed various ways, till it be brought as low, and rendered as ſimple, as poſſible.

The doctrine and practice of *equations*, that is, the ſolution of queſtions by *equations*, conſiſts of ſeveral ſteps, or parts; viz. 1. The denominating of the ſeveral quantities,

ties, or expreſſing them in proper ſigns, or ſymbols. 2. The bringing of the quantities thus denoted to an *equation*. 3. The reducing of that *equation* to its loweſt and ſimpleſt terms. To which, 4. May be added the conſtructing of the *equation*, or repreſenting it in geometrical lines.

With regard to the firſt; a queſtion, or problem, being propoſed, we conceive the thing ſought or required, as already done; and accordingly note or expreſs it by one of the laſt letters of the alphabet, *x*, *y*, or *z*; noting the other known quantities by the firſt letters of the alphabet, *a*, *b*, *c*, &c.

The queſtion being thus ſtated in ſpecies, it is conſidered whether, or no, it be ſubject to any reſtrictions, i. e. whether it be determinate, or no; which is found by three rules.

1. If the quantities ſought be more than the number of *equations* given, or contained in the queſtion, it is indeterminate, and capable of innumerable ſolutions. The *equations* are found, if they be not expreſly contained in the problem itſelf, by the theorems of the equality of quantities.

2. If the *equations* given, or contained in the problem, be juſt equal in number to the unknown quantities, the queſtion is determinate, or admits but of a limited number of anſwers.

3. If the unknown quantities be fewer than the given *equations*, the queſtion is yet more limited; and ſometimes it diſcovers itſelf impoſſible, by ſome contradiction between the *equations*. See REDUCTION *of equations*.

Now, *to bring a queſtion to an* EQUATION, that is, to bring the ſeveral mediate *equations* to one final one, the principal thing to be attended to, is to expreſs all the conditions thereof by ſo many *equations*. In order to which it is to be conſidered, whether the propoſitions or ſentences, wherein it is expreſſed, be all of them fit to be noted in algebraic terms; as our conceptions uſe to be in Latin, or Greek characters. And if ſo, as is generally the caſe in queſtions about numbers, or abſtract quantities, then let names be given both to known and unknown quantities, as far as occaſion requires; and thus the *draft* of the queſtion will be couched, as we may call it, in the *algebraical language*; and the conditions, thus tranſlated to algebraic terms, will give as many *equations* as are neceſſary to ſolve it. To illuſtrate this by an inſtance: ſuppoſe it required to find three numbers, in continual proportion, whoſe ſum is 20, and the ſum of their ſquares 140; putting *x*, *y*, *z*, for the names of the three numbers ſought, the queſtion will be tranſlated out of the verbal to the ſymbolical expreſſion, thus:

The queſtion in words.	*In ſymbols.*
Required three numbers, on theſe conditions:	*x*, *y*, *z* ?
That they be continually proportional.	$x.y :: y.z$, or $xz=yy$
That the ſum be 20.	$x+y+z=20$.
And the ſum of their ſquares 140	$xx+yy+zz=140$.

Thus is the queſtion brought to theſe *equations*, viz. $xz=yy$, $x+y+z=20$, and $xx+yy+zz=140$, by the help whereof, *x*, *y*, and *z*, are to be found by the rules already laid down.

The ſolutions of queſtions are, for the moſt part, ſo much the more expedite and artificial, by how much the unknown quantities, you have at firſt, are the fewer. Thus, in the queſtion propoſed, putting *x* for the firſt number, and *y* for the ſecond, $\frac{yy}{x}$ will be the third continual proportional; which being put for the third number, brings the queſtion into *equations*, as follows:

The queſtion in words.	*Symbolically.*
There are ſought three numbers in continual proportion.	$x, y, \frac{yy}{x}$
Whoſe ſum is 20.	$x+y+\frac{yy}{x}=20$.
And the ſum of their ſquares 140.	$xx+yy+\frac{y^4}{xx}=140$.

You have therefore the *equations* $x+y+\frac{yy}{x}=20$, and $xx+yy+\frac{y^4}{xx}=140$, by the reduction whereof, *x*, and *y*, are to be determined.

Take another example: a merchant increaſes his eſtate annually by one third part, ſpating 100*l.* which he ſpends yearly in his family; and after three years he finds his eſtate doubled. *Query*, what is he worth? To reſolve this, it muſt be obſerved, that their are (or ſhe hid) ſeveral propoſitions, which are all thus found out, and laid down:

In words.	*Algebraically.*
A merchant has an eſtate —	*x*
Out of which the firſt year he ſpends 100*l.*	$x-100$
And augments the reſt by one third —	$x-100+\frac{x-100}{3}$, or $\frac{4x-400}{3}$
And the ſecond year he ſpends 100*l.*	$\frac{4x-400}{3}-100$, or $\frac{4x-700}{3}$
And augments the reſt by one third	$\frac{4x-700}{3}+\frac{4x-700}{9}$, or $\frac{16x-2800}{9}$
And in the third year he ſpends 100*l.*	$\frac{16x-2800}{9}-100$, or $\frac{16x-3700}{9}$
And by the reſt gains likewiſe one third.	$\frac{16x-3700}{9}+\frac{16x-3700}{27}$, or $\frac{64x-14800}{27}$
And he becomes in length twice as rich as at firſt.	$\frac{64x-14800}{27}=2x$

Therefore the queſtion is brought to this *equation*, $\frac{64x-14800}{27}=2x$, by the reduction whereof you will find the value of *x*.

Viz. Multiply it into 27, and you have $64x-14800=54x$; ſubtract $54x$, and there remains $10x-14800=0$, or $10x=14800$; and dividing by 10, you have $x=1480$. So that the value of his eſtate at firſt was 1480*l.*

It appears then, that to the ſolution of queſtions about numbers, or the relations of abſtract quantities, there is ſcarce any thing more required, but to tranſlate them out of the common tongue into the algebraic language, i. e. into characters, proper to expreſs our ideas of the relations of quantities. Indeed, it may ſometimes happen, that the language wherein the queſtion is ſtated, may ſeem unfit to be rendered into the algebraical; though by making a few alterations therein, and attending to the ſenſe, rather than the ſound of the words, the tranſlation becomes eaſy enough. The difficulty here reſults merely from the difference of idioms, which is as obſervable between moſt languages as between the common and ſymbolical. However, to render the *ſolution* of ſuch problems a little more eaſy and familiar, we ſhall add an example or two of them.

1. *Given the ſum of two numbers a, and the differenc of the ſquares b; to find the numbers themſelves.* Suppoſe the leſſer, *x*; the other will be $x+a$; and their ſquares xx and $aa+2ax+xx$, whoſe difference, $aa+2ax$ is called *b*. Conſequently, $aa+2ax=b$. Whence, by reduction, $aa-b=2ax$, or $\frac{aa-b}{2a}\left(=\frac{1}{2}a-\frac{b}{2a}\right)=x$.

E. gr. Suppoſe the ſum of the numbers, or *a*, to be 8, and the difference of their ſquares, or *b*, 16; then will $\frac{1}{2}a-\frac{b}{2a}(=4-1)=3=x$. And $a-x=5$. Therefore the numbers are 3 and 5.

2. *To find three quantities, x, y, and z, the ſum of each pair whereof is given.* Suppoſe the ſum of the pair *x* and *y* be *a*; that of *x* and *z*, *b*; and that of *y* and *z*, *c*. To determine the three numbers required, *x*, *y*, and *z*, we have three *equations* $x+y=a$, $x+z=b$; and $y+z=c$. Now, to exterminate two of the unknown quantities, e. gr. *y* and *z*, take away *x*, both from the firſt and ſecond *equations*, and we ſhall have $y=a-x$, and $z=b-x$. Which values being ſubſtituted for *y* and *z* in the third *equation*, there will ariſe $a-x+b-x=c$; and by reduction $x=\frac{a+b-c}{2}$. Having found *x*, the former *equations*, $y=a-x$, and $z=b-x$, will give *y* and *z*.

Thus, e. gr. if the ſum of the pair *x* and *y* be 9; of *x* and *z*, 10; and of *y* and *z*, 13; then, in the value of *a*, *y*, and *z*, write 9 for *a*, 10 for *b*, and 13 for *c*; and you will have $a+b-c=6$; and conſequently $x\left(=\frac{a+b-c}{2}\right)=3$, $y\left(=a-x\right)=6$, and $z\left(=b-x\right)=7$.

3. *To divide a given quantity into any number of parts, ſo as that the greater parts ſhall exceed the leaſt by any given difference.* Suppoſe *a* to be a quantity which is to be divided into four ſuch parts, the firſt and ſmalleſt whereof is *x*; the excels of the ſecond part above this, *b*, of the third *c*, and the fourth *d*; then will $x+b$ be the ſecond part, $x+c$ the third, and $x+d$ the fourth; the aggregate of all which $4x+b+c+d$ is equal to the whole line *a*. Now, taking away from each, $b+c+d$, and there remains $4x=a-b-c-d$, or $x=\frac{a-b-c-d}{4}$.

Suppoſe, e. gr. a line of 20 feet to be divided into 4 parts, in ſuch manner, as that the excels of the ſecond above the firſt may be 2 feet, of the third 3 feet, and of the fourth 7 feet. Then the four parts will be $x\left(=\frac{a-b-c-d}{4}, \text{or } \frac{20-2-3-7}{4}\right)=2$, $x+b=4$, $x+c=5$,

$c=5$, and $x+d=9$. And after the same manner, may a quantity be divided into a greater number of parts on the like conditions.

4. *A person disposed to distribute a little money among three beggars, wanted 3d. to pence of their pence for each of them: he therefore gives them two pence-a-piece, and has three pence left: the number of beggars is required.* Let the number of beggars be called x; and the person wants δ pence of giving them all $3x$ pence. Consequently he has $3x-\delta$; out of which he gives $2x$ pence; and the remaining pence $+3x-\delta-2x=3$. That is, $x-\delta=3$, or $x=\delta+3$.

5. *The power or strength of one agent being given, to determine how many such agents will produce a given effect in a given time b.* Suppose the power of the agent such, as that it may produce the effect c, in the time d; then as the time d is to the time b, so is the effect c, which the agent can produce in the time d, to the effect it can produce in the time b, which accordingly will be $\frac{bc}{d}$. Then, as the effect of one agent $\frac{bc}{d}$ is to the joint effect of them all, a; so is that one agent, to all the agents. Consequently the number of agents will be $\frac{ad}{bc}$.

Thus, e. gr. if a clerk, or writer, in 8 days time transcribe 15 sheets; how many such clerks are required to transcribe 405 sheets in 9 days? *Ans.* 24. For if 8 be substituted for d, 15 for c, 405 for a, and 9 for b, the number $\frac{ad}{bc}$ will become $\frac{405\times8}{9\times15}$, that is $\frac{3240}{135}$, or 24.

6. *The powers of several agents being given; to determine the time x, wherein they will jointly perform a given effect.* Suppose the powers of the agents, A, B, C, such as that in the times c, f, g, they would produce the effects a, b, c, respectively; and these, in the time x, would produce effects $\frac{ax}{c}$, $\frac{bx}{f}$, $\frac{cx}{g}$. Consequently $\frac{ax}{c}+\frac{bx}{f}+\frac{cx}{g}=d$, and by reduction $x=\frac{d}{\frac{a}{c}+\frac{b}{f}+\frac{c}{g}}$.

Suppose, e. gr. that three workmen could finish a certain work in such and such times, viz. A once in three weeks, B thrice in eight weeks, and C five times in twelve weeks; and it is required in what time they will finish it together? Here, the powers of the agents A, B, C, are such as in the times 3, 8, and 12, respectively produce effects 1, 3, 5; and it is required in what time they will produce the effect together. For a, b, c, d, e, f, g, write 1, 3, 5, 1, 3, 8, 12; and there will come out $x=\frac{1}{\frac{1}{3}+\frac{3}{8}+\frac{5}{12}}$, or $\frac{1}{2}$ of a week, that is, 6 days, 5½ of an hour, the time they will finish it in together.

7. *Given the specific gravities of a mixture, and of the several ingredients thereof; to find the proportion of the ingredients therein.* Suppose e the specific gravity of the mixture $A+B$; a that of A, and b that of B; since the absolute gravity, or weight, is compounded of the bulk of the body, and its specific gravity; a A will be the weight of A, b B, that of B; and e A+e B the weight of the aggregate A+B. Consequently, a A+b B=e A+e B; and therefore a A−e A = e B−b B, or $e-b:a-e::$ A : B. Thus, e. gr. suppose the specific gravity of gold to be as 19, that of silver as 10½, and that of king Hiero's crown, composed of gold and silver, as 17½; then will A : B :: $e-b:a-e::17\frac{1}{2}-10\frac{1}{2}:19-17\frac{1}{2}::7-5\frac{1}{2}:2::20:6\frac{2}{7}::10:3$: the bulk of gold in the crown, to the bulk of silver; or $19\frac{2}{7}:3\frac{1}{7}$ (:: $19\times10:10\frac{1}{2}\times3::a\times e-b:b\times a-e$) :: the weight of the gold in the crown, to the weight of the silver, and $221:31$ :: the weight of the crown to the weight of silver. See ALLIGATION and HIERO's crown.

Dr. Halley's method for the solution of *equations* is thus: Let the root x of any *equation* be taken equal to $a\pm e$, where a is supposed to be taken near to the true value. Then from the quantity $a\pm e$ let all the powers of e, found in the proposed *equation*, be formed, and to these let their respective coefficients be prefixed. Let the power to be resolved be subducted from the sum of the parts of the first column where e is not found; and let the difference be $+b$. Then take the sum of all the coefficients of e in the second column, which call $+f$; and having added all the coefficients of e^2, the sum of which be called $+g$, the root sought x, will, in a rational form, $=a+\frac{+b}{+f+g}$; and, in an irrational form, $=a+\frac{+b}{+f+g\pm\sqrt{f^2+2bg+b^2}}$.

For instance, let it be supposed to find a root of the *equation* $x^3-3ax^2+7a^2x=10000$, where 10000 is the resolvend.

For the first supposition let $a=10$; we shall therefore have the *equation*

$$\begin{array}{l} x^3=a^3\pm3ae^2\pm3a^2e+e^3\pm3ae^2\pm3a^2e+e^3\\ -3ax=-3a^2\pm3ae-3ae\\ +7a^2=+7a^2\pm7e^2\\ =10000\pm1000e\pm600e^2\pm30e^3+e^3\\ -300\pm60e-3e^2\\ +700\pm7e^2\\ =10000\\ +450\mp40\,15e+5\,97e^2\pm40e^2+e^3=0\end{array}$$

The signs + and −, with respect to e and e^2, are left doubtful, till it be known whether a be affirmative or negative; in which these is some difficulty, as the roots having several rents, the *homogeneous* compositions are called, are often increased by diminishing, and the contrary, diminished by increasing a. The sign of e is determined by the sign of the quantity resolvend being subtracted from the sum of the parts from a, the sign of e^2, and therefore of the parts prevailing in its composition, will always be contrary to the sign of the difference b. Hence it will appear whether a be affirmative or negative, or whether a has been assumed greater or less than the true root. But $\frac{+b}{+f\pm g}$ is always equal to $\frac{+b}{f}\mp\frac{bg}{f^3}+\frac{2bg^2}{f^5}-\frac{5b^2g^3}{f^7}$, &c. as often as g and f have the same sign; but when they are connected with different signs, e becomes $=\frac{\sqrt{f^2+2bg-b^2}}{f}-\frac{b}{f}$. After that e has been found to be negative, e, e^2, e^3, &c. must be made negative in the affirmative members of the *equation*, and affirmative in the negative members; that is, they must be writ with a contrary sign; but if e be affirmative, then must e, e^2, e^3, &c. be affirmative in the affirmative members, and negative in the negative.

In the proposed example we have 10450 instead of the resolvend 10000, or $b=+450$; from whence it appears that a was taken greater than the true root; and consequently that e is negative. Hence the equation becomes $10450-4015e+597e^2+40e^2+e^3=10000$, that is, $450-4015e+597e^2=0$. Therefore, $450=4015e-597e^2$, or $b=4015e-597e^2$; the root of which is $e=\frac{2007\frac{1}{2}-\sqrt{4027\frac{1}{4}-597b}}{597}$, or $\frac{\frac{1}{2}}{2f}-\sqrt{\frac{1}{4f^2}-\frac{b}{597}}$, that is, in the present case, $e=\frac{2007\frac{1}{2}-\sqrt{3761\frac{1}{4}}}{597}$, from whence the approximated root is found to be $=0.886$. Now this root being taken for a second supposition, and the operation being repeated, we shall have $a+e=9.886050597=a$, which is very exact, scarce exceeding the truth by above 2 in the 8th figure.

This is sufficient to give a notion of Dr. Halley's method: those who desire more examples, and further instructions may consult the Phil. Trans. N° 210. or Lowthorp's Abridg. vol. i. p. 85. seq.

EQUATION, *differential*. See DIFFERENTIAL.

EQUATION, *to bring geometrical problems to*. Geometrical questions, or those relating to continued quantities, are sometimes also brought to *equations*, after the same manner as arithmetical ones. So that the full rule to be here prescribed is, to observe every thing directed for the solution of numerical problems.

Suppose, e. gr. it were required to cut a right line, as A B (*Vide Algebra fig.* 6.) in mean and extreme proportion in C; that is, so as that B E, the square of the greater part, shall be equal to the rectangle B D, contained under the whole and the leſſer part.

Here supposing A B=a, and C B=x; then will A C=$a-x$; and $a\times a-x=x^2$. An *equation* which, by reduction, gives $x=-\frac{1}{2}a+\sqrt{\frac{1}{4}a^2}$.

But it is very rare that geometrical problems are thus brought to *equations*; as being generally found to depend on various complex positions, and relations of lines; so that here some farther artifice, and certain special rules, will be required, to bring them to algebraic terms. Indeed, it is very difficult to prescribe any thing peculiar in such cases; every man's own genius should be the rule of his procedure.

Something, however, shall be said in the general, for the sake of such as are not at all versed in such operations, and that principally from Sir Isaac Newton.

Observe then, 1. That problems concerning lines related to each other in any definite manner, may be rationally stated, by supposing such or such quantity, or things sought, to be required from such and such data; yet still, with whatever data and quæsita the question is propared, its solution, will arise after the very same manner, without the least alteration of any circumstance, except in the imaginary species of lines, or in the names whereby the data are distinguished from the quæsita.

Suppose, e. gr. the question were about an isoceles triangle, BCD (*fig.* 7.) inscribed in a circle, whose sides BC, BD, and base CD, were to be compared with the diameter of the circle AB. Here the question may be either proposed, of investigating the diameter from the given sides and base, or investigating the base from the sides and diameter given. Or, lastly, of finding the sides from the base and diameter given; and propose it under which form you will, it will be brought to an *equation*, by the same algebraic series.

Thus, if the diameter be sought, put AB = *x*, CD = *a*, and BC, or BD = *b*. Then, drawing AC, as the triangles ABC and CBE are similar; AB : BC :: BC : BE, or $x : b :: b : BE$. Wherefore $BE = \frac{bb}{x}$, and $CE = \frac{1}{2}CD$, or $\frac{1}{2}a$. And because the angle CEB is a right angle, $CE^2 + BE^2 = BC^2$, that is, $\frac{1}{4}aa + \frac{b^4}{xx} = bb$. Which *equation* being reduced, gives the diameter required, *x*. Again, if the base be sought, put AB = *c*, CD = *x*, and BC, or BD = *b*. Then drawing AC, as the triangles ABC and CBE are similar; AB : BC :: BC : BE, or $c : b :: b : BE$. Wherefore $BE = \frac{bb}{c}$. And $CE = \frac{1}{2}CD$, or $\frac{1}{2}x$. And since the angle CEB is right, $CE^2 + BE^2 = BC^2$, that is, $\frac{1}{4}xx + \frac{b^4}{cc} = bb$; an *equation* which, reduced, gives the base sought, *x*.

Lastly, if the side BC, or BD, were sought, put AB = *c*, CD = *x*, and BC, or BD = *x*. Then drawing AC, the triangles ABC, and CBE, being similar, we have AB : BC :: BC : BE, or $c : x :: x : BE$. Wherefore, $BE = \frac{xx}{c}$. And $CE = \frac{1}{2}CD$, or $\frac{1}{2}a$; and the angle CEB being right, $CE^2 + BE^2 = BC^2$. That is, $\frac{1}{4}aa + \frac{x^4}{cc} = xx$. An *equation* which, by reduction, gives *x* required.

Thus is the calculus for arriving at the *equation*, as well as the *equation* itself, the same in all the cases; except that the same lines are designed by different letters, according as they are data, or quæsita. Indeed, as the data or quæsita differ, there arises a difference in the reduction of the *equation* found; but there is no difference in the *equation* itself. So that we need make no difference between given and sought quantities; but are at liberty to state the question with such data and quæsita, as we think most favourable to the solution of the question.

3. A problem then being proposed, compare the quantities it includes; and, without making any difference between data and quæsita, consider what dependences they have on each other, that you may learn which of them will, by computation, give the rest: In the doing of which, it is not necessary you should at first perceive how some may be deduced out of others, by an algebraic calculus: it suffices you remark in the general, that it may be deduced by some direct connexion. Thus, e. gr. if the question be about the diameter of a circle, AD (*fig.* 8.) and three lines AB, BC, CD, inscribed in a semicircle, whereof, the rest being given, BC is required: it is evident, at first sight, that the diameter AD determines the semicircle; as also, that the lines AB and CD, by inscription, determine the points B and D, and consequently BC required, and that by a direct connexion. Yet does not it appear how BC is deduced from the same data, by any analytical calculus.

4. Having considered the several ways wherein the terms of the question may be explained and compounded, choose some of the synthetic methods; assuming some lines, as given, from which there is the most easy access, or progression to the rest, and to which the regression is the most difficult. For, though the calculus may be carried on diverse ways, yet must it begin with these lines; and the question is more readily solved, by supposing it to be of these data, and some quantities readily flowing from them, than by considering the question as it is actually proposed.

Thus, in the example already given, if from the rest of the quantities given, it were required to find AD; perceiving that this cannot be done synthetically; yet that if it were so done, I could proceed in my reasoning on it in a direct connexion from one thing to others. I assume AD as given, and begin to compute as if it was really given, and some of the other quantities, viz. some of the given ones, as AB, BC, or CD, were sought; and thus, by carrying on the computation, from the quantities assumed to the others, as the relations of the lines to one another are, there will always be obtained an *equation* between two values of some one quantity; whether one of those values be a letter set down as a representation, or name, at the beginning of the work, for that quantity; and the other, a value of it found out by computation; or whether both be found by computation made different ways.

5. Having thus compared the terms of the question in general, there is some farther thought and address required, to find the particular connexions, or relations of the lines, fit for computation. For those quantities which, to a person who does not so thoroughly consider them, may seem immediately, and by a very near relation, connected together, when we come to express that relation algebraically, are often found to require a longer circuit, and shall even oblige you to begin your schemes anew, and carry on your computation step by step, as may appear by finding BC, from AD, AB, and CD. For you are only to proceed by such propositions, or enunciations, as can be fitly represented in algebraic terms, wherein if there are several arising from Euclid, as, 19. prop. 4. book vi. and prop. 47. lib. 1. Elem.

To facilitate this discovery, of the relations of the lines in the figure, there are several things that contribute; as first, the addition and subtraction of lines; since from the values of the parts you may find the value of the whole; or from the value of the whole, and one of the parts, you may obtain the value of the other part. Secondly, by the proportionality of lines; since, as above supposed, the rectangle of the mean terms, divided by either of the extremes, gives the value of the other; or which is the same thing, if the values of all four of the proportionals be first had, we make an equality (or *equation*) between the rectangles of the extremes and means. But the proportionality of lines is best found out by the similarity of triangles; which, as it is known by the equality of their angles, the analyst ought in particular to be conversant in. In order to which, it will be necessary that he be master of Euclid. prop. 5. 13. 15. 29. and 32. lib. 1. and of prop. 4. 5. 6. 7. 8. lib. 6. and of the 20, 21, 22, 27, and 32. lib. 3. To which may be added the 31 prop. lib. 6. or the 35th and 36th prop. lib. 3. Thirdly, the calculus is promoted by the addition or subtraction of squares; viz. in right-angled triangles we add the squares of the leſſer sides, to obtain the square of the greater; or from the square of the greater side we subtract the square of one of the leſſer, to obtain the square of the other. On which few foundations, if we add to them prop. 1. of the 6th Elem. when the business relates to superficies, and also some propositions taken out of the eleventh and twelfth books of Euclid, when solids come in questions, the whole analytic art, as to right-lined geometry, depends. Indeed all the difficulties of problems may be reduced to the sole composition of lines out of parts, and the similarity of triangles; so that there is no occasion to make use of other theorems, because they may all be resolved into these two, and consequently into the solutions that may be drawn from them.

6. To accommodate these theorems to the solutions of problems, the schemes are oft times to be farther constructed, by producing out some of the lines, till they cut some others, or become of an assigned length; or by drawing lines parallel or perpendicular, from some remarkable points; or by conjoining some remarkable points; as also, sometimes, by constructing them after other methods, according as the state of the problems and the theorems, which are made use of to solve it, shall require.

As for example: if two lines that do not meet each other, make given angles with a certain third line, we may produce them so, that when they concur, or meet, they shall form a triangle, whose angles, and consequently the ratio of their sides, shall be given, or if any angle be given, or be equal to any one, we often compleat it into a triangle given in specie, or similar to some other, and that by producing some of the lines in the scheme, or by drawing a line subtending an angle. If the triangle be an obliquangled one, we often resolve it into two right-angled ones, by letting fall a perpendicular. If the business concern multilateral or many-sided figures, we resolve them into triangles, by drawing diagonal lines, and so in others; always aiming at this end, viz. that the scheme may be resolved either into given, or similar, or right-angled triangles.

Thus, in the example proposed, draw the diagonal BD, that the trapezium ABCD may be resolved into two triangles, ABD, a right-angled one, and BDC an oblique angled one (*fig.* 8.); then resolve the oblique angled one into two right-angled triangles, by letting fall a perpendicular from any of its angles, B, C, or D, upon the opposite side; as from B upon CD produced to E, that BE may meet it perpendicularly. But since the angles BAD and BCD, make in the mean while two right ones (by 22. prop. 3. Euclid.), as well as BCE and BCD, the angles BAD and BCE are perceived to be equal; consequently the triangles BCE and DAB to be similar,

similar. And so the computation (by assuming AD, AB, and BC, as if CD were sought) may be thus carried on; viz. AD and AB (because of the right-angled triangle ABD) give you BD. AD, AB, BD, and BC (because of the similar triangles ABD and CEB) give BE and CE. BD and BE (because of the right-angled triangle BED) give ED; and ED—EC gives CD; whence there will be obtained an *equation* between the value of CD so found out, and the algebraic letter that denotes it. We may also send for the given part as is better to do, than to follow the work too far to one continued series) begin the computation from different principles, or at least promote it by divers methods, to one and the same conclusion, that at length there may be obtained two values of any of the same quantity, which may be made equal to one another. Thus AD, AB, and BC, give BD, BE, and CE, as before; then CD + CE gives ED; and lastly, DB, and ED (because of the right-angled triangle BED) give BE.

7. Having concerted your method of procedure, and drawn your scheme, give names to the quantities that enter the computation (that is, seem which assumed, the values of others are to be derived, till you come to an *equation*) choosing such as involve all the conditions of the problem, and seem best accommodated to the business, and which may render the conclusion (as far as you can guess) more simple, but yet not more than what shall be sufficient for your purpose; wherefore do not give new names to quantities which may be nominated from names already given. Thus, of a whole line given, and its parts, of the three sides of a right-angled triangle, and of three or four proportionals, some one of the least considerable we leave without a name; because its value may be derived from the names of the rest. As in the example already brought, if I make AD = *a*, and AB = *b*, I denote BD by no letter, because it is the third side of a right-angled triangle ABD, and consequently its value is $\sqrt{aa-bb}$. Then if I say BC = *c*, since the triangles DAB and BCE are similar, and thence the lines AD : AB :: BC : CE, to three wherof, viz. to AD, AB, and BC, there are already names given; for that reason I leave the fourth CE without a name, and in its room I make use of $\frac{ab}{a}$, discovered from the foregoing proportionality. And so if DC be called *c*, I give no name to DE, because from its parts DC and CE, or *c* and $\frac{ab}{a}$, its value $c+\frac{ab}{a}$ comes out.

8. By this time the problem is almost reduced to an *equation*. For after the aforesaid letters are set down from the species of the principal lines, there remains nothing else to be done, but that out of those species the values of other lines be made out, according to a pre-conceived method, till after some foreseen way they come to an *equation*. And there is nothing wanting in this case, except that by means of the right angled triangles BCE and BDE, I can bring out a double value of BE, viz. $BC^2 - CE^2 \left(\text{or } bb - \frac{aabb}{aa} \right) = BE^2$; as also $BD^2 - DE^2 \left(\text{or } aa - 2ac - cc - \frac{2abc}{a} - \frac{aabb}{aa} \right) = BE^2$. And hence (expunging on both sides $\frac{aabb}{aa}$) you shall have the *equation* $bb = aa - 2ac - cc - \frac{2abc}{a}$; which being reduced, becomes $x^2 = +2ax + bb + 2abc + cc$.

9. For the geometry of curve lines: we denote them either in describing them by the local motion of right lines, or by using *equations* indefinitely expressing the relation of right lines disposed in order, according to some certain law, and ending at the curve lines. See CONIC *Sections*.

The ancients did the same by the sections of solids; but they effected it less commodiously. The computations which regard curves, described after the first manner, are performed as above directed: thus suppose AKC (*fig.* 9.) a curve line, described by K, the vertical point of the right angle AKs, whereof one leg, AK, freely slides through the point A given in position, while the other Ks of a determinate length is carried along the right line AD, also given in position; and it is required to find the point C, in which any right line CD, given also in position, shall cut this curve: draw the right lines AC, CF, which may represent the right angle in the position sought, and CB perpendicular to AF, and the relation of the lines (without any difference or regard of what is given or sought, or any respect had to the curve) being considered, you perceive the dependency of the others upon CF, and any of these four, viz. BC, BF, AF, and AC, to be synthetical; two whereof you assume as CF = *x*, and CB = *y*, and beginning the computation from thence, you presently obtain $BF = \sqrt{aa - xx}$, and $AB = \frac{xx}{\sqrt{aa-xx}}$, because of the right angle CBF; and that the lines BF : BC :: BC : AB are continual proportionals. Moreover, from the given position of CD, AD is given, which therefore call *a*; there is also given the ratio of BC to BD, which suppose as *d* to *e*, and you have $BD = \frac{ey}{d}$, and $AB = b - \frac{ey}{d}$.

Therefore $b - \frac{ey}{d} = \frac{xx}{\sqrt{aa-xx}}$, an *equation* by squaring its parts, and multiplying by $aa -$ will be reduced to this form.

$$x^4 = \frac{2bdex^3 + e^2x^2 - b^2d^2x^2 - 2abde x + a^2d^2}{dd + ee}$$

Whence, lastly, from the given quantities, *a*, *b*, *d*, and *e*, *x* may be found; and at that intersal, or distance, or BC, a right line drawn parallel to AD will cut CD in the point sought, which is C.

If, instead of geometrical description, we use *equations* to denote the curve lines by, the computations will thereby become as much shorter and easier, as the gaining of those *equations* can make them. Thus, suppose the intersection C of the given ellipis ACE, (*fig.* 10.) with the right line CD given in position, sought; to denote the ellipsis, take some known *equation* proper to it, as $rx - \frac{r}{q}xx = yy$, where *x* is indefinitely put for any part of the axis Ab, or AB, and *y* for the perpendicular bC, or BC, terminated at the curve; and *r* and *q* are given for the given species of the ellipsis. Since therefore CD is given in position, AD will also be given, which call *a*, and BD will be $a - x$; also the angle ADC will be given, and thence the ratio of BD to BC, which call *e* to *d*; and BC (*y*) will be $= \frac{ex}{d} - \frac{ea}{d}$, whose square $\frac{eexx}{dd} - \frac{2eeax}{dd} + \frac{eeaa}{dd}$, will be equal to $rx - \frac{r}{q}xx$. And thence by reduction there will arise $xx = \frac{2aecx + rq - 2aqcc}{ee + \frac{r}{q}}$, or $x = \frac{aec + \frac{1}{2}rq \pm e\sqrt{ar + \frac{rr}{4cc} - \frac{aqr}{q}}}{ee + \frac{r}{q}}$. Add, that tho' a curve be denominated by a geometrical description, or by a section of a solid, yet thence an *equation* may be obtained, which shall define the nature of the curve, and consequently all the difficulties of problems proposed about it, may be reduced hither. Thus, in the former example, if AB be called *x*, and BC, *y*, the third proportional BF will be $\frac{yy}{x}$, whose square, together with the square BC, is equal to CF^2, that is, $\frac{y^4}{xx} + yy = aa$; or $y^4 + xxyy = aaxx$. And this is an *equation*, by which every point C, of the curve AKC, agreeing or corresponding to any length of the base and consequently the curve itself, is defined, and from whence consequently you may obtain the solutions of problems proposed concerning this curve.

After the same manner almost, when a curve is not given in specie, but proposed to be determined, you may feign an *equation* at pleasure, that may contain its general nature; and assume this to denote it, as if it was given; that from its assumption you may come way arrive at *equations*, by which the assumptions may be determined.

What remains of the doctrine and practice of *equations*, relates to their reduction to the lowest and simplest terms, the better to come at the value of the unknown quantity in the *equation*, and their geometrical construction. See REDUCTION *of equations*.

EQUATIONS, *construction of*. See CONSTRUCTION *of equations*, and CURVE.

EQUATIONS, *converse of*. See CONVERSION.

EQUATIONS, *affected, eliminated, exponential, and transcendental*. See the adjectives.

EQUATION *of payments*, in *Arithmetic*, is the method of reducing several debts payable at different times, and bearing no interest till after the term of payment to a single debt or payment, to be discharged at once, without loss either to debtor or creditor, allowing simple interest; or, it is the method of finding the equated term at which

these several debts should be paid in one sum. Cocker, Hatton, Kersey, sir Samuel Moreland, and Ward, have given rules for this purpose, which Mr. Malcolm has examined and found to be erroneous; and though the error resulting from any of the rules which they have proposed is not very considerable, the following process furnishes one more accurate:

Let the debt first payable be called d. The last payable debt D
The distance of the term of payment d. The distance of the term T
The distance of the equated time x
The rate of interest, or 1 year's interest of 1*l.* r
The distance of the time t and x is $x-t$ } for x less be-
The distance of the time T and x is $T-x$ } tween them.

Then the interest of d for the time $x-t$ is $dr \times x-t$, or $drx-drt$, dr being one year's interest of d; and $\frac{Dr-Drx}{1+Tr-rx}$ is the discount of D for the time $T-x$, because $Tr-rx$ is the interest of 1*l.* for that time, which is consequently the discount of $1+Tr-rx$ for the same time; consequently, from the nature of the question, we shall have $drx-drt=\frac{Dr-Drx}{1+Tr-rx}$; which, being reduced, gives $T+t+\frac{D+d}{dr}\times x-x^2=\frac{DT+dt}{dr}+Tt$. Then make $T+t+\frac{D+d}{dr}=a$, and $\frac{DT+dt}{dr}+Tt=s$, and $ax-x^2=s$; and, resolving this quadratic equation, $x=\frac{a}{2}\pm\sqrt{\frac{a^2}{4}-s}$.

E. gr. Suppose 100*l.* payable one year hence, and 105*l.* payable three years hence; what is the equated time, allowing simple interest at 5 *per cent. per annum*?

Here $d=100$ $D=105$ $r=.05$.
$t=1$ $T=3$

Then $D+d=205$, $dr=5$, and $\frac{D+d}{dr}=\frac{205}{5}=41$

And $T+t+\frac{D+d}{dr}$, or $a=4+41=45$.

And s or $\frac{DT+dt}{dr}+Tt=\frac{315+100}{5}+3=83+3=86$.

Consequently,

$x=\frac{45}{2}\pm\sqrt{\frac{2025}{4}-86}=\frac{45}{2}\pm\sqrt{506.25-86}=22.5\pm\sqrt{420.25}=22.5\pm20.5=43$ or 2: but 43 cannot be the true answer by the conditions of the question, since it is greater than the distance of the last term in the question; and therefore 2 is the answer required.

If there are more debts than two, you must first find an equated time for the two that are first payable; then consider their sum as a debt payable at that equated time, and find another equated time for that debt and the next of the given debts, &c. See Malcolm's Arithm. book vi. § 5. or p. 616—621.

EQUATION *of time*, in *Astronomy*, denotes the difference between mean and apparent time, or the reduction of the apparent unequal time or motion of the sun or a planet, to equable and mean time, or motion.

Time is only measured by motion; and as time in itself flows ever equably, to measure it, such a motion must be used as is equable, or which always proceeds at the same rate.

The motion of the sun is commonly used for this purpose, as it is the most easy to be observed; yet it wants the great qualification of a chronometer, which is equability. In effect, the astronomers find, that the sun's apparent motion is no ways equal; that he now and then slackens his pace, and afterwards quickens it again; and consequently equal time cannot be measured thereby. See SUN.

Hence the time which the sun's motion shews, called the *apparent time*, becomes different from the true and equable time, shewn by a well-regulated clock, wherein all the celestial motions are to be estimated and accounted; so that the time shewn by such a clock and a true sun-dial is never the same, but on the 15th of April, the 16th of June, the 31st of August, and the 24th of December. See the annexed table.

This inequality of time is thus accounted for: the natural or solar day is measured not properly by one entire revolution of the equinoctial, or 24 equinoctial hours, but by the time which passes while the plane of a meridian, passing through the centre of the sun, does, by the earth's conversion round its axis, return again to the sun's centre, which is the time between one midday and the next.

Now, had the earth no other motion but that round its axis; all the days would be precisely equal to each other, and to the time of the revolution of the equinoctial; but the case is otherwise; for while the earth is turning round its axis, it is likewise proceeding forward in its orbit. So that when a meridian has completed a whole revolution from the sun's centre, its plane has not yet arrived at the sun's centre again, as will appear from the figure.

Let the sun be S (*Tab. Astron. fig.* 50); and let AB be a portion of the ecliptic; let the line MD represent any meridian, whose plane produced passes through the sun when the earth is in A. Let the earth proceed in its orbit; and in making one revolution round its axis, let it arrive at B; then will the meridian MD be in the position md parallel to the former MD; and consequently this has not yet passed through the sun, nor have the inhabitants under that meridian yet had their midday: but the meridian dm must still proceed with its angular motion, and describe the angle dBf before its plane can pass through the sun.

Hence, it appears that the solar days are all longer than the time of one revolution of the earth round its axis.

However, were the planes of all the meridians perpendicular to the plane of the earth's orbit, and did the earth proceed with an equal motion in its orbit, the angle dBf would be equal to the angle BSA, and the arches Af and AB would be similar; consequently, the times would be always equal, the arch AB, and the angle dBf, of the same quantity, all the solar days equal to each other, and the apparent and real time agree.

But as it is, neither of those is the case; for the earth does not proceed in its orbit with an equable motion; but in its aphelion describes a less arch, and in its perihelion a greater, in the same time; besides, the planes of the meridians are not perpendicular to the ecliptic, but to the equator; consequently, the time of the angular motion, dBf, which is to be added to the entire revolution in order to make a whole day, is not always of exactly the same quantity.

The same will be found, if setting aside the consideration of the real motion of the earth, we consider the apparent motion of the sun in lieu thereof, as being what we measure time by. On this principle we observe, that the day not only includes the time of one revolution of the globe on its axis, but it is increased by so much as answers to that part of the sun's motion performed in that time: for when that part of the equinoctial, which, with the sun, was at the meridian yesterday at noon, is come thither again to-day, it is not yet noon, the sun not being now at the place where he yesterday was, but gone forward near a degree, more or less; and this additament above the 24 equinoctial hours is upon a double account unequal.

1. In that the sun, because of his apogee and perigee, does not at all times of the year dispatch an equal arch of the ecliptic in one day, but greater arches near the perigæum, which, in the present century, is on the 30th of December; and lesser near the apogæum, which is on the 30th of June.

2. In that though the sun should always move equably in the ecliptic, yet equal arches of the ecliptic do not, in all parts of the zodiac, answer to equal arches of the equator, by which we are to estimate time, because some parts thereof, as the two solstitial points, lie nearer to a parallel position to the equinoctial than others, *e. gr.* those about the equinoctial points where the ecliptic and equinoctial intersect. Whereupon an arch of the ecliptic near the solstitial points answers to a greater arch of the equinoctial than an arch equal to it near the equinoctial points.

The apparent motion of the sun to the east then being unequal, the natural and apparent days are no ways proper to be applied to measure the celestial motions, which have no dependence on that of the sun.

And hence astronomers have been obliged to invent other days for the use of their calculations; those others are equal, and are a mean between the shortest and longest of the unequal ones.

These are had by considering the number of hours in the whole revolution of the sun in the ecliptic, and dividing the whole time into as many equal parts as there are hours, 24 of which constitute the day; and the reduction of the days constitutes the *equation* of natural days.

Consequently, computing these motions according to equal time, it is necessary to turn that time back again into apparent time, that they may correspond to observation: on the contrary, any phenomenon being observed, the apparent time thereof must be converted into equal time, to have it correspond with the times marked in the astronomical tables. As we do not know of any body in nature that moves equably, yet such a motion being alone proper to measure equal days and hours; it has been thought

fit to imagine ſome body, e. gr. a ſtar moving in the equator eaſtward, and never quickening or ſlackening its pace, but going through the equator in preciſely the ſame time as the ſun finiſhes his period in the ecliptic.

The motion of ſuch a ſtar will repreſent equal time, and its diurnal motion of the equator will be 59′ 8″, the ſame as the mean or equated motion of the ſun in the ecliptic; conſequently, the mean or equable day is determined by the arrival of the ſtar at the meridian, and is equal to the time wherein the whole circumference of the equator or 360° paſs the meridian, and 59′ 8″ more: which addition of 59′ 8″ remaining always the ſame, theſe mean or equated days will be conſtantly equal.

Since then the ſun goes unequally eaſtwards with reſpect to the equator, it will ſometimes arrive at the meridian ſooner than this imaginary ſtar, and ſometimes later: the difference is the difference between true and apparent time; which difference is known by having the place of the imaginary ſtar in the equator, and the point of the equator which comes to the meridian with the ſun; for the arch intercepted between them being converted into time, ſhews the difference between equal and apparent time, which, as before, is called the *equation of time*.

The *equation of time*, then, may be defined: the time that flows while the arch of the equator intercepted between the point determining the right aſcenſion of the ſun, and the place of the imaginary ſtar, paſſes the meridian; or as Tycho, and after him Street, ſtate it, it is the difference between the ſun's true longitude and his right aſcenſion.

To EQUATE *ſolar days, that is, to convert apparent into mean time, and mean into apparent time.* 1. If the ſun's right aſcenſion be equal to his mean motion, the imaginary and true ſun will paſs the meridian at the ſame time; conſequently, the true coincides with the apparent time.

2. If the right aſcenſion be greater than the mean motion, ſubtract the latter from the former; and turning the difference into ſolar time, either ſubtract it from the apparent time to find the mean time; or add it to the mean time to find the apparent.

3. Laſtly, if the right aſcenſion be leſs than the mean motion, ſubtract the former from the latter; and, turning the difference into ſolar time, either add it to the apparent time to find the mean time, or ſubtract it from the mean time to find the apparent.

This method of *equation* obtains, if the calculus be progreſſive; if it be retrograde, that is, if the time be reckoned backwards, the operation muſt be juſt the reverſe.

Or, find the mean and true anomalies for any propoſed day; their difference will be the EQUATION *of the centre*. The true anomaly gives the ſun's longitude, with which, and the obliquity of the ecliptic, compute the right aſcenſion; then add or ſubtract the difference between the longitude and right aſcenſion to or from the mean of the centre, and the ſum or difference, converted into time, gives the *equation* ſought.

This doctrine of the inequality and *equation* of natural days, is not only of uſe in aſtronomical obſervations, but alſo in the adjuſting and direction of clocks, watches, and other time-keepers: hence we ſee why a pendulum or other movement, which meaſures apparent equal time, does not keep pace with the ſun, which meaſures apparent time, but is ſometimes before, and ſometimes later than the ſame. Whence ſuch automata and ſun-dials are neceſſarily found almoſt perpetually at variance.

The variations of the two kinds of time are exhibited in the following tables for every day throughout the year. Mr. Flamſteed was the firſt who fully demonſtrated and cleared this inequality of natural days; though others, and even Ptolemy, had a partial notion of it.

The uſe of the tables is obvious; a clock or watch that is to be kept to true or equal time, muſt be ſo many minutes and ſeconds faſter or ſlower than a ſun-dial, as is aſſigned in the tables for the reſpective day; or if you would have it go by the ſun-dial, it goes well if it gains or loſes each day the number of minutes and ſeconds in the tables. See CLOCK.

TABLES of the EQUATION of natural Days, for regulating Clocks and Watches by the Sun.

N. B. No tables of this kind can be perpetual, because the preceſſion of the equinox, and the variation of the ſun's apogee produce a change in the inequality of his motion at the end of every year; but this change is ſo ſmall, that the ſame tables will ſerve without any ſenſible error for many years.

See tables of *equation of time* computed for every year, in the Nautical Almanac, by a method propoſed and illuſtrated by Mr. Maſkelyne, the aſtronomer royal, viz. by taking the difference of the ſun's true right aſcenſion and his mean longitude, corrected by the *equation* of the equinoxes in right aſcenſion, and turning it into time at the rate of 1′ of time to 15′ of right aſcenſion. Phil. Tranſ. vol. liv. art. 36. p. 336.

EQUATION, *abſolute*. See ABSOLUTE.

EQUATION *of the center*, called alſo *proſthaphareſis*, and *total proſthaphareſis*, is the difference between the true and mean place of a planet, or the angle made by the lines of the true and mean places; or, which amounts to the ſame, between the mean and equated ANOMALY.

The greateſt *equation of the center* may be obtained by finding the ſun's longitude at the times when he is near his mean diſtances, the difference will give the true motion for that interval of time: then find the ſun's mean motion for that interval of time, and half the difference between the true and mean motions will ſhew the greateſt *equation of the center*. E. G.

By obſervations made at the Obſervatory at Greenwich, it appears that

	d.	h.	′	″				
1769. Oct. 1, at	23	49	12		mean time, ſun's long. was	♎	6°	3′ 0″
1770. March 29, at	0	4	50		mean time, ſun's long. was	♈	8°	50′ 22″
The difference of time	178	0	15	38	True difference of long.		3°	29′ 22″

	d.	h.	′	″
The tropical year	= 365	5	48	42 = 365.2421527.
The obſerved interval	= 178	0	15	38 = 178.0108648.

Then 365.2421527 : 178.0108648 :: 360° : 175° 45′ 9″ mean motion. Therefore, 175° 27′ 21″ of mean motion anſwers to 179° 18′ 27″ true motion. Their difference = 3° 51′ 6″, and half this difference, viz. 1° 55′ 33″ is the greateſt *equation of the center* according to theſe obſervations.

To find the *equation of the center*, or to ſolve (what is called) *Kepler's* PROBLEM, is a very difficult operation, particularly in orbits, whoſe excentricity bears a conſiderable proportion to the mean difference: how this is to be done has been ſhewn by Newton, Gregory, Keil, Machin, La Caille, and others, by methods little differing from one another, which conſiſt chiefly in finding an intermediate angle, called the *excentric anomaly*; the mean anomaly and the dimenſions of the ſun's orbit being known. The mean anomaly is eaſily found, by determining the exact time of the ſun's paſſage through the aphelion, and uſing the following proportion, viz. as the time of a tropical revolution or ſolar year is to the interval between the aphelion and given time, ſo is 360° to the degrees of the mean anomaly; or, it may be found by taking the ſun's mean motion at the given time out of tables.

To find the excentric anomaly, let ADE (*Fab. II. Aſtronomy, fig.* 73.) be the excentric, AEP the earth's orbit, C the center, S the ſun, A the aphelion, P the perihelion, E the true place, D the correſponding place in the excentric, and B the mean place. In orbits of ſmall excentricities the true and mean places E and B approach one another, and the lines CD and SB approach to paralleliſm or coincidence; and therefore they may be conſidered as parallel, eſpecially in the earth's orbit, where CS is only about $\frac{1}{59}$ of CP: conſequently, ASB = ACD the excentric anomaly.

Then, in the triangle BCS, BC + CS = SA, and BC − CS = SP, and the angle BCS = ſupplement of ACB, are known, and therefore the angle CSB may be found; for, by a well-known trigonometrical theorem, CS + BC (= SA) : BC − CS (= SP) :: tang. $\frac{CSB+B}{2}$, or $\frac{1}{2}$ ACB : tang. of $\frac{CSD-B}{2}$, or of an arc, which added to $\frac{1}{2}$ ACB, will give CSB, the excentric anomaly; therefore, it may be found by the following proportion, as the aphelion diſtance is to the perihelion diſtance, ſo is the tangent of half the mean anomaly to the tangent of an arc, which, added to half the mean anomaly, will give the excentric anomaly. Then,

To find the true anomaly from the given excentric anomaly, and the dimenſions of the orbit, let a ſemicircle be deſcribed from E through the other focus *s*, interſecting AP in *n*, I, and SE, produced in G and H. Then, by Euclid, lib. iii. prop. 36. SH : SI :: SG $= \left(\frac{SI \times SI}{SH} = \frac{SI \times SI}{SE + EI}, =\right) \frac{2CF \times 2CS}{2CA}$, the chord I I being biſected by the perpendicular from the center DF. Therefore, CF × CS = (½ G =) ½ SE = ½ E I; CA (= ½ SE + ½ E*s*) being radius; or conſequently, ½ E = (1 + CS × CF, ſince the half difference of two quantities added to their half ſum gives the greater of them, =) 1 + CS × coſine, or Σ, ACD. Again, in the triangle SFE, SE : R :: SF : Σ, ASE = $\left(\frac{SF}{SE} =\right)$ $\frac{SC + \Sigma, ACD}{1 + SC \times \Sigma, ACD}$. Then 1 + Σ, ASE : 1 − Σ, ASE $= 1 + \frac{SC + \Sigma, ACD}{1 + SC \times \Sigma, ACD} : 1 - \frac{SC + \Sigma, ACD}{1 + SC \times \Sigma, ACD}$; or, $1 - \Sigma, ASE = \frac{1 + SC \times \Sigma, ACD - SC - \Sigma, ACD}{1 + \Sigma, ASE} = \frac{1 + SC \times \Sigma, ACD + SC + \Sigma, ACD}{1 - SC + SC \times \Sigma, ACD - \Sigma, ACD} =$ $\frac{1 + SC + SC \times \Sigma, ACD + \Sigma, ACD}{SP + CS - 1 \times \Sigma, ACD} = \frac{SP - \Sigma, ACD \times SP}{SA + CS + 1 \times \Sigma, ACD} = \frac{SA + \Sigma, ACD \times SA}{1 - \Sigma, ACD \times SP}$. But it is demonſtrated by trigono-

metrical

metrical writers, that radius leſs the coſine of an arc divided by radius more the coſine of an arc is equal to the ſquare of the tangent of half that arc divided by the ſquare of the radius; therefore,

$\frac{1-\Sigma.\ ASE}{1+\Sigma.\ ASE} = T^{a}.\ \frac{1}{2}ASE$; and $\frac{1-\Sigma.\ ACD}{1+\Sigma.\ ACD} \times \frac{SP}{SA}$

$T^{a}.\ \frac{1}{2}ACD \times \frac{SP}{SA}$

Then, $\frac{SP}{SA} \times T^{a}.\ \frac{1}{2}ACD = T^{a}.\ \frac{1}{2}ASE$, or $\frac{SP}{SA} = \frac{T^{a}.\ \frac{1}{2}ASE}{T^{a}.\ \frac{1}{2}ACD}$

Therefore, $\frac{\sqrt{SP}}{\sqrt{SA}} = \frac{T.\ \frac{1}{2}ASE}{T.\ \frac{1}{2}ACD}$; and $\sqrt{SA} : \sqrt{SP} :: T.\ \frac{1}{2}ACD : T.\ \frac{1}{2}ASE$.

Whence we have the following theorem; as the ſquare root of the aphelion diſtance is to the ſquare root of the perihelion diſtance, ſo is the tangent of half the excentric anomaly to the tangent of half the true anomaly.

The difference between the true and mean anomaly, or the angle CQS=ACB−ASE, is the *equation of the centre*, which muſt be ſubtracted, from the aphelion to the perihelion, or in the firſt ſix ſigns of anomaly, and added, from the perihelion to the aphelion, or in the ſix laſt ſigns of anomaly, and hence called PROSTHAPHÆRESIS.

For the lines CB, SE, CA, SE, which coincide in SA, SP, will in every other poſition croſs one another, in Q, while revolving from A to P, and in γ, while revolving from P to A: in the firſt half revolution, the mean anomaly, or the external angle ACB exceeds the angle ASE, the true anomaly, by the angle CQS; in the latter half, the true anomaly, or external angle PSA, exceeds the mean anomaly or the angle PCB by the angle $S\gamma C$.

By this problem a table may be eaſily formed; when the *equations of the centre* for every degree of the firſt ſix ſigns of mean anomaly are found, theſe will alſo ſerve for the degrees of the laſt ſix ſigns, becauſe equal anomalies are at equal diſtances on both ſides of their apſides: then ſet theſe *equations* orderly to their ſigns and degrees of anomaly; the firſt ſix being reckoned from the top of the table downwards, and ſigned *ſubtract*; the laſt ſix, for which the ſame *equations* ſerve, in a contrary order, being reckoned from the bottom upwards, and marked *add*, and ſet the difference between every adjacent two *equations*, called *tabular differences*, be ſet in another column: from theſe *equations of the centre*, augmented or diminiſhed by the proportional parts of their reſpective tabular differences for any given minutes and ſeconds, may be eaſily deduced *equations of the centre* to any given mean anomaly.

TABLE of the EQUATION of the *Sun's Centre* to each Sign and Degree of Mean Anomaly.

Robertſon's Elem. of Navig. book v. p. 286—290. 295—308.

Mr. Euler has particularly conſidered this ſubject in Mem. de l'Acad. de Berlin, tom. ii. p. 225. ſeq. where he ſolves the following problems:

1. To find the true and mean anomaly correſponding to the planet's mean diſtance from the ſun; that is, when the planet is in the extremity of the conjugate axis of its orbit.

2. The excentricity of a planet being given, to find the excentric anomaly correſponding to the greateſt *equation*.

3. The excentricity being given, to find the mean anomaly correſponding to the greateſt *equation*.

4. From the ſame data to find the true anomaly correſponding to this *equation*.

5. From the ſame data to find the greateſt *equation*.

6. The greateſt equation being given to find the excentricity. Mr. Euler obſerves, that this problem is very difficult, and that it can only be ſolved by approximation and tentatively in the manner he mentions; but, if the excentricity be not great, it may be then found directly from the greateſt *equation*. Thus, if the greateſt *equation*$=m$, and the excentricity$=n$, then,

$$m = 2n + \frac{11}{48}n^{3} + \frac{599}{5120}n^{5} +, \text{ &c.}$$

Whence by converſion,

$$n = \frac{1}{2}m - \frac{11}{768}m^{3} - \frac{587}{2^{16}.15}m^{5} -, \text{ &c.}$$

Where the greateſt *equation*, m, muſt be expreſſed in parts of the radius, which may be done by converting the angle m into ſeconds, and adding 4,6855749 to the logarithm of the reſulting number; for this will be the logarithm of the number m.

The mean anomaly to which this greateſt *equation* correſponds will be $x = 90° + \frac{5}{8}m - \frac{5}{2^{6}.3}m^{3} - \frac{1}{2^{6}.5}m^{5} -$, &c.

Whence, if to 90° we add $\frac{5}{8}$ of the greateſt *equation*, we ſhall ſufficiently approximate to this mean anomaly.

Mr. Euler gives us a table, in which may be found the greateſt *equations*, the excentric and mean anomalies correſponding to theſe greateſt *equations* for every hundredth part of unity, which he ſuppoſes equal to the greateſt excentricity, or when the diſtance of the foci and the tranſverſe axis become infinite. The laſt column of his table alſo gives us the logarithm of that diſtance of the planet from the ſun where its *equation* is greateſt. By the help of this table, any excentricity being given, we may find the greateſt correſponding *equation* by interpolation. But the principal uſe of the table is to determine the

the eccentricity when the greatest *equation* is known; and Mr Euler thinks the question infoluble without this help. See the Table, lib. cit. p. 225, seq.

The motions of the fun and moon are affected with various inequalities, whence arifes the neceſſity of ſo many *equations*.

From theſe inequalities, the moon's place become exceeding difficult to be determined; to remove which difficulty, is the great deſign of ſir Iſaac Newton's New Theory of the Moon, wherein we are furniſhed with *equations* for all the inequalities of the mean motion.

The principal of theſe are,

EQUATIONS, *annual, of the mean motion of the ſun and moon, and of the apogee and node of the moon.*

The annual *equation* of the ſun's centre being given, the three other correſponding annual *equations* will be alſo given, and therefore a table of that will ſerve for all. For if the annual *equation* of the ſun's centre be taken from thence for any time, and be called P, and let $\frac{1}{2}$ P = Q, $\frac{1}{4}$ P = R, $\frac{1}{8}$ P = S, $\frac{1}{16}$ P = T, and D = $\frac{1}{2}$ T = $\frac{1}{32}$ P; then ſhall the annual *equation* of the moon's mean motion for that time be R, that of the apogee of the moon will be E, and that of the node F.

Only obſerve, that if the *equation* of the ſun's centre be required to be added, then the *equation* of the moon's mean motion muſt be ſubtracted, that of her apogee muſt be added, and that of the node ſubducted; and, on the contrary, if the *equation* of the ſun's centre were to be ſubducted, the moon's *equation* muſt be added, the *equation* of her apogee ſubducted, and that of her node added.

There is alſo an *equation of the moon's mean motion*, depending on the ſituation of her apogee in reſpect of the ſun, which is greateſt when the moon's apogee is in an octant with the ſun, and is nothing at all when it is in the quadratures or ſyzygies. This *equation*, when greateſt, and the ſun in perigee, is 3 min. 56 ſeconds. But if the ſun be in apogee, it will never be above 3 min. 34 ſeconds. At other diſtances of the ſun from the earth, this *equation*, when greateſt, is reciprocally as the cube of that diſtance. But when the moon's apogee is any where but in the octants, this equation grows leſs; and is moſtly at the ſame diſtance between the earth and ſun, as the ſine of the double diſtance of the moon's apogee from the next quadrature or ſyzygy to the radius. This is to be added to the moon's motion while her apogee paſſes from a quadrature with the ſun to a ſyzygy; but is to be ſubtracted from it, while the apogee moves from the ſyzygy to the quadrature.

There is, moreover, another *equation of the moon's motion*, which depends on the aſpect of the nodes of the moon's orbit with reſpect to the ſun; and this is greateſt when her nodes are in octants to the ſun, and vaniſhes quite when they come to their quadratures or ſyzygies. This *equation* is proportional to the ſine of the double diſtance of the node from the next ſyzygy or quadrature; and at the greateſt, is but 47 ſeconds. This muſt be added to the moon's mean motion while the nodes are paſſing from the ſyzygies with the ſun to their quadratures with him, but ſubtracted while they paſs from the quadratures to the ſyzygies.

From the ſun's true place take the equated mean motion of the lunar apogee as was above ſhewed, the remainder will be the annual argument of the ſaid apogee; from whence the excentricity of the moon and the ſecond *equation* of her apogee may be compared. See *Theory of the* MOON'S *Motion*, &c.

EQUATION, *excentric*. See EXCENTRIC.

EQUATION, *lunar and ſolar*, in *Chronology*. See METEMPTOSIS.

EQUATOR, or ÆQUATOR, in *Aſtronomy* and *Geography*, a great circle of the ſphere, equally diſtant from the two poles of the world, or having the ſame poles with thoſe of the world.

Such is the circle DA (*Tab. Aſtron. fig.* 52) its poles being P and Q. It is called the *equator*, becauſe when the ſun is in it the days and nights are *equal*; whence alſo it is called the *equinoctial*; and when drawn on maps and planiſpheres, the *equinoctial line*, or ſimply, the *line*. Every point of the *equator* is a quadrant's diſtance from the poles of the world; whence it follows, that the *equator* divides the ſphere into two hemiſpheres, in one of which is the northern, and in the other the ſouthern pole.

By the paſſages or tranſits of arcs of the *equator* over the meridian, equal or mean time is eſtimated: hence we have frequent occaſion for the converſion of degrees of the *equator* into time; and again, for the re-converſion of parts of time into degrees or parts of the *equator*.

For performance whereof, we ſubjoin the following table; wherein are exhibited the arcs of the *equator*, which paſs the meridian in the ſeveral hours, minutes, &c. of equated or mean time.

Converſion of the parts of the *equator* into Time, and *vice verſa*.

Deg. of *Equat.*	Hours.	Min.	Hours.	Deg. of *Equat.*	Hour. Min.	Deg. of *Equat.*	′
Min.	Min.	Sec.	Min.	Min.	Sec.	Min.	″
Sec.	Sec.	Third	Sec	″ Sec	‴ Third	Sec.	′ ″ ‴
Third.	Third.	Fourth.	Th.	‴ Th.	⁗ Fourth	Th.	″ ‴ ⁗
1	0	4	1	15	1	0	15
2	0	8	2	30	2	0	30
3	0	12	3	45	3	0	45
4	0	16	4	60	4	1	0
5	0	20	5	75	5	1	15
10	0	40	6	90	6	1	30
15	1	0	9	135	10		
30	2	0	12	180	20		
60	4	0	15	225	30		
90	6	0	18	270	40	10	
180	12	0	21	315	50	12	
360	24	0	24	360	60	15	

The conſtruction of this table is very eaſy: for the *equator* being divided into 360 degrees, and revolving always in 24 hours, any point of it moves through 15° in one hour, and in one minute through the 60th part of 15°, or 15′ of a degree, and in one ſecond through 15″ of a degree, &c. and therefore nothing more is neceſſary beſides ſimple addition, in order to have the number of degrees, minutes, and ſeconds, which it deſcribes in any given time.

The uſe of the table is obvious: ſuppoſe, e. gr. it were required to turn 19° 15′ 7″ of the *equator* into time: againſt 15 deg. in the firſt column we have 1h 0′ 0″; againſt 4 deg. we have 16′ 0″; againſt 10 minutes, 40″; againſt 5 minutes, 20″ 0‴; againſt 5 ſeconds, we have 0′ 20″ 0‴; and againſt 2 ſeconds, 8‴; which, added together give 1h 16′ 52″ 28‴.

Again, ſuppoſe it were required to find how many degrees, minutes, &c. of the *equator* anſwer to 23 hours 25 min. 17 ſec. and 9 thirds. Againſt 21h in the fourth column of the table, you have 315°; and againſt 2 hours, 30′; againſt 20′, 5′; againſt 5′, 1° 15′; againſt 10 ſec. 2′ 30″; againſt 5 ſec. 1′ 15″ 0‴; againſt 2 ſec. 30″ 0‴; againſt 6 thirds, 1″ 30‴; and againſt 3 thirds, 45‴; which, added together, give 351° 19′ 17″ 15‴. See EQUINOCTIAL.

EQUATOR, *elevation or altitude of the*. See ELEVATION *of the equator*.

EQUATOREAL, *univerſal*, in *Aſtronomy*, is the name of an excellent inſtrument lately conſtructed by Mr. Ramſden, an ingenious philoſophical inſtrument maker in London. The principal parts of this *equatoreal* (ſee *Tab.* II. *Aſtronomy, fig.* 74.) are 1. The azimuth or horizontal circle A, which repreſents the horizon of the place and moves on a long axis B, called the vertical axis. 2. The *equatoreal* or hour circle C, repreſenting the equator, placed at right angles to the polar axis D, or the axis of the earth, upon which it moves. 3. The ſemicircle of declination E, on which the teleſcope is placed, and moving on the axis of declination, or the axis of motion of the line of collimation F. Theſe circles are meaſured and divided as in the following table:

Meaſures of the ſeveral circles and diviſions on them.	Number in a circle.	Limb divided to	Means to give ſeconds.	Divided on limb ſo as to give	Or into by Months into hours of limb.
Azimuth or horizontal circle	1	15′	30″	45th	1350th
Equatoreal or hour circle	1	15′ / 1 minute	30″ / 2″	45th	1350th
Vertical ſemicircle for declination or latitude	5	15′	30″	42d	1260th

4. The teleſcope, which is an achromatic refractor with a triple object glaſs, whoſe focal diſtance is 17 inches, and aperture 2,45 inches, and furniſhed with 6 different eye-tubes; ſo that its magnifying powers extend from 44 to 168. The teleſcope in this *equatoreal* may be brought parallel to the polar axis, as in the figure, ſo as to point to the pole ſtar in any part of its diurnal revolution; and thus it has been obſerved near noon, when the ſun has ſhone very bright. 5. The apparatus for correcting the error in altitude occaſioned by refraction, which is applied to the eye-end of the teleſcope, conſiſts of a ſlide G moving in a groove or dove-tail, and carrying the ſeveral eye-tubes of the teleſcope, on which ſlide there is an index correſponding to 5 ſmall diviſions engraved on the dove-tail; a very ſmall circle, called the refraction circle H, moveable by a finger-ſcrew at the extremity of the eye end of the teleſcope; which circle is divided into half minutes, one entire revolution of it being equal to 3′ 18″, and by its motion raiſes

the

the centre of the cross-hairs on a circle of altitude; and likewise a quadrant 1 of 1½ inch radius, with divisions on each side, one expressing the degree of altitude of the object viewed, and the other expressing the minutes and seconds of error, occasioned by refraction, corresponding to that degree of altitude: to this quadrant is joined a small round level K, which is adjusted partly by the pinion that turns the whole of this apparatus, and partly by the index of the quadrant; for which purpose the refraction circle is set to the same minute, &c. which the index points to on the limb of the quadrant; and if the minute, &c. given by the quadrant exceed the 3′ 18″ contained in one entire revolution of the refraction circle, this must be set to the excess above one or more of its entire revolutions; then the centre of the cross-hairs will appear to be raised on a circle of altitude to the additional height which the error of refraction will occasion at that altitude.

This instrument stands on three feet L distant from each other 14,4 inches; and when all the parts are horizontal is about 29 inches high: the weight of the *equatoreal* and apparatus is only 59 lb. avoirdupoise, which are contained in a mahogany case weighing 56 lb.

The principal adjustment in this *instrument* is that of making the line of collimation to describe a portion of an hour-circle in the heavens; in order to which, the azimuth circle must be truly level, the line of collimation or some corresponding line represented by the small brass rod M parallel to it, must be perpendicular to the axis of its own proper motion; and this last axis must be perpendicular to the polar axis: on the brass rod M there is occasionally placed a hanging level N, the use of which will appear in the following adjustments.

The azimuth circle may be made level by turning the instrument till one of the levels is parallel to an imaginary line joining two of the feet screws; then adjust that level with these two feet screws; turn the circle half round, i. e. 180°; and if the bubble be not then right, correct half the error by the screw belonging to the level, and the other half error by the two foot screws; repeat this till the bubble comes right; then turn the circle 90° from the two former positions, and set the bubble right, if it be wrong, by the foot screw at the end of the level; when this is done, adjust the other level by its own screw, and the azimuth circle will be truly level. The hanging level must then be fixed to the brass rod by two hooks of equal length, and made truly parallel to it: for this purpose make the polar axis perpendicular or nearly perpendicular to the horizon; then adjust the level by the pinion of the declination semicircle; reverse the level, and if it be wrong, correct half the error by a small steel screw that lies under one end of the level, and the other half error by the pinion of the declination semicircle; repeat this till the bubble be right in both positions. In order to make the brass rod on which the level is suspended at right angles to the axis of motion of the telescope or line of collimation, make the polar axis horizontal, or nearly so; set the declination semicircle to 0°, turn the hour-circle till the bubble comes right; then turn the declination circle to 90°; adjust the bubble by raising or depressing the polar axis, (first by hand till it be nearly right, afterwards tighten with an ivory key the socket which runs on the arch with the polar axis, and then apply the same ivory key to the adjusting screw at the end of the said arch till the bubble comes quite right); then turn the declination-circle to the opposite 90°; if the level be not then right, correct half the error by the aforesaid adjusting screw at the end of the arch, and the other half error by the two screws which raise or depress the end of the brass rod. The polar axis remaining nearly horizontal as before, and the declination semicircle at 0°, adjust the bubble by the hour-circle; then turn the declination-semicircle to 90°, and adjust the bubble by raising or depressing the polar axis; then turn the hour-circle 12 hours; and if the bubble be wrong correct half the error by the polar axis, and the other half error by the two pair of capstan screws at the feet of the two supports on one side of the axis of motion of the telescope; and thus this axis will be at right angles to the polar axis. The next adjustment is to make the centre of cross-hairs remain on the same object, while you turn the eye tube quite round by the pinion of the refraction apparatus: for this adjustment, set the index on the slide to the first division on the dove-tail; and set the division marked 18″ on the refraction-circle to its index; then look through the telescope, and with the pinion turn the eye-tube quite round; and if the centre of the hairs does not remain on the same spot during that revolution, it must be corrected by the four small screws, two and two at a time, which you will find upon unscrewing the nearest end of the eye-tube that contains the first eye-glass; repeat this correction till the centre of the hairs remains on the spot you are looking at during an entire revolution.

In order to make the line of collimation parallel to the brass rod on which the level hangs, set the polar axis horizontal, and the declination circle to 90°; adjust the level by the polar axis; look through the telescope on some distant horizontal object, covered by the centre of the cross-hairs; then invert the telescope, which is done by turning the hour circle half round; and if the centre of the cross hairs does not cover the same object as before, correct half the error by the uppermost and lowermost of the four small screws at the eye-end of the large tube of the telescope; this correction will give a second object now covered by the centre of the hairs, which must be adopted instead of the first object; then invert the telescope as before; and if the second object be not covered by the centre of the hairs, correct half the error by the same two screws which were used before: this correction will give a third object, now covered by the centre of the hairs, which must be adopted instead of the second object; repeat this operation till no error remains; then set the hour-circle exactly to 12 hours, (the declination-circle remaining at 90° as before); and if the centre of the cross hairs does not cover the last object fixed on, set it to that object by the two *remaining* small screws at the eye-end of the large tube, and then the line of collimation will be parallel to the brass rod. For rectifying the Nonius of the declination and *equatoreal* circles, lower the telescope as many degrees, minutes, and seconds, below 0° or A. on the declination-semicircle as are equal to the complement of the latitude; then elevate the polar axis till the bubble be horizontal, and thus the *equatoreal* circle will be elevated to the co-latitude of the place; set this circle to 6 hours; adjust the level by the pinion of the declination-circle; then turn the *equatoreal* circle exactly 12 hours from the last position; and if the level be not right, correct one half of the error by the *equatoreal* circle, and the other half by the declination-circle; then turn the *equatoreal* circle back again exactly 12 hours from the last position; and if the level be still wrong, repeat the correction as before till it be right, when turned to either position; that being done, set the Nonius of the *equatoreal* circle exactly to 6 hours, and the Nonius of the declination-circle exactly to 0°.

The principal uses of this *equatoreal* are,

1. To find your meridian by one observation only: for this purpose, elevate the *equatoreal* circle to the co-latitude of the place, and set the declination-semicircle to the sun's declination for the day and hour of the day required; then move the azimuth and hour-circles both at the same time, either in the same or contrary direction, till you bring the centre of the cross hairs in the telescope exactly to cover the centre of the sun; when that is done, the index of the hour circle will give the apparent or solar time at the instant of observation; and thus the time is gained, though the sun be at a distance from the meridian; then turn the hour-circle till the index points precisely at 12 o'clock, and lower the telescope to the horizon, in order to observe some point there in the centre of your glass, and that point is your meridian mark found by one observation only; the best time for this operation is three hours before or three hours after 12 at noon.

2. To point the telescope on a star, though not on the meridian, in full day-light. Having elevated the *equatoreal* circle to the co-latitude of the place, and set the declination-semicircle to the star's declination, move the index of the hour-circle till it *shall* point to the precise time at which the star is then distant from the meridian, found in tables of the right ascension of the stars, and the star will then appear in the *glass*. Beside these uses peculiar to this instrument, it is also applicable to all the purposes to which the principal astronomical instruments, viz. a transit, a quadrant, and an equal altitude instrument, are applied. See the description and drawing of an *equatoreal* telescope, or portable observatory, invented by Mr. Short, in the Phil. Trans. N° 493. or vol. xlvi. p. 242, &c. And another by Mr. Nairne, vol. lxi. part i. art. 14. p. 107. See a method of correcting refraction in the use of the *equatoreal* by Mr. Dollond in Phil. Trans. vol. lxix. part ii. p. 332, &c.

EQUERY, or ECURY, a grand stable or lodge for horses, furnished with all the conveniencies thereof; as stall's, manger, rack, &c.

The word is formed from the French, *escurie*, which signifies the same thing: Some again derive *escurie* from the Latin, *furia*, which not only denotes a place for beasts to be put up in, but also a grange or barn. But a more probable derivation is from *equile*, *a stable for horses, of equus, horse*.

Some hold that the word *stable*, in propriety, relates only to bullocks, cows, sheep, hogs, &c. and *equery*, to horses, mules, &c.

A *simple equery* is that provided for one row of horses; a *double equery* that provided for two, with a pat-

sage in the middle, or two paſſages; the horſes being placed head to head, as in the little *equery* at Verſailles.

Under *equery* are ſometimes alſo comprehended the lodgings and apartments of the *equeries*, grooms, pages, &c.

EQUERY, *ecuyer*, is alſo an officer who has the care and management of the horſes of a king or prince.

EQUERRIES, or EQUERRIES, popularly called QUERRIES, are particularly uſed among us for officers of the king's ſtables, under the maſter of the horſe, ſeven in number, who, when his majeſty goes abroad, ride in the leading-coach, are in waiting one at a time monthly, and have a table with the gentlemen-uſhers during the time, and a ſalary of 300*l.* a year each.

They uſed to ride on horſeback by the coach-ſide when the king travelled; but that being more expenſive to them than neceſſary to the ſovereign, it has been diſcontinued.

EQUERIES *of the crown ſtable* have that appellation, as being employed in managing and breaking the ſaddle-horſes, and preparing them for the king's riding.

Theſe are two in number; the firſt having an annual ſalary of 256*l.* and the ſecond 200*l.* whereof one is, or always ſhould be, in cloſe waiting at court; and when his majeſty rides, holds the ſtirrup, while the maſter of the horſe, or one of the *equeries* in his abſence, aſſiſts in mounting him; and when his majeſty rides, they uſually attend him.

EQUES *auratus*, is uſed to ſignify a knight bachelor, called *auratus*, q. d. *gilt*, becauſe anciently none but knights might gild or beautify their armour, or other habiliments of war, with gold.

In law, this term is not uſed, but inſtead of it *miles*, and ſometimes *chevalier*.

EQUESTRIA, among the Romans, a place in the theatre where the equites or knights ſat.

EQUESTRIS, EQUESTRIAN, a term chiefly uſed in the phraſe *equeſtrian ſtatue*, which ſignifies a ſtatue repreſenting a perſon mounted on horſeback.

The word is formed of the Latin, *equus*, *knight*, *horſeman*, of *equus*, *horſe*.

The *Fortuna equeſtris*, in ancient Rome, was a ſtatue of the goddeſs on horſeback. We ſometimes alſo ſay, *Equeſtrian* COLUMN.

EQUESTRIAN *cohort*, in *Antiquity*. See COHORS *equitata*.

EQUESTRIAN *games*, *ludi equeſtres*, among the Romans, horſe-races, of which there were five kinds, the *prodromus*, or *plain horſe-race*, the *chariot race*, the *decurſory race*, about funeral piles, the *ludi ſcenicales*, and the *ludi natatiles*.

EQUESTRIAN *order*, among the Romans, ſignified the order of knights or *equites*.

EQUIANGULAR, or ÆQUIANGULAR, in *Geometry*, is applied to figures whoſe angles are all equal. See ANGLE.

A ſquare is an *equiangular* figure. See SQUARE. All equilateral triangles are alſo *equiangular*.

EQUICRURAL, or ÆQUICRURAL *triangle*, is what we more uſually call an ISOSCELES *triangle*.

EQUICULUS, EQUULEUS, or EQUUS *minor*, a conſtellation of the northern hemiſphere. See EQUULEUS.

EQUIDIFFERENT, or ÆQUIDIFFERENT, in *Arithmetic*. If in a ſeries of three quantities there be the ſame difference between the firſt and ſecond as between the ſecond and third, they are ſaid to be *continually equidifferent*; but, if in a ſeries of four quantities there be the ſame difference between the firſt and ſecond as between the third and fourth, they are ſaid to be *diſcretely equidifferent*.

Thus, 3. 6, 7, and 10, are diſcretely *equidifferent*, and 3, 6, and 9, continually *equidifferent*.

EQUIDISTANT, or ÆQUIDISTANT, in *Geometry*, a term of relation between two things which are every where at an equal or the ſame diſtance from each other. See DISTANCE.

Thus, parallel lines are ſaid to be *equidiſtant*, as they neither approach nor recede.

EQUILATERAL, or ÆQUILATERAL, of *æquus*, *equal*, and *latus*, *ſide*, is applied to any thing whoſe ſides are all equal.

Thus, an *equilateral* triangle is that whoſe ſides are all of equal length. In an *equilateral* triangle all the angles are likewiſe equal.

All regular polygons and regular bodies are *equilateral*. See POLYGON, REGULAR, &c.

EQUILATERAL *hyperbola*, is that wherein the conjugate axes, as A B and D E are equal. *Tab. Con. fig.* 20.

Hence, as the parameter is a third proportional to the conjugate axes, it is alſo equal thereto; conſequently, if in the equation $y^2 = b \times \frac{+bx^2}{a}$, we make $b = a$: the equation $y^2 = x + x^2$, defines the nature of an *equilateral hyperbola*. See HYPERBOLA.

EQUILIBRIUM, or ÆQUILIBRIUM, in *Mechanics*, a term implying an exact equality of momentum or force between two bodies compared with each other; and this takes place when their directions are equally oppoſite, and their maſſes are reciprocally proportional to the velocities with which they tend to move. See FORCE.

A balance is in *equilibrio* when the two ends are ſo exactly poiſed that neither of them aſcends or deſcends, but both retain their parallel poſition to the horizon. From this circumſtance the word is originally taken, as being a compound of *æquus*, *equal*, and *libra*, *balance*; whence we frequently uſe the word *balance* in lieu thereof.

The *equilibrium* of fluids make a conſiderable part of the doctrine of hydroſtatics. See FLUID.

EQUILIBRIUM, is alſo uſed figuratively on other occaſions. A painter muſt take care to obſerve the *equilibrium* of his figures, i. e. diſpoſe them well on their centre of gravity that they may not ſeem ill-ſupported, or ready to tumble. Thus, e. gr. if one arm be moved forward, the other muſt be proportionably backward to poiſe the figure.

In a picture there ſhould always be an *equilibrium* between one part and another; that is, the objects are to be diſtributed ſo as to balance and contraſt each other; and not too many, e. gr. be crouded on one ſide, and the other be left bare.

EQUIMULTIPLE, in *Arithmetic* and *Geometry*, is applied to ſimple magnitudes when multiplied equally, i. e. by equal quantities or multipliers.

Thus, taking A as many times as B, or multiplying them equally, there will ſtill remain the ſame ratio between the magnitudes thus multiplied as between the primitive magnitudes before multiplication.

Now, thoſe magnitudes thus equally multiplied are called *equimultiples* of the original ones A and B; whence we ſay, that *equimultiples* have the ſame ratio as the ſimple quantities. In arithmetic, we generally uſe the term *equimultiples* for numbers which contain equally or an equal number of times their *ſubmultiples*.

Thus 12 and 6 are *equimultiples* of their *ſubmultiples* 4 and 2, inaſmuch as each of them contains its *ſubmultiple* three times.

EQUINA *ſella*. See the article SELLA.

EQUINOCTIAL, or ÆQUINOCTIAL, in *Aſtronomy*, a great and immoveable circle of the ſphere, under which the equator moves in its diurnal motion.

The *equinoctial*, or *equinoctial line*, is ordinarily confounded with the equator; but there is a difference, the equator being moveable, and the *equinoctial* immoveable; and the equator being drawn about the convex ſurface of the ſphere, but the *equinoctial* on the concave ſurface of the magnus orbis.

The *equinoctial* is conceived by ſuppoſing a ſemidiameter of the ſphere produced through a point of the equator, and there, by the rotation of the ſphere about its axis, deſcribing a circle on the immoveable ſurface of the primum mobile.

Whenever the ſun, in his progreſs through the ecliptic, comes to this circle, it makes equal days and nights all around the globe; as then riſing due eaſt and ſetting due weſt, which he never does at any other time of the year. And hence the denomination from *æquus* and *nox*, *night*, *quia æquat diem nocti*.

The *equinoctial*, then, is the circle which the ſun deſcribes, or appears to deſcribe, at the time of the equinoxes; that is, when the length of the day is every-where equal to that of night, which happens twice a year. See EQUINOX.

EQUINOCTIAL, in *Geography*. See EQUATOR.

The ſhadows of thoſe who live under this circle are caſt to the ſouthward of them for one half of the year, and to the northward of them during the other half; and twice in a year, viz. at the equinoxes, the ſun at noon calls no ſhadow, being in their zenith.

From this circle is the declination or latitude of places accounted in the degrees of the meridian.

EQUINOCTIAL *points*, are the two points wherein the equator and ecliptic interſect each other: the one, being in the firſt point of Aries, is called the *vernal point*, or *equinox*; and the other in the firſt point of Libra, the *autumnal point*, or *equinox*.

EQUINOCTIAL *colure*, is that paſſing through the *equinoctial* points. See COLURE.

EQUINOCTIAL *dial*, is that whoſe plane lies parallel to the *equinoctial*. See DIAL.

EQUINOCTIAL *hours*, *line*, *wind*. See the ſubſtantives.

EQUINOX, or ÆQUINOX, in *Aſtronomy*, the time when the ſun enters one of the EQUINOCTIAL *points*.

The *equinoxes* happen when the ſun is in the *equinoctial* circle; when of conſequence the days are equal to the nights throughout the world, which is the caſe twice a year, viz. about the 20th of March and the 23d of September, the firſt of which is the *vernal*, and the ſecond the *autumnal equinox*.

As the sun's motion is unequal, that is, sometimes swifter and sometimes slower (from the causes already explained under the article EQUATION) it comes to pass, that there are about eight days more from the vernal to the autumnal *equinox* than from the autumnal to the vernal, the sun spending so much more time in travelling through the northern than the southern signs.

According to the observations of M. Cassini, the sun is 186d 14h 53′ in the northern signs, and only 178d 14h 56′ in the southern. The difference of which is 7d 23h 57′.

The sun, continually advancing forwards in the ecliptic and gaining a degree every day, makes no stay in the equinoctial points, but the moment he arrives in them he also leaves them.

Of course, therefore, though the day the sun enters the equinoctial point is called the *equinox*, as being reputed equal to the night; yet it is not precisely so, unless the sun enter the equator at mid-day: for if the sun rising should enter the vernal *equinox*, at setting he will have departed from it, and have got northwards about 12′; consequently, that day will be somewhat longer than 12 hours, and the night proportionably shorter.

The time of the *equinoxes*, i. e. the moment in which the sun enters the equator, is found by observation, the latitude of the place of the observation being given.

Thus, in the equinoctial day, or near it, take the just meridian altitude of the sun; if this be equal to the altitude of the equator, or the complement of the latitude, the sun is that very moment in the equator: if it be not equal, the difference is the sun's declination. The next day observe the meridian altitude as before, and find his declination; if the declination be of different kinds, viz. the one north and the other south, the *equinox* has happened in the interval of time between them; otherwise, the sun has not entered the equinoctial, or had passed it at first. From these observations a trigonometrical calculus gives the time of the *equinox*.

Thus, let DG (*Tab. II. Ast. fig.* 75.) represent the equator, AC the ecliptic, E the equinoctial point; the points A, B, C, the places of the sun at the times of observation; the arcs AD, BF, CG, the corresponding declinations; in the right angled spherical triangles CEG, BEF, the obliquity of the ecliptic, and the declinations are known; whence may easily be found EC, EB; then BC, the sum or difference of EC, EB, is the ecliptic arc described in 24 hours; then say as BC : BE :: 24 hours for B C : time for B E; and this time shews the distance of the *equinox* from the time of the middle observation.

It is found by observation, that the equinoctial points, and all the other points of the ecliptic, are continually moving backward, or in antecedentia, that is, westward. This retrograde motion of the equinoctial points is that famous and difficult phænomenon called the *precession of the equinoxes*. See PRECESSION *of the equinoxes*.

EQUINUS *barbatus*, a kind of comet. See HIPPEUS.

EQUINUS *elapticus* and *quadrangularis*. See HIPPEUS.

EQUINUS *ventus*. See VENTER *equi*.

EQUIPAGE, in the *Military Art*, denotes all sorts of utensils, artillery, &c. necessary for commencing and prosecuting with ease and success any military operations. Camp and field *equipage* consists of tents, kitchen furniture, saddle-horses, baggage, waggons, but-horses, &c.

EQUIPAGE, in *Navigation*. See CREW, and FITTING-OUT.

To EQUIP, in *Naval Language*, a term borrowed from the French marine, and frequently applied to the business of fitting a ship for sea, or arming her for war. See FITTING-OUT.

EQUIPOLLENCE, in *Logic*, is when there is an equivalence between any two or more terms or propositions; i. e. when they signify one and the same thing, though they express it differently. Such propositions, &c. are said to be *equipollent*.

EQUIPPE, in *Heraldry*, expresses a cavalier equipped, i. e. armed at all points.

EQUIRIA, in *Antiquity*, a festival instituted by Romulus, and celebrated on the 27th of February, in honour of Mars, at which there were horse-races.

EQUISELIS, in *Natural History*, the name of a large fly, of the size of a hornet, but having only two wings and no sting: it otherwise much resembles the common hornet in shape. This fly is found only in Macedonia. We have also in England flies which nearly resemble the hornet, wasp, and bee, but in their wanting stings and having only two wings.

EQUISELIS, in *Ichthyology*, a name used by some authors for the hippuris, a sea-fish, caught on the Spanish shores, and supposed by many to be the same with the DORADA, or CORYPHENA with the forked tail of Artedi. See HIPPURIS.

EQUISETUM, in *Botany*. See HORSE-*tail*.

EQUITATA *cohors*, in *Antiquity*. See COHORS *equitata*.

EQUITY, *Æquitas*, denotes justice or right, mitigated, and tempered by the consideration of particular circumstances; or a correction and abatement of the severity of some law; or a temperament, which, without being unjust, abates the rigour of some just law.

This is what the Greeks call ἐπιείκεια. The utmost severity of a good law is frequently contrary to justice; it should always have *equity* for its rule and guide. *Summum jus, sæpe summa injuria.*

The foundation of *equity* is not that there is any mistake in the law, but that the law was laid down universally, because all circumstances could not be considered or taken in under one law.

For an instance, suppose it an express law, that the city being now beset with an enemy, the gates be all shut; and suppose it fall out that the enemy is then in pursuit after some of the citizens by whom it is defended, so that it would be highly prejudicial thereto not to open for them the gates; *equity* here decrees the gates to be opened, contrary to the express word of the law.

Equity is of two kinds, and those of contrary effects; the one abridges, and takes from the letter of the law; and the other enlarges, and adds thereto.

The first is defined the correction of a law, made generally in that part wherein it fails; as suppose a statute made, "That whosoever does such a thing shall be a "felon or suffer death:" yet if a mad-man, or an infant, who hath no discretion, do the same, he shall neither be a felon nor suffer death.

The other is defined an extension of the words of the law to cases which are not expressed, which yet come under the same reason; so that when one thing is enacted, all other things which are of the like degree are so too.

Thus, the statute which ordains, that in action of debt against executors, he who appears by distress shall answer, extends by *equity* to administrators; and such of them as shall appear first by distress, shall answer by the *equity* of the said act, *quia sunt in æquali genere*.

EQUITY is also used for the virtue of JUSTICE.

EQUITY, in our *Laws*, &c. is also frequently used for the court of chancery, where controversies are supposed to be determined according to the exact rules of *equity* and conscience, by mitigating the rigour of the common law.

Æquitas sequitur legem, is an old maxim in law; but, from the great increase of suits in chancery, some have thought fit to give it this construction, that in all cases after a man has been at law, he must go to *equity*.

EQUITY *of redemption*, on mortgages, is that right which a mortgager has of redeeming his estate upon payment of the money borrowed. If where money is due on a mortgage, the mortgagee is desirous to have the *equity of redemption*, he may oblige the mortgagor either to pay the money, or be foreclosed of his *equity*; which is done by proceedings in the court of chancery. But the chancery cannot shorten the time of payment of the mortgage money, where it is limited by express covenant, though it may lengthen it, and then upon non-payment, the practice is to foreclose the *equity of redemption* of the mortgagor. 2 Vern. 364.

To foreclose the *equity*, a bill in chancery is exhibited, to which an answer is put in, and a decree being obtained, a master in chancery is to certify what is due for principal, interest, and costs, which are to be pursued by the decree, whereupon the premises are to be re-conveyed to the mortgagor; or in default of payment, the mortgagor is ordered to be foreclosed from all *equity of redemption*, and to convey the premises absolutely to the mortgagee. Law of Securities. p. 129. 133.

By stat. 7 Geo. II. cap. 20. after payment or tender by the mortgagor, of principal, interest, and costs, the mortgagee can maintain no ejectment, but may be compelled to re-assign his securities.

EQUITY, in *Mythology*, sometimes confounded with Justice, a goddess among the Greeks and Romans, represented with a sword in one hand and a balance in the other.

EQUIVALENT, is understood of something that is equal in value, force, or effect, to another.

Equivalence is of various kinds, in propositions, in terms, and in things.

EQUIVALENT *propositions*. See EQUIPOLLENCE.

EQUIVALENT *terms* are where several words that differ in sound have yet one and the same signification; as *every body was there*, and *nobody was absent*, *nihil non*, and *omne*.

EQUIVALENT *things*, are either *moral*, *physical*, or *fictitious*. *Moral*, as when we say that the commanding or advising of a murder is a guilt *equivalent* to that of the murderer.

Phyſical, as when a man who has the ſtrength of two men is ſaid to be *equivalent* to two men. *Statical*, where by a leſs weight becomes of equal force with a greater, by having its diſtance from the centre increaſed.

EQUIVOCAL, EQUIVOCUM, denotes a word or expreſſion that is dubious and ambiguous, or that may have ſeveral ſenſes, one true and another falſe.

Equivocal terms anſwer to what are otherwiſe called *homonyma*, or *homonymous terms*.

Such is the word *emperor*, which is both the name of a dignity, the proper name of a perſon, and the name of a plant. So alſo the Latin *gallus*, which ſtands indifferently for a *cock* and a *Frenchman*.

In theſe caſes, one word denotes two or more different ideas, or different ſorts of objects; whence that common definition of *equivocals* in the ſchools, *quorum nomen eſt commune, ratio vero eſſentiæ ſecundum illud nomen diverſa*. Philoſophers diſtinguiſh *equivocals* into *active* and *paſſive*; or *equivoca æquivocantia*, and *equivocata*.

Æquivoca æquivocantia, or thoſe that denominate and ſignify things, are words common to ſeveral things in a very different ſignification, i. e. to ſeveral things which have a ſimilar eſſence correſpondent to the ſimilar denomination. E. gr. The word *tenent*, which ſtands for a ſign, a mountain, and an animal; and in one ſignifies a lowing animal; in another, a heap of ſtones and earth; and in the third, a conſtellation or ſyſtem of ſtars.

Æquivoca æquivocata, or thoſe that are called or denominated, are the things ſignified by ambiguous names, e. gr. a ſign, a mountain, and an animal: which laſt ſpecies of *equivocals* alone Ariſtotle ſeems to have had in view in his definition, which agrees to theſe, and theſe only.

EQUIVOCAL *action* and *cauſe*. See ACTION and CAUSE.

EQUIVOCAL *generation*, is a method whereby animals and plants are ſuppoſed to be produced, not by the uſual way of coition between male and female, but by ſome ſuppoſed plaſtic power or virtue in the ſun, &c.

Thus, inſects, maggots, flies, ſpiders, frogs, &c. have ſometimes been ſuppoſed to be produced by the heat of the ſun warming, agitating, and impregnating the duſt, earth, mud, and putrefied parts of animals.

This method of generation, which we alſo call *ſpontaneous*, was commonly aſſerted and believed among the ancient philoſophers; but the moderns, from more and better obſervations, unanimouſly reject it, and hold that all animals, nay, and vegetables too, are univocally produced; that is, from parent animals, and vegetables of the ſame ſpecies and denomination.

It were a thing, one would imagine, ſufficient to diſcredit the Ariſtotelian, or rather the Egyptian doctrine of *equivocal generation*, to find flies, frogs, lice, &c. to be male and female, and accordingly to ingender, lay eggs, &c.

The doctrine of *equivocal generation* we call an *Egyptian doctrine*, as having in all probability had its riſe in Egypt, to ſolve the hypotheſis of the original production of men, and other animals, out of the earth, by the help of the ſun's heat.

To prove which, the Egyptians, as Diodorus Siculus obſerves, produce this obſervation, that about Thebes, when the earth is moiſtened by the Nile, and afterwards impregnated by the intenſe heat of the ſolar rays, an innumerable ſwarm of mice do come forth; whence he infers, that all kinds of animals might equally have riſen out of the earth at the beginning of things; and from theſe biſhop Stillingfleet takes the other writers and adherents to the doctrine of *equivocal generation*, Mela, Pliny, Ovid, &c. to have borrowed the hypotheſis with out enquiring into its truth. Derham's Phy. Theol. lib. iv. cap. 15.

EQUIVOCATION, *Æquivocatio*, the uſing of a term or expreſſion that has a double ſignification.

Equivocations are expedients to ſave telling the truth, and yet without telling a falſity. The fathers are great patrons of *equivocations* and mental reſervations, holding, that the uſe of ſuch ſhifts and ambiguities is in many caſes allowable.

St. Auguſtine, particularly, is reproached with endeavouring to vindicate Iſaac for ſaying his wife from a crime by an *equivocation*; *tacuit aliquid veri, & non dixit aliquid falſi*. To advance a dubious propoſition, knowing it will be underſtood in a ſenſe different from that you give it in your mind, is an *equivocation*, and a breach of good faith and ſincerity.

In moral theology, it is ſtrictly underſtood of a term or phraſe with two different ſignifications, the common and obvious, the other more unuſual and remote; the latter of which being underſtood by the ſpeaker, but the former by the hearers, they conceive ſomething different from one another.

Of this we have an inſtance in St. John, chap. xi. where our Saviour is repreſented as ſaying, *Lazarus ſleepeth*; for the diſciples who took the word *ſleeping* in the uſual ſignification, concluded that Lazarus, who, they had been told, was ſick, began to take reſt, and would ſoon recover; but Jeſus, uſing the word in a leſs direct and uſual ſignification, meant that Lazarus was dead.

When the *equivoque* conſiſts of ſeveral words, it is properly called an *amphibology*; of which we have an inſtance in St. John, chap. ii. *Deſtroy this temple, ſayth Jeſus, ſpeaking to the Jews, and I will raiſe it again in three days.*

The lawfulneſs of the uſe of of *equivocations* has been greatly diſputed among the modern caſuiſts; many grave authors deny that it is allowable to uſe them on any occaſion whatever. Their reaſon is, that an *equivocal* is to all intents and purpoſe the ſame thing with a lye.

EQUULEUS, or EQUULEUS, in *Antiquity*, a kind of rack, or engine of torture, uſed for extorting the truth; at firſt chiefly on ſlaves, but afterwards turned againſt the Chriſtians.

The patient's arms and legs being faſtened on the *equuleus* with cords, he was hoiſted aloft, and extended in ſuch manner that all his bones were diſlocated. In this ſtate, red hot plates were applied to his body; and he was alſo goaded in the ſides with an iron forked inſtrument, called *ungula*.

The *equuleus* was of wood, and had holes at certain diſtances, with a ſcrew, by which the criminal was ſtretched to the third, ſometimes to the fourth or the fifth hole at intervals, the ſcrew was ſlackened again, by which he had ſome reſpite; but then he was tormented with queſtions.

The *equuleus* in more ancient times was conſtructed in the form of a horſe; the criminal was laid on his back, and his arms were turned under the breaſt of the *equuleus*, his hands were bound, and his feet ſtretched out towards his tail. A rope, faſtened to the feet, was made to paſs over a ſmaller pulley between the hind-legs of the *equuleus*, and made to reſt over another larger pulley fixed under the belly by means of a handle, which the executioner turned round till all the bones, &c. were diſlocated. See a learned diſſertation on the form and uſe of this inſtrument, by Dr. Ward, in the Phil. Tranſ. vol. viii. part iv. p. 32, &c.

Hieronymus Magius, when a priſoner among the Turks, wrote an expreſs treatiſe De Equuleo; and another of Beſſi, merely as it is ſaid from his memory, without any aſſiſtance of books. Signolius had another treatiſe on the ſame ſubject.

EQUULEUS, EQUICULUS, and EQUUS *minor*, *equi ſeptus*, the *Horſe's Head*, in *Aſtronomy*, a conſtellation of the northern hemiſphere, whoſe ſtars in Ptolemy's Catalogue are 4, in Tycho's 4, in Hevelius's 6, and in Mr. Flamſteed's 10. The longitudes, latitudes, magnitudes, &c. are as follow:

Names and ſituations of the ſtars.	Figures of Chr.	Signs.	Longit.	Latitude North.	Magnitude.
			° ′ ″	° ′ ″	
		♓	14 18 57	20 32 56	5
			15 59 37	23 2 30	5
			16 2 30	21 16 30	6
			16 25 37	11 38 32	6
Preced. of two in the mouth.	γ		19 6 24	25 13 22	4
		♈			
			19 7 3	25 6 52	6
Subſeq. of the ſame.	β		20 7 50	24 47 57	4
Preced. of two in the head.	α		18 47 48	20 9 50	5
			20 51 52	21 42 58	6
Subſeq. in the ſame.	δ	♉	21 7 2	11 3 6	4

EQUULEUS, in *Arts* and *Manufactures*. See HORSE.

EQUUS, in *Zoology*. See HORSE.

EQUUS *marinus*, in *Zoology*, a name given by ſome to an animal very different from the hippopotamus, or river-horſe, and more uſually known by the name of the MORSE.

ERA, in *Chronology*. See ÆRA.

ERANDGAAS, in *Ornithology*, the name of a fowl, of the gooſe kind, deſcribed by ſome authors. It is ſaid to be ſomewhat ſmaller than the common wild gooſe: its head grey, and its neck adorned with a red ring: its breaſt, wings, and neck, are grey, and its feet red. Mr. Ray much ſuſpects the account of this bird. Ray's Ornithol. p. 308.

ERADICATIVE, in *Medicine*. See RADICAL.

ERANARCHA, a public officer among the ancient Greeks, whoſe buſineſs was to preſide over and direct the alms given, and proviſions made for the poor.

The word is formed of ἔρανος, *alms, contribution*, and ἄρχω, *command*.

The *eranarcha* was properly the adminiſtrator, or ſteward of the poor: when any perſon was reduced to poverty, taken captive, or had a daughter to marry, which he could

could not effect for want of money, &c. this officer called an aſſembly of friends and neighbours, and taxed each, according to his means and eſtate, to contribute towards his relief. This is what we learn from Cornelius Nepos, in his life of Epaminondas.

ERANTHEMUM, in *Botany*, a name given by ſome authors to the flos Adonis, or red maſſlies. See PHEASANT'S *eye*.

ERARIUM. See ÆRARIUM.

ERASED, in *Heraldry*, expreſſes any thing that ſeems violently torn off from its proper place. It is uſed in contradiſtinction to *couped*, which ſignifies a thing clean cut off. The family of Card bears ermine, a demy lion, rampant *eraſed*, azure, &c.

ERASTIANS, a religious ſect, or faction, which aroſe in England during the time of the civil wars in 1647, thus called from their leader Thomas Eraſtus, whoſe diſtinguiſhing doctrine it was, that the church had no right to diſcipline, that is, no regular power to excommunicate, exclude, cenſure, abſolve, decree, or the like.

ERATO, from ἐραω, *I love*, in *Mythology*, the name of one of the nine Muſes who preſided over love-poetry. To this Muſe ſome have aſcribed the invention of the lyre and lute; and ſhe is repreſented with a garland of myrtles and roſes, holding a lyre in one hand, and a bow in the other, and at her ſide a Cupid with his torch. There is alſo a NEREID of the ſame name.

ERCEUS, of ερκος, *ſeptum*, in *Mythology*, the name by which thoſe who were appointed to guard the walls of a city invoked Jupiter.

EREBENNUS, Ἐρεβεννος, a name given by Galen and ſome other of the Greek writers, as a diſtinctive epithet for the black chamæleon thiſtle, which was eſteemed poiſonous, and was by this word diſtinguiſhed from the ἀγελαιος or white chamæleon, which was an eſculent plant, and uſed by ſome as an antidote. It has happened, however, that the white chamæleon thiſtle has been by ſome called a poiſon, as well as the black; but this is only owing to a miſtake of Pliny, in ſuppoſing the effects of birdlime to have been attributed to this plant, becauſe of its yielding a viſcous, but ſafe gum, at its root. It was called by ſome *ixias chamæleon*. See IXIAS and CHAMÆLEON *thiſtle*.

EREBUS, Ἐρεβος, from ערב, *night*, in *Mythology*, a term denoting darkneſs. According to Heſiod, *Erebus* was the ſon of Chaos and the night, and the father of the day. This was alſo the name of part of the *infers* among the ancients: they had a peculiar expiation for thoſe who were detained in *Erebus*.

Erebus was properly the gloomy region, and diſtinguiſhed both from Tartarus, the place of torment, and Elyſium, the region of bliſs: according to the account given of it by Virgil, it forms the third grand diviſion of the inviſible world beyond the Styx, and comprehends ſeveral particular diſtricts, as the *limbus infantum*, or receptacle for infants; the *limbus* for thoſe who have been put to death without cauſe; that for thoſe who have deſtroyed themſelves; the fields of mourning, full of dark groves and woods, inhabited by thoſe who died for love; and beyond theſe, an open champaign country for departed warriors. Æn. lib. vi. p. 427, &c.

ERECT *flowers*, are ſuch as grow upright without hanging or declining the head. See FLOWER.

ERECT *leaf*, *erectum folium*, among *Botaniſts*. See LEAF.

ERECT *viſion*. See VISION.

ERECT, *direct*, and *declining*, &c. *dials*, &c. See DIAL.

ERECTION, the act of raiſing or elevating a thing in a right line.

The *erecting* of a perpendicular on a line given, is a popular problem in geometry.

The term *erection* is alſo uſed figuratively; as the *erection* of a marquiſate into a duchy; biſhopricks can only be *erected* by the king.

ERECTION is particularly uſed in *Medicine*, for the ſtate of the penis when ſwelled and diſtended by the action of the muſcles, called *erectores*.

There is alſo an *erection* of the clitoris which is performed by muſcles provided for that purpoſe. See CLITORIS and ERECTORES.

An alternate ſtate of *erection* and flaccidity in the penis, Dr. Drake obſerves, is of abſolute neceſſity, the firſt to the performance of its office, the ſecond for the ſecurity of the part.

Without an *erection* it were impoſſible to emit and lodge the ſeed where it ought to be; and with a conſtant one, almoſt as impoſſible to ſecure the part from external injuries. To ſay nothing of the loſs of inſtigation, which muſt be a neceſſary conſequence of conſtant *erection*.

The *erection* of the penis conſiſts in a diſtenſion of its corpora cavernoſa, by an extraordinary quantity of blood pent up therein.

That the blood is the matter which diſtends the penis in *erection*, is evident from abundance of experiments; though the moſt convincing is that of firmly tying the penis of an animal (as has been frequently done to a dog) in coitu, wherein nothing has been found but blood to diſtend it. Hence, in the bodies of criminals, that hang long after death, the penis becomes *erected*; the blood in that poſition falling to the inferior parts, and ſtopping there. By blowing into the blood-veſſels of the penis after death, the part becomes *erected*. This was firſt diſcovered by Mr. Cowper, upon viewing its veins; after he had diſtended them with wind; whence it plainly appeared, that the external trunks paſſed, ſome under its ſkin only, and ſome over the oſſa pubis; beſides, that a vaſt number of other veins on the dorſum penis unite and empty themſelves into one trunk, called *vena penis*, which paſſes immediately under a tranſverſe ligament of the oſſa pubis, which is compreſſed by the approximation of the dorſum penis to the ligament of the pubis. This application of the dorſum penis is effected by its muſcuſi directores pulling down the crura of the corpora cavernoſa penis, which are tied up at their juncture in the body of the penis to the os pubis by the ligamentum ſuſpenſorium. Now, this cannot happen to the cavernous body of the urethra, becauſe there is no bone whoſe poſition can give riſe to a ligament which can have that effect on its veins; wherefore, the muſculi accelaratores embracing the veins of the bulb, do that office, though not ſo effectually as in the penis itſelf.

Accordingly the glans is not always perfectly diſtended with the penis, and it is this part that ſooneſt becomes flaccid on an *erection*.

The blood by ſuch means being preeluded from its return, the corpora cavernoſa muſt of neceſſity become diſtended, if we conſider their ſtructure above mentioned with reſpect to the veins. The arteries, which before were flaccid, have now their trunks alſo diſtended, and do more plentifully import blood into the corpora cavernoſa.

But ſince it is abſolutely neceſſary ſome part of the detained blood ſhould be ſtill paſſing off, leſt it become grumous, and unfit for a reflux; the venæ præputii communicate with thoſe of the penis itſelf, whereby part of the blood may be returned from the penis during its *erection*, and give way to a freſh ſupply from the arteries, and preſerve the circulation uninterrupted.

ERECTORES *clitoridis*, in *Anatomy*, a pair of muſcles ariſing from the protuberances of the iſchium, and inſerted into the ſpongious body of the clitoris, which they ſerve to erect in coition. See CLITORIDIS *muſculi*, and CLITORIS.

ERECTORES *penis*, in *Anatomy*, a pair of muſcles, ariſing fleſhy from the protuberances of the iſchium below the beginning of the cavernous bodies of the yard, into whoſe thick membranes they are inſerted.

Their uſe is to pull the yard upwards towards the os pubis, whereby the greateſt vein is compreſſed, and the reſluent blood denied its paſſage under thoſe bones, which makes it ſwell. See ERECTION.

EREGMOS, from ἐρεγω, *I break*, a word uſed by the ancients, to expreſs a bean decorticated and broken into ſmall pieces, in order to be boiled in piſſans. This name was not, however, kept ſtrictly to this ſenſe, but they applied it indifferently to all the leguminous fruits broken in the ſame manner. Foeſius will have it to ſignify *bean-meal*, but others are againſt this; and Galen in ſome places uſes it only to expreſs a bean divided into two parts.

EREMIT. See HERMIT.

ERETHISMOS, from ερεθιζω, *I irritate*, a word uſed by Galen and Hippocrates to expreſs any thing that irritates. Galen ſays that Hippocrates means by it alſo every thing that reduces the habit of body to an infirm ſtate, among which are to be reckoned before all other things, irritating, acrimonious, and pungent humours in the ſtomach and bowels, particularly in the mouth of the ſtomach, worms aſcending from the inteſtines into the ſtomach, nocturnal itchings of the whole ſkin, or of ſome part of it, which, by their irritation and prevention of ſleep, greatly exhauſt ſtrength.

ERETRIA *terra*, *Eretrian earth*, in the *Materia Medica*, the name of a very peculiar kind of alkaline bole, dug in the Negropont, near the ancient *Eretria*, and once in great uſe as an aſtringent and a ſudorific.

The ancient writers in medicine all mention the *Eretrian* earth, and Dioſcorides and Galen deſcribe two kinds of it, a grey and white. The grey is what is properly diſtinguiſhed by this name, being an earth of a different kind from all the other boles. The white, though the ancients ſeem not to have obſerved it, yet was plainly from their own deſcriptions, the ſame with the white bole armenic, though found in a different place. Hiſt. Foſſ. p. 5.

The

The grey or genuine *Eretrian* earth is a fine and pure greyish white earth, moderately heavy, naturally of a ſmooth ſurface, of a friable texture, eaſily crumbling to pieces between the fingers, but not ſtaining the ſkin in handling; it ſticks ſtrongly to the tongue, but melts to a butter-like ſubſtance in the mouth; it burns to a perfect ſnow-white, and effervesces violently with aqua fortis. But what abundantly diſtinguiſhes it from all other earths, is, that if a little be wetted, and drawn over a plate of braſs or copper ſo as to mark a line, the mark will in a little time appear bluiſh. This is recorded of it ſo early as in the writings of Dioſcorides, and experiment proves it to be true. It ſeems plainly to be owing to an alkaline quality in the earth: this it plainly manifeſts by its fermenting ſo ſtrongly with acids; and it is well-known that alkalines draw a blue tincture from copper.

The ancients all eſteemed it a great medicine, and were particularly careful in their way of preparing it for uſe, by frequent waſhing. It is now unknown in the ſhops; but its highly alkaline quality, in which it is ſo much ſuperior to all the earths now in uſe, might make it worth the bringing into uſe again; and it may ſtill be had in its old place, in almoſt any quantities.

ERGALIA, of ἔργον, *opus*, a word uſed by the *Alchemiſts*, to expreſs that part of their treatiſes which explains the inſtruments employed in their operations.

ERGASIMA, a name given by Dioſcorides and other of the ancients to a very foul and coarſe kind of myrrh.

ERGASTERIUM, a word uſed by the writers in *Chemiſtry*, ſometimes to expreſs the whole elaboratory, and ſometimes that part of a furnace on which the bottom of the retort, copel, or crucible, is to reſt in an operation.

ERGASTINÆ, Ἐργαστῖναι, in *Antiquity*, a ſelect number of virgins employed in weaving Minerva's peplus or robe, which was carried in proceſſion at the Athenian feſtival *Panathenæa*. See PEPLUS, and PANATHENÆA.

ERGASTULUM, among the ancients, a houſe of correction, or work-houſe, where ſlaves, by the private authority of their maſters, were confined and kept at hard labour for ſome offence. It was likewiſe called *ſophronifterium*.

ERGATTA, Ἐργαστὴς, in *Antiquity*, a Laconian feſtival in honour of Hercules.

ERGOT, in the *Manege*, is a ſtub like a piece of ſoft horn, about the bigneſs of a cheſnut, placed behind and below the paſtern joint, and commonly hid under the toft of the fetlock. To *diſergot*, or take it out, is to cleave it to the quick with an inciſion-knife, in order to pull up a bladder full of water that lies covered with the *ergot*. This operation is ſcarcely practiſed at Paris, but in Holland is frequently performed upon all four legs, with intent to prevent watery ſores and foul ulcers.

ERGOT, in *Medicine*, the name given by the French to a diſeaſe ſimilar to one in England, proceeding from eating vitiated rice. See Phil. Tranſ. vol. lii. part ii. and vol. lv. art. 17. p. 106. See BERIBERY and SHUPY.

ERIACH, in *Antiquity*, the name of a recompenſe aſſigned by the high NEATHON *law* in caſe of murder, to the friends or to the child or wife of him that was ſlain, as a kind of compoſition between the murderer and his proſecutors.

ERICA, in *Botany*. See HEATH.

ERICA *marina*, *ſea-heath*, a name given by many authors to a very beautiful ſea-plant of the fucus kind, called by Mr. Ray and ſome others the SUCUS *ericæ folio*. This differs ſo much in bigneſs in different places, that it has been ſuſpected to be of two diſtinct ſpecies; thoſe plants of it which are found about the ſhore ſeldom exceeding ten inches in length, and thoſe in deeper water often growing to three feet.

It is compoſed of a vaſt number of ramifications; the bottom ſtalk is woody, and often of the thickneſs of a man's little finger; yet even in theſe there is no diſtinction of nerves or fibres; the large branches are rough and knotty, and ſend off many other ramifications, the larger of which are round, but the extreme ones flat.

At different places over this plant, one obſerves certain knots or tumors; theſe are no other than the branch in that part ſwelled, and the uſe of the ſwelling is to contain the capſules which incloſe the ſeed; theſe, and their arrangement in theſe ſwellings, are wholly like thoſe of the common fucus, and there are uſually ten or twelve capſules contained in every ſwelling or bladder of the ſtalk. They are not arranged with any regularity in the ſwelling, but are always found nearer the upper than the lower extremity of it. The ſeeds are round, and a very great number of them are contained in every capſule.

The ſwellings which contain theſe capſules are ſometimes placed at conſiderable diſtances from one another on the ſtalks of the plant, and ſometimes they ſtand ſo cloſe as to repreſent the beads of a necklace. Some branches of the plant alſo are very full of them, and others ſcarce have any at all upon them. Sometimes the bladders are found empty on this plant, as they are in the common ſea wrack; but in this caſe there may always be ſeen the marks of the places where the capſules have once been, though ſince periſhed by ſome acrid nit. Mr. Reaumur, who gives this deſcription of this plant, never ſaw its flowers; but there ſeems no doubt but that they are compoſed of ſhort filaments, like thoſe of the other plants of this kind; and his not examining the plant at a proper ſeaſon was probably the reaſon of his not finding anatomy for the flowers and ſeeds of theſe plants are uſually both large enough to be ſeen by the naked eye; and where the ſeed is ſo, in moſt caſes the flower is alſo. Mem. Acad. Par. 1712.

ERICA, in *Ichthyology*, a name given by Gaza and ſome others, as the interpretation of the chalcis of Ariſtotle, that is, as the name of the common HERRING.

ERICERUM, a name given by Actius and other authors, to a ſort of collyrium, uſed in weakneſs of the eyes, in which the *herb erica* or *heath* was an ingredient.

ERICHTHONIUS, in *Aſtronomy*, a conſtellation, the ſame as AURIGA.

ERIDANUS, in *Aſtronomy*, a conſtellation of the ſouthern hemiſphere, in form of a river.

The ſtars in the conſtellation *Eridanus*, in Ptolemy's Catalogue, are 34; in Tycho's, 19; in the Britiſh Catalogue, 84; the longitudes, latitudes, magnitudes, &c. whereof are as follow:

		Longit.		Latitude South.		Magnitudes.
Names and ſituations of the ſtars.		♈ ° ′ ″		° ′ ″		
Firſt from the turn of the river to the breaſt of Cetus.	♈	7 43 50	32	46 5	4	
A ſecond.	♉	28 17 41	35	32 44	4

ERIFFS, a name given to canary birds when about two years old. See CANARY *bird*.

ERIGENS *penis*. See ERECTORES *penis*.

ERIGERON, or SENECIO. See GROUNDSEL.

ERINACEA, in *Botany*, the name of a genus of plants, the characters of which are these: the flowers and fruit are the same with those of the broom; but the whole plant is so beset with prickles as to resemble a hedge-hog. Tourn. Inst. p. 646.

According to Mr. Tournefort there are two species.

ERINACEUS, in *Zoology*. See *Hedge*-HOG.

ERINACEUS, is also a name given by Dillenius and some other botanists to the pectinated agarics, called by others *hydnum*. These differ from the agarics, properly so called, which are lamellated underneath, and from others which are porous, for these are echinated, or beset with pointed prickles.

ERINGO, in *Botany*. See ERYNGO.

ERINOPTERUS. See PRIVET-*fly*.

ERINUS, in *Botany*, a genus of the *didynamia angiospermia* class. Its characters are these: the flower hath a five-leaved empalement, and one tubulous petal, which is of the ringent kind, cut into five equal segments, and is short and reflexed: it hath four stamina situated within the tube, two of which are a little longer than the other. In the bottom of the tube is situated an oval germen, which afterwards becomes an oval capsule, with two cells filled with small seeds. Miller. There are four species.

ERIOCAULON, in *Botany*, a genus of the *triandria trigynia* class. The characters of which are, that the calyx is common; that it has a small imbricated head, three equal petals, and the stamina above the germen. There are five species.

ERIOCEPHALUS, in *Botany*, Dill. Hort. Elth. 110. a genus of the *syngenesia polygamia necessaria* class. Its characters are these: it hath a radiated flower, composed of female half florets, which form the rays, and hermaphrodite florets which form the disk: the hermaphrodite flowers are funnel-shaped, and cut into five parts at the brim, and have five stamina, with a naked germen. The female florets have their petals stretched out on one side like a tongue, divided at the end into three small lobes; they have no stamina, but an oval naked germen: they have one naked seed sitting on the naked plain receptacle; There are three species. These plants retain their leaves all the year, and so add to the variety of exotics in the winter season.

ERIOPHORUM, in the Linnæan system of *Botany*, the name of the cotton-grass, or cotton-rush, common in marshy places, and called *linagrostis* by other writers. This is, by that author, made a distinct genus of plants, of the *triandria monogynia* class, whose characters are, that the flower-cup is an imbricated spike, made up of oblong oval scales, a little bent in, and separating the flowers: it has no petals; the stamina are three capillary filaments; the antheræ are erect and oblong; the germen of the pistil is extremely small; the style is thread-like, and of the same length with the scales of the cup; the stigmata are three, longer than the style, and bent backward; the seed is three cornered, pointed, and covered with hairs longer than the spike. There are five species.

ERIOPHORUS, in *Botany*, a name given by Valiant to a genus of plants, since described by Linnæus under the name of *andryalo*. See ANDRYALA and *Sow*-THISTLE.

ERIOX, or EROX, in *Ichthyology*, a name given by Albertus and some other authors to the common salmon, called by others, *antharagus*, and *salmo*. See SALMON.

ERISTALIS, in *Natural History*, the name of a stone, mentioned by Pliny and the ancients, and of which a very memorable quality is recorded by them, which is, that though it was naturally white, it would occasionally turn red.

ERISTICI, from ἐρις, *dispute*, in *Botany*, such authors as have attempted the study of that science in a philosophical way, and have been publicly engaged in disputes about the true foundation of its several distinctions, &c.

ERITHACE, a name given by the ancients to the yellow matter collected on the hinder legs of the bees after their excursions in search of the materials for their hives; we usually esteem this to be real wax, and the French call it *cire brute*, or *rough wax*: it is certain, however, that though the matter of which wax is to be formed is contained in this substance; yet the Dutch and some other nations have the most just idea of it, in calling it *pain de abeilles*, or *the food of the bees*.

This substance is only the farina of flowers, and no experiment has been able to separate real wax from it. The most probable opinion concerning it is, that it serves the bees as food, and that after this it is converted in their bowels into the substance called wax.

ERITHALIS, in *Botany*, a genus of the *pentandria monogynia* class. The corolla is divided into five segments, the calyx is arecolated, and the fruit is a berry consisting of ten cells. There is one species.

ERMESIA, a name given to a composition used among the ancients, and famous for its effects in making people beget handsome children. It consisted of honey, myrrh, saffron, and palm-wine, all beat together. This mass was to be taken mixed in milk. The women took it as well as the men, and many had great faith as to its effects.

ERMIN, or ERMINE, in *Heraldry*, denotes a white field or fur, powdered or interspersed with black spots, called powdering. See FUR.

It is supposed to represent the skin of an animal of the same denomination. In effect, there is no animal whose skin naturally corresponds to the herald's *ermin*.

The animal is milk white, and so far as it from having spots, that tradition reports, that it will rather die, or be taken than fully its whiteness. Whence its symbolical use. But white skins having for many ages been used for the linings of the robes of magistrates and great men; the furriers at length, to add to their beauty, used to sew bits of the black tails of those creatures upon the white skins, to render them the more conspicuous. Which alteration was introduced into armoury. See *Tab.* II. *Herald. fig.* 60.

The fable spots in *ermin* are not of any determinate number, but they may be more or less at the pleasure of the painter or furrier.

ERMIN, an order of knights, instituted in 1450, by Francis I. duke of Bretagne, and formerly subsisting in France. The collar of this order was of gold, composed of ears of corn in saltier; at the end of which hung the *ermin*, with this inscription, *a ma vie*. But the order expired when the dukedom of Bretagne was annexed to the crown of France.

ERMINE. A *cross ermine* is a cross composed of four *ermine* spots, placed in the figure represented *Tab.* II. *Herald. fig.* 62.

It must be observed, that the colours in such arms are not to be expressed, because neither the cross nor the arms can be of any colour, but a white and black.

Colombiere blazons it *gautre queues d'ermine en croix*.

The editor of Guillim describes it thus; a cross of four *ermines*;

ermines; or, more properly, four *ermine* spots in crofs. It is the coat of Hurlton in Cheshire.

ERMINE, *timbre of*. See TIMBRE.

ERMINES, is used by fome Englifh writers for the reverfe of *ermine*, i. e. for white fpots on a black field; but on what foundation nobody can tell; for the French, from whom we have our heraldry, have no fuch term; but call this black powdered with white, *contre-ermine*, as denoting the counter, or reverfe of *ermine*; which is white powdered with black. See *Tab.* II. *Herald. fig.* 63.

ERMINEUM *animal, feta, or ermine*, the creature whofe fkin is the *ermine*, fo much eſteemed as a fine fur. See *Tab. Quad.* N° 9.

This creature is properly a fpecies of weafel, and is called by Mr. Ray, and other authors, *muſtela candida*, the *white weaſel*, and by Linnæus *muſtela erminea*. It is in all refpects like the common weafel, and is all over of a pure fnow white, except the tip of the tail, which is of as beautiful a black, and that it has a little yellowifh grey about the eyes, and a mark, or fpot, of the fame colour on the head, another on the fhoulders, and a third, near the tail. Its colour is, however, very different in degree and elegance, according to the feafon of the year. It is frequent about rivers, and in meadows, in thofe countries which produce it, and feeds on moles, mice, and other fmall animals. The fkins and tails are a very valuable article of commerce in Norway, Lapland, and Ruffia, and other cold countries, where they are found in prodigious numbers, and regularly change their colour in winter, becoming white. In Siberia, they burrow in the fields, and are taken in traps, baited with flefh. In Norway they are fhot with blunt arrows, or taken in traps. The *feta* is fometimes found white in Great Britain, and called the *white weaſel*.

ERMINITES fhould feem a diminutive of *ermines*, and naturally to fignify little *ermines*; but it is otherwife. *Erminites* expreſſes a white field powdered with black; only that every fpot has a little red hair therein.

Some authors ufe the word *erminites*, for a yellow field powdered with black; which the French expreſs much better by *or ſemée d'ermines de ſable*.

ERMINOIS expreſſes an or field, with fable powdering.

ERNES, in our *Old Writers*, fignify the loofe feathered ears of corn that are left on the ground, after the binding or cocking of it.

It is derived from the old Teutonic *ernde, harveſt*; *ernden, to eat or mow corn*. Hence *erwis*, in fome places, to glean.

ERODINUM, a word ufed by fome of the enthufiaftic writers in alchemy, to fignify the prognoſtic, good or bad of any operation.

EROS, of ἔρως, *love*, in *Mythology*, one of the two chiefs over all the other Cupids, being the caufe of love. See ANTEROS.

EROSION, in *Medicine*, the act of fharp, acrid fluids, or humours, gnawing or tearing off parts from the flefh, and other fubftances. Arfenic, and other poifons, make *eroſions* in the inteſtines. See CORROSION.

EROSUM, *folium*, among *Botaniſts*. See LEAF.

EROTESIS, ἐρώτησις, in *Rhetoric*, the fame with INTERROGATION.

EROTIA, ἔρωτια, a feſtival among the Greeks, in honour of Cupid, being celebrated every fifth year with fports and games.

EROTIC, derived from ἔρως, *love*; whence ἐρωτικὸς, is applied to any thing which has a relation to the paſſion of love.

In *Medicine*, we particularly ufe the phraſe *delirium eroticum*, for a kind of melancholy contracted through exceſs of love.

Though among the ſeveral ſpecies of pulſes, there be no amorous pulſe, that is, no pulſe peculiar to that paſſion; yet we can certainly diſcover where the diſorder is *erotic* by the beating of the pulſe, which, in that caſe, is changeable, unequal, turbulent, and irregular. Speak to the patient of the perſon he loves, and his pulſe inſtantly changes, becoming higher and quicker; and the minute you change the converſation the pulſe is loſt again, and is diſturbed anew.

EROTIDIA, ἐρωτίδια, the fame with *erotia*.

EROTYLOS, in *Natural Hiſtory*, the name of a ſtone, of which we have no deſcription left us, but which the ancients are ſaid to have uſed in diſination.

EROWA, the name of a kind of nettle which grows in the mountains at Otaheite in the South Sea, with which the inhabitants make fiſhing lines, which ſerve to hold the ſtrongeſt and moſt active fiſh, and are much ſtronger than our ſilk lines of twice the thickneſs.

ERRANT, in *Law*, the ſame with *itinerant*; the term is attributed to judges who go the circuit; and to bailiffs at large.

ERRANTS, *knights*. See KNIGHT.

ERRATA, a liſt uſually placed at the beginning or end of a book, containing the faults that have eſcaped in the impreſſion, and, ſometimes, even in the compoſition of the work.

Lindenberg has an expreſs diſſertation on typographical errors, De Exteribus Typographicis; wherein he obſerves, that there is no book exempt from them, not even the ſacred books. He lets himſelf to enquire into all the cauſes thereof; and propoſes means to prevent them. But he advances nothing on that article, but what is either common or inſpracticable.

ERRATIC, in *Aſtronomy*, an epithet applied to the planets, which are called *erratic*, or wandering ſtars, in contradiſtinction to the fixt ſtars.

ERRATIC *fevers*, in *Medicine*, a term uſed to expreſs ſuch fevers as, according to the language of medical writers, obſerve no regular type, that is, are not determinate either in their attacks or in their general period. They are thus called by way of diſtinction from the typic fevers, which are regular in both. See FEVER.

ERRATIC *wood*. See WIND.

ERRHINA, *Fibrin*, from ἐν, *in*, and ῥὶς, *noſe*, in *Medicine*, are remedies taken by the noſe to enliven the ſpirits, ſtop bleeding, &c. but principally to purge the humidities of the head, and by the general ſhock they occaſion, to remove the moſt diſtant obſtructions. Hence reſults their uſe in lethargies, epilepſies, palſies, apoplexies, headachs, vertigoes, catarrhs, gutta ſerena, &c.

Of theſe, ſome are taken in powders, as betony, tobacco, marjoram, iris, white hellebore, euphorbium, &c. Others in a liquid form, made of the juice of marjoram, ſage, beer, cyclamen, iris, &c. Others in form of liniments, incorporated with unguent. roſat. Others ſolid, formed like pyramids, to ſtop bleeding at the noſe; compoſed of Armenian bole, terra ſigillata, maſtic, human or hogs-blood dried, &c. Such *errhines* as are dry, and made up in powders to excite ſneezing, are properly called *ſternutatories*. Some moderns call them *capnotargia*.

ERRIPSIS, from *ſurvo, I precipitate*, in *Medicine*, is uſed in different ſenſes, ſometimes for a weakneſs of the whole body, ſometimes only of ſome one part. When applied to the whole body, it expreſſes that utter dejection and proſtration of ſtrength which makes a man fall down like a dead carcaſs; and, when applied to the eyes, it expreſſes ſuch a debility, as renders it impoſſible to keep them open.

ERROR, a miſtake of the mind, in giving aſſent to a thing, or propoſition, which is not true. See FALLACY.

Some philoſophers define *error* an act of the mind, whereby things that ſhould be joined, are ſeparated; or, things that ſhould be ſeparated, are joined; or a wrong judgment, diſagreeing with the things whereon it is paſſed.

Error ſtands in oppoſition to *truth*, which conſiſts in an agreement between the propoſition, and the thing whereof it is affirmed or denied.

However, a bare failure, or non-attainment of truth, doth not conſtitute *error*; that being common both to ignorance and doubting.

Error only ſtands diſtinguiſhed from *falſhood*, in that the former is in the mind, and the latter only in the propoſition.

The great origin of all *error*, i. e. of believing that to be true, which is falſe, is a liberty or power, in the human mind, of giving its aſſent to ideas, or propoſitions, that are obſcure, as if they were perſpicuous and plain.

Particular cauſes of *error* are, inadvertency, prejudice, impatience, intereſt, authority, education, &c. See FAITH, PROBABILITY, OPINION.

Againſt all which, there is this one general rule or caution laid down, by F. Malebranche and others; viz. never to give our full aſſent to any propoſition, unleſs the evidence for it be ſo ſtrong, as that we can no longer with hold it, without incurring the ſecret reproaches of our own reaſon.

Mr. Locke reduces the cauſes of all our *errors* to theſe four; viz. 1. Want of proofs. 2. Want of ability to uſe them. 3. Want of will to uſe them. And, 4. Wrong meaſures of probability.

F. Malebranche conſiders five occaſional cauſes of *error*, or rather five different kinds of *errors*, accommodated to the different manners we have of perceiving things. 1. *Errors of ſenſe*. 2. Of the *imagination*. 3. Of the *underſtanding*. 4. Of our *inclinations*. And, 5. Of the *paſſions*. See SENSE, IMAGINATION, UNDERSTANDING, INCLINATION, and PASSION.

ERRORS, *popular*. See POPULAR.

ERROR, in *Law*, generally denotes a fault, or overſight, either in pleading, or in proceſs; upon either of which is brought a writ by way of remedy, called a *writ of error*; in Latin, *de errore corrigendo*.

Fitzherbert defines a writ of *error* to be, that which lies to redreſs falſe judgment given in any court of record, having

having power by charter, or preſcription, to hold pleas of dent of treſpaſs of above twenty thillings. There is alſo a *writ of error* for reverſing a fine, &c.

ERROR, *to aſſign.* See ASSIGNING.

ERRORS, *clerk of the.* See CLERK.

ERROR *loci*, a term often uſed by Boerhaave. This author obſerves, that in the body there is a decreaſing ſeries of veſſels; by which he means, that the firſt orders of the veſſels are adapted to receive the red globules of the blood, while the reſt are, perhaps, ſmaller and receive only the ſerum, the next in order the lymph, and the next the yet finer fluids. Now when the red globules of blood are propelled into the veſſels deſtined only to receive the ſerum, or when the ſerum gets into thoſe veſſels in which a finer fluid ought only to circulate; this he calls an *error loci*, and attributes much to it.

ERUCA, in *Zoology*. See CATERPILLAR.

ERUCA *marina groſſa groſſa*. See APHRODITA.

ERUCA, in *Botany*. See ROCKET.

ERUCAGO, in *Botany*. See BUNIAS.

ERUCTATION, *Belching*, the ſame as RUCTATION.

ERUDITION, denotes learning, or knowledge, and chiefly that of hiſtory and antiquity, of languages and of books, which is the reſult of hard ſtudy, and extenſive reading. The Scaligers were men of deep *erudition*; the writings of M. Launoy, a prieſt of the Oratory, are full of *erudition*.

Mr. Locke ſays, it is of more uſe to fill the head with reflections, than with points of *erudition*. If the mind be not juſt and right, ignorance is better than *erudition*, which only produces confuſion and obſcurity. M. Balzac calls a heap of ill choſen *erudition*, the luggage of antiquity.

ERUPTION, in general, a burſting forth, or exclufion of ſomething that was before covered and concealed.

In *Medicine*, it denotes a ſudden and copious excretion of humours, as pus or blood, and any breaking out of puſtules or ſpots in various diſorders; as in the ſmall-pox, meaſles, plague, fevers, &c. See EXANTHEMA.

The *eruption* of volcanos, or burning mountains, is frequently the effect, and iſſue, of earthquakes. See EARTHQUAKE, &c.

The *eruptions* of mount Ætna, and Veſuvius, are obſerved to be ſomewhat periodical: they are of two kinds; the one leſs violent, happening once in two or three months, and laſting uſually three or four days without much damage to the adjacent country. The other more furious, and of longer continuance, happening to mount Veſuvius about once in eighty years. That in 1362 was ſo violent, that by the beſt of S. Peccacio's obſervations, it caſt the rocks three miles into the air. Hartop, in Phil. Tranſ. N° 202.

The honourable Mr. Hamilton has communicated ſeveral accounts of later eruptions of Veſuvius to the Royal Society, which may be ſeen in the Phil. Tranſ. for 1767, 1768, and 1769. He obſerves that the violent *eruption* in 1767, is reckoned to be the twenty-ſeventh ſince that which deſtroyed Herculaneum and Pompeii, in the time of Titus. See VOLCANOS.

Mr. Oldenburg gives us an hiſtorical account of the ſeveral *eruptions* of mount Ætna, recorded in authors. The firſt whereof we have any credible account, was at the time of the expedition of Æneas, deſcribed by Virgil, Æneid. lib. iii. The ſecond, deſcribed by Thucydides, was four hundred and ſeventy-ſix years before Chriſt. In the time of the Roman conſuls there were four; another in Cæſar's time, ſo fierce, that Diodorus aſſures us, the ſhips near the iſland of Lipara were injured with the extreme heat of the water; another under Caligula; another at the time of the martyrdom of St. Agatha, ſaid to have been ſtopped at her interceſſion; another in the year 812; ſeveral between the years 1160 and 1169; others in 1284, 1329, 1408, 1444, 1536, 1633, 1660. Phil. Tranſ. N° 48.

Another extraordinary *eruption* happened in 1669, particularly deſcribed in the ſaid Tranſactions, N° 51. It was preceded for the ſpace of eighteen days, with a dark thick ſky, thunder, lightning, and frequent conculſions of the earth; the place of the *eruption* was twenty miles from the old mouth.

The matter here yielded, was a ſtream, or river, of melted metals and minerals, rendered liquid by the fierceneſs of the fire, and boiling up, and guſhing forth, as water does at the head of ſome great river; till having run in a full body for a ſtone's caſt, or more, the extremity thereof began to cruſt and curdle, and turned, when cold, into hard, porous ſtones, called *ſciorri*, as reſembling huge cakes of ſea-coal, full of a fierce fire. Theſe came rolling and tumbling over one another, and where they met a bank, wall, building, &c. would fill up, and ſwell over; by their weight bearing down any common building, and burning up what was combuſtible. The progreſs of this inundation was at the rate of a furlong a day; which it continued for fifteen or twenty days, running, at firſt, into the ſea, but afterwards into the city of Catanea; in its courſe it overwhelmed fourteen towns and villages, containing three or four thouſand inhabitants. The noiſe of the *eruption* at the mouth was heard ſixty miles.

Dr. St. Clair, in the Philoſophical Tranſactions, gives an account of a conſtant *eruption* of fire on one ſide of one of the Apennines, between Bologna and Florence; a ſpot of ground three or four miles in diameter, he obſerves, inceſſantly ſends up a flame, riſing very high, without noiſe, ſmoke, or ſmell, though it gives a very great heat. In great rains it ſometimes intermits, but rekindles with greater vigour and heat. Within three or four yards of it, he adds, there grows corn. The flame, he conjectures to ariſe from a vein of bitumen, or naphtha. There are three other ſuch fires on the ſame hills.

ERUPTIONS *in infants*. See INFANTS.

ERUPTIVE *fevers*. See FEVER.

ERVUM, *Bitter Vetch*, in *Botany*, a genus of the *diadelphia decandria* claſs: the characters of which are, that the empalement of the flower is divided into five equal parts, which end in acute points; the flower is of the butterfly kind, having a large, roundiſh, plain ſtandard, two obtuſe wings, of half the length of the ſtandard, and a ſhorter keel, which is pointed; it hath ten ſtamina, nine joined, and one ſeparate, terminated by ſingle ſummits. It hath an oblong germen, ſupporting a riſing ſtyle, crowned by an obtuſe ſtigma: the germen afterwards becomes an oblong, taper pod, jointed between each ſeed. There are ſix ſpecies.

ERVUM *orientale*. See SOPHORA.

ERYCINA, in *Mythology*, a ſurname given to Venus, from Erix a mountain in Sicily, where ſhe had a temple. Venus *Erycina* had alſo a temple at Rome, which was deemed very ancient, even in the time of Thucydides.

ERYNGO, or SEA-HOLLY, *Eryngium*, in *Botany*, a genus of the *pentandria digynia* claſs. Its characters are theſe: it hath many ſmall flowers, ſitting upon one common conical receptacle; the flowers have a five-leaved erect empalement, ſitting upon the germen, and form a roundiſh general umbel, which is uniform; each flower has five oblong petals, and five ſtamina, ſtanding above the flowers; under the empalement is ſituated a prickly germen, which afterward becomes an oval fruit divided into two parts, each having one oblong, taper ſeed.

There are ſeveral ſpecies of the *eryngium* plant propagated in the gardens of the curious; but the common ſea-kind is the only one of any uſe. The roots of this are, in great quantities, both dried and candied in the ſhops; they may all be propagated, either by parting their roots, or ſowing their ſeeds; but the firſt is the moſt convenient and expeditious method. This is to be done in autumn, when the leaves decay; and the ſoils they moſt delight in are gravel and ſand; but in dry ſeaſons they require a great deal of watering. The ſecond year after their removal from the old plant, they will flower, but the flowers are not ſo ſtrong as in the older plants. They ſpread very much at the root.

The true *eryngo* has creeping roots, which run deep into the ground; the leaves are roundiſh, ſtiff, and of a grey colour, ſet with ſharp ſpines on the edges; the ſtalks riſe a foot high, and divide upwards into two or three; they are ſmooth, and garniſhed at each joint with leaves of the ſame form as the lower, but ſmaller, and embrace the ſtalks with their baſe; at the end of the branches come out the flowers in roundiſh prickly heads; under each is ſituated a range of narrow, ſtiff, prickly leaves, ſpreading like the rays of a ſtar; the flowers are of a blue whitiſh colour; they appear in July, and the ſtalks decay in autumn.

The root of *eryngium* is attenuant and deobſtruent, and is therefore eſteemed a good hepatic, uterine, and nephritic. Its whole virtues, it is to be obſerved, conſiſts in the external or cortical part. The virtues, however, appear to be but weak; and they are now ſcarcely otherwiſe uſed than as made into a ſweetmeat.

The London College directs it to be candied in the following manner: boil the roots till the rind will eaſily peel off; when peeled, ſlice them through the middle, and the pith being taken out, waſh them three or four times in cold water; then for every pound of roots thus prepared, take two pounds of double refined ſugar; diſſolve the ſugar in water, ſet it on a fire, and as ſoon as it begins to boil, put in the roots, and continue the boiling till they become ſoft.

Theſe candied roots are an ingredient in artificial aſſes milk, which is thus made: take of candied *eryngo* root, one ounce; pearl barley, half an ounce; liquorice root, three drams; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil

boil them gently together, then ſtrain the liquor for uſe, of which half a pint ſhould be drank three times a day.

ERYNGIUM is alſo a name given by ſome of the old authors, to aloes; a medicine as different from the root of this name as any one thing can well be from another.

ERYNNIS, or FURIOUS, a name given to Ceres by the Sicilians.

ERYSIMUM. See *Hedge* MUSTARD.

ERYSIPELAS, ἐρυσίπελας, in *Medicine*, a diſeaſe of the ſkin, called alſo *ſacer ignis*, and *St. Anthony's fire*; and in many parts of Great Britain, the *roſe*.

In an ancient inſtrument belonging to the church of St. Antony at Marſeilles, this diſorder is called *ignis infernalis*, or *fire of hell*.

The word is formed of the Greek, ἕρυειν, *trahere*, *to draw*, and πέλας, *prope*, *near*; whence it is alſo called by the Latins *vicinitrahia*, and *vicinirubia*. Others derive it from ἐρυθρὸς, *red*, and αἷμα, *blood*, or *black*.

The ſanguine and plethoric, young people, and pregnant women are moſt ſubject to this diſorder.

Dr. Quincy accounts for the *eryſipelas*, from a too fiery blood, which, obſtructing the capillaries, occaſions inflammations; others, from a too ſharp and bilious blood, which, on account of its great fubtility, occaſions no ſenſible tumor, but ſpreads, or diffuſes itſelf, all around; and from the humours not being duly diſcharged by perſpiration. The colour of the tumor, though red, generally inclines towards a yellow, on account of the mixture of the bile; and always the more there is of the bile, the more dangerous the diſeaſe.

This diſorder may be occaſioned by any thing that overheats the blood, checks perſpiration, and obſtructs or diminiſhes either the natural or artificial evacuations.

In *eryſipelatous* fevers, which are juſtly ranked among the exanthematous kind, the blood and humours being in an immenſe motion, an acrid ſerum of the ſulphurous and cauſtic nature is, by that means, propelled to the ſurface of the body, and produces a ſwelling, accompanied with redneſs, heat, and pain.

This fever is far from being innocent and ſimple, as it is generally thought, and is often violent and dangerous, nay mortal, and, in ſome caſes, appears to be nearly allied to peſtilential fevers, the moſt formidable of all diſorders. The ſymptoms in both are of the ſame kind; and on the third or fourth day the morbid matter in both is thrown out to the ſurface, and the violence of the ſymptoms of this ſomewhat abates. But the great difference is, that the one is contagious, the other not ſo; and the peſtilential is much more fatal than the other uſually is found to be.

Phyſicians diſtinguiſh the *eryſipelas* into two kinds, the ſimple and the ſcorbutic. The ſimple or genuine *eryſipelas* affects only the ſurface of the body, and eaſily gives way to proper remedies, in a ſhort time; but the ſpurious, or ſcorbutic kind, is more deeply rooted, and hard to be removed; there is alſo a third kind, called an exulcerated *eryſipelas*, in which the eruptions are yellow, and contain an acrid pungent humour, which gives a terrible gnawing pain. This diſeaſe affects every part of the body, but particularly the legs and face, eſpecially the latter; and happens at all times of the year, but moſt frequently at the cloſe of ſummer. It ſometimes ſpreads over the whole face, and ſwells and inflames it in ſuch a manner as to endanger ſuffocation; being attended with an intenſe pain, and a number of little puſtules, which, as the inflammation increaſes, become veſicular. It often ſeizes people in a moment, while they are abroad, and is called by the country people a *blaſt*, or *ſideratio*; becauſe they imagine it proceeds from foul air, or ill wind; but it is generally occaſioned by cold caught after the body has been greatly heated or fatigued. It, in reality, differs very little from the effects of the ſtings of waſps and bees, except that the heats often riſe into puſtules. One kind of *eryſipelas* wholly reſembles the ſtinging of nettles; this is uſually brought on by drinking and is very troubleſome, the pimples appearing and diſappearing at times, ſometimes for a long while together.

Ermuller gives it as the diſtinguiſhing character of an *eryſipelas*, that when preſſed very lightly by the finger, there follows a white ſpot, which preſently after becomes red again, which does not happen in an ordinary inflammation, unleſs when violently preſſed. Scorbutic people are moſt ſubject to this diſeaſe. It is diſputed, whether purging be good in the *eryſipelas*? Sydenham recommends it the next day after bleeding. Ermuller cautions us againſt them both, and recommends diaphoretics. Dr. Freind obſerves, that in the laſt ſtage of an *eryſipelas* of the head, attended with a coma, delirium, &c. unleſs cathartics will do good, the caſe is deſperate. All unctuous, aſtringent, and cold applications, externally, are dangerous, and ſometimes make the *eryſipelas* degenerate into a gangrene.

However mild the more common kinds of this diſorder may naturally be, yet ill management will make even the ſlighteſt of them dangerous; and the ſtriking of the eruptions in has been often known to be of fatal conſequence. Hoffman mentions a patient he knew, who by taking a vomit, and a draſtic purge, in the time of the eruption, had an inflammation of the ſtomach brought on, and died in a few days. In many kinds of the *eryſipelas* nature does much, and with a little proper aſſiſtance, the whole terminates kindly in a ſhort time; but the bad kinds, nay, and too often the beſt, when treated unſkilfully, turn to violent burning fevers, and the eruptions to gangrenes.

The true method of curing *eryſipelas* conſiſts in three intentions: firſt, that the febrile motion of nature be by no means hindered, but rather promoted if it be found defective, and only reduced to a due temperament, if exceſſive. Secondly, that the ſubtile cauſtic matter be corrected and prepared for ſecretion and excretion; and thirdly, that the inflammatory ſtagnation of putrid and cauſtic lymph in the external parts be diſcuſſed, and perfectly expelled. Bleeding in an *eryſipelas* is ſometimes beneficial, ſometimes hurtful, and a good general rule is to order it in plethoric habits, and for perſons accuſtomed to drink ſpirituous liquors, and when the diſeaſe attacks the head, but to forbid it in others. In caſes where bleeding is neceſſary, the body ſhould be kept open by emollient clyſters, or ſmall doſes of nitre and rhubarb. When the inflammation is mild and gentle, it may ſometimes be removed by external warmth alone; but when it is more violent, it requires the help of internal, and ſometimes external remedies. Of the internal kind, the *mixtura ſimplex* is one ſtanding good medicine; and of the external, an ointment made of elder-bark, or the rob of elder, is known to have performed great cures; though ointments and plaſters tend rather to obſtruct and repel than to promote any diſcharge from the affected part. Fine wool, or ſoft flannel, are the fitteſt applications, which, by defending from the cold air, and promoting perſpiration, have a great tendency to remove the diſeaſe. Bathing the feet and legs in warm water is of conſiderable ſervice, when the diſorder has ſeized the face or brain; and if theſe fail, pultices, or ſharp ſinapiſms, applied to the ſoles of the feet, may be more effectual.

In the ſcorbutic *eryſipelas*, gentle laxatives will be proper, and ſuch things as purify the blood, and promote the perſpiration. When the inflammation has been checked by opening medicines, a decoction of ſarſaparilla root, ſhavings of guaiacum, ſaſſafras, and liquorice, may be drank, and ſucceeded by a courſe of bitters.

There is, beſide the common kinds of the *eryſipelas*, yet one more to be mentioned, which is always very terrible, and often fatal: this is an *eryſipelas* of the lungs. In this caſe the patient is ſeized with a highly burning fever, and an acute pain, both in the anterior and poſterior parts of the body, but eſpecially about the ſpine. He always holds his neck ſtraight upright when he breathes, and his noſtrils dilate with an exceſs of heat and pain, and, in the more advanced ſtages, his tongue hangs out of his mouth like that of a dog that pants with heat; ſweatineſs. He vomits ſometimes bile, and at other times phlegm, and is ſubject to very frequent faintings; the coughs much, and either ſpits not at all, or elſe a yellowiſh or bloody matter. This diſeaſe almoſt always proves mortal; and the only accident that can give the patient the leaſt hope, is its quitting the internal parts, and ſhewing itſelf on the ſurface.

Heiſter thinks, that the grand intention, in the curing of this diſorder, muſt be to dilute the inſpiſſated blood, and break and divide it where it ſtagnates, and is obſtructed. Plenty of thin and weak drinks are therefore to be adminiſtered, by which a gentle and laſting ſweat may be excited, and the teſtaceous powders, and nitrous medicines are frequently found alſo to have great and good effects. If the inflammation be but very ſlight, it is often cured by external warmth; but when warmth alone does not prove ſufficient, cloths, with the rob of elder, ſpread upon them, are found of great benefit, being laid warm on the part, and kept on by warm compreſſes, and the proper bandages. Ointments made of the middle green bark of elder, are alſo very beneficial; and notwithſtanding that many do not approve the practice, yet ſpirit of wine camphorated, with a mixture of ſaffron and Venice treacle, are found often of very great ſervice, applied warm, with coarſe paper or with linen rags; and a mixture of lime-water, and ſpirit of wine camphorated, often does great ſervice. It ſometimes happens, that an *eryſipelas* comes to ſuppuration; and from this generally ariſe the moſt untractable ſpreading and eating ulcers. In this caſe the ulcer is to be carefully cleanſed, and dreſſed with ointments of cerufs, red lead, or litharge, and plaſters of the ſame ingredients; and the patient

muſt, at the ſame time, take internal remedies to ſweeten the blood, ſome gentle purges, and obſerve a ſtrict regimen in regard to diet. Heiſter's ſurgery, p. 193.

If the black, livid, or blue colour of the eſchated part ſhews a tendency to mortification, the Peruvian bark may be given in the quantity of 3 dram every two hours, when the ſymptoms are threatening; and cloths dipped in warm camphorated ſpirits of wine, or the tincture of myrrh and aloes, or poultices of the bark, may be applied to the part, and often renewed; or it may be fomented with a ſtrong deco&ion of bark.

Thoſe who are ſubject to frequent attacks of the *eryſipelas* ſhould guard againſt violent paſſions, ſtrong liquors, and fat, viſcid, and highly nourihing food. They ſhould uſe ſufficient exerciſe, and avoid the extremes of heat and cold. Their food ſhould be chiefly milk and vegetables; and their drink ſmall beer, whey, butter-milk, &c. They ſhould prevent too long a ſtate of coſtiveneſs, either by ſuitable diet, or by often taking a gentle doſe of rhubarb, cream of tartar, lenitive electuary, or ſome other mild purgative. See Tiſſot's Advice, p. 288, &c. Buchan's Dom. Med. p. 276, &c.

ERYSIPELATOIDES, *from* ἐρυσίπελας, and εἶδος, *likeneſs*, in *Medicine*, is a ſwelling like that of the *eryſipelas*, though with eaſier ſymptoms; and therefore may be taken for a kind of *baſtard eryſipelas*; in this the ſkin is of a more dark colour.

ERYTHREAN, an appellation given to Hercules, from a temple which he had at Erythræ, in Arcadia.

ERYTHRÆAN *Sibyl*. See SIBYLS.

ERYTHREMA, a word uſed by the old writers in *Medicine*, to expreſs a redneſs of the cheeks, occaſioned by the violent heat in fevers. Some alſo have applied the ſame word, in the plural number, to the red inflammatory eruptions in an ERYSIPELAS.

ERYTHRINA, in *Botany*, a name given, by Linnæus, to a genus of ſuppoſed vegetables, called by Tournefort, Dillenius, and the generality of other writers, CORAL-LODENDRON, and CORAL.

ERYTHRINUS, in *Ichthyology*, the name of a fiſh, called by ſome authors alſo the *rutellus*, *trevalina*, and *alburn*, or *arburn*, by the Venetians. It is a ſmall fiſh, ſomething like the aurata, or gilt-head, in ſhape, but much ſmaller, and of a pale red colour all over. Its tail is forked, its noſe ſharp, and its eyes large, with ſilvery irides, and ſometimes a ſlight tinge of red amongſt the white. The mouth is ſmall, the fore-teeth broad, and the hinder ones are rather tubercles than teeth; the coverings of the gills are ſcaly. It has one back-fin, the anterior rays or nerves of which are prickly, the other ſoft and ſmooth to the touch. Rondelet. *de* Piſc. lib. v. cap. 13. p. 144

ERYTHROCTANEUS, in *Ornithology*, the red and blue macaw, with a wedge-like tail, and the ſides of the head naked and rough. See MACCAW.

ERYTHRODANUM, in the *Materia Medica*, a name by which ſome authors have called the rubia tinctorum, or MADDER.

ERYTHROIDES, in *Anatomy*, the firſt of the proper membranes that enclode the teſticles.

It is interſperſed with fleſhy fibres, derived to it from the cremaſter muſcle, which makes it appear reddiſh. And hence its name from ἐρυθρὸς, *red*, and εἶδος, *form*.

ERYTHRONIUM, in *Botany*. See DOG'S *Tooth*.

ERYTHROPHTHALMUS. See RED *Eye*.

ERYTHROXYLON, in *Botany*, a genus of the *decandria trigynia* claſs: the calyx is turbinated, the corolla has a fleſhy, nectariferous, enlargiated baſe, to which the ſtamina are joined; the fruit is a ſingle-celled drupe. Linnæus enumerates two ſpecies.

ERZ, or ERZI, in the botanical writings of the *Ancients*, a word uſed originally by the Hebrews, and by them made the name of the CEDAR.

ESAPHE, from ἐσάφαω, *I feel with the fingers*, a word uſed by Hippocrates, to expreſs the touching of the mouth of the uterus, in order to diſcover its ſtate or diſeaſes.

ESCALADE, or SCALADE, a furious attack of a wall or a rampart; carried on with LADDERS, to paſs the ditch, or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to ſecure the men.

When the troops are prepared to paſs the ditch, either with the aſſiſtance of boards, hurdles, and faſcines, when it is muddy, or with ſmall baſes of tin, or baſkets covered with ſkins, or oil-cloth, when it is deep, and filled with water, a party muſt be placed on the counter-ſcarp, oppoſite to the landing-place, ready to fire at the garriſon, if they are alarmed, and oppoſe the mounting on the rampart. If the ditch is dry, the ladders are fixed in ſome place fartheſt diſtant from the centry; and as ſoon as they get upon the rampart, they put themſelves in order to receive the enemy; if the centry ſhould be ſurpriſed, and ſilently overcome, the detachment haſtens to break open the gate, and to let in the reſt of the party.

If the ditch is wet, the rampart high, and provided with a reveſement, it will be difficult to ſurpriſe the town in this way; but if there is no reveſement, the troops may hide themſelves along the outſide of the rampart, till all are over. Since the invention and uſe of gun-powder, and the walls of cities have been flanked, they are ſeldom taken by *eſcalade*.

ESCALLION, in *Botany*. See SCALLION.

ESCAMBIO, from the Spaniſh *cambiar*, *to change*, was anciently a licence granted any one for the making a remittance, or giving a bill of exchange, to another beyond ſea.

For, by ſtat. 5 Rich. II. no perſon might exchange, or return money beyond ſea, without the king's licence.

ESCAPE, in *Law*, an evaſion out of ſome lawful reſtraint, either by violence or ſtealth.

Eſcapes are either *voluntary* or *negligent*.

Voluntary, as when one arreſts another for felony, or other crime, and afterwards lets him go, in which *eſcape*, the party that permits it, is, by law, to ſuffer puniſhment as if guilty of the fault committed by the perſon who *eſcapes*, be it felony, treaſon, or treſpaſs; after the original delinquent is actually found guilty or convicted.

Negligent eſcape is, when one is arreſted, and afterwards *eſcapes* againſt his will that arreſted him; and is not purſued by freſh ſuit, and taken again, before the party purſuing hath loſt ſight of him.

Keepers of priſons conniving at *eſcapes* ſhall forfeit 500*l.* and in civil caſes, the ſheriff is anſwerable for the debt.

ESCAPE *warrant*, in *Law*. If any perſon committed or charged in cuſtody in the king's bench or Fleet priſon in execution, or on meſne proceſs, &c. go at large; on oath thereof before a judge of the court where the action was brought, an *eſcape warrant* ſhall be granted, directed to all the ſheriffs, &c. throughout England, to retake the priſoner, and commit him to goal when taken, there to remain until the debt is ſatisfied; and a perſon may be taken on a Sunday upon an *eſcape warrant*. Stat. 1 Anne, cap. 6.

ESCAPEMENT, in *Horology*. See PALLET, and TIMEKEEPER.

ESCARTELE', in *Heraldry*, *quartered*, or QUARTERLY. See QUARTERING.

ESCH, in *Ichthyology*, a name given by Hildegard and others, to the fiſh we call the grayling, or umber, and the generality of authors, the thymallus. It is of the coregonous kind, and is diſtinguiſhed by Artedi by the upper jaw being longer, and the back fin containing twenty-three bones. The Germans call it *aſch*, and the Italians *temolo*.

ESCHALLOT, *Cepa Aſcalonica*, in *Botany*, a ſpecies of onion, cultivated in gardens for its uſe in cookery, and nearly reſembling the *Welch* ONION.

ESCHAR, in *Surgery*, a hard cruſt, or ſcab, formed on the fleſh, by means of a hot iron, or a cauſtic medicine, or ſome ſharp corroſive humour within.

The word ἔσχαρα ſignifies *cruſt*, or *ſcab*; which ſome authors derive from ἐσ and κάω, *I burn*; but this comes with ſome difficulty, becauſe κάω is written with a κ, and ἔσχαρα with a χ.

The cauſtic ſtone, or lapis infernalis, produces a round *eſchar* in the place where it has burnt. See ESCHAROTICS, CAUSTIC, and CAUTERY.

ESCHARA, in *Natural Hiſtory*, the name of a ſpecies of coralline, &c. the characters of which are theſe: they are of a ſtony, or coral-like hardneſs, and reſemble a woven cloth in their texture; and the microſcope ſhews us that they conſiſt of arrangements of very ſmall cells, whoſe ſurfaces appear much in that form. Linnæus makes it a ſpecies of *millepora*, in the claſs of lithophytes. See *Tab.* II. *Corallines*, *fig.* 9. and 10.

ESCHAROPEPA, a word uſed by the old writers in *Medicine*, to expreſs a coarſe kind of barley-meal, which had been torrified over the fire.

ESCHAROTICS, from ἔσχαρα, *eſchar*, medicines, which, being applied externally, produce *eſchars*, or ſcabs, by burning the fleſh. See ESCHAR.

Such are the lapis infernalis, red precipitate, &c. Theſe are alſo called *cauſtics*.

A compoſition of ſulphur, reſin, and honey, proves an *eſcharotic*, with little or no pain.

ESCHATON, in *Muſic*, the difference between the dieſis enharmonica and the hyperoche; that is, what remains, after taking the difference between the ſemi-tone minor and dieſis enharmonica, from the latter. Hendling, in Mic. Berolin. vol. i. p. 279, 280.

Thus the difference between the ſemi-tone minor and the enharmonic dieſis is $\frac{25}{24} : \frac{128}{125} = \frac{3125}{3072}$, and this taken from the dieſis, is $\frac{128}{125} - \frac{3125}{3072} = \frac{393216}{390625}$. This interval is about $\frac{53}{100}$ of a comma, as will eaſily appear by loga-

rithms. Mr. Henfling has taken notice of this interval. He calls it *eschasme*, from its being the leaft and the laft interval that occurs in his fyftem.
The word is Greek, σχασμα. See INTERVAL.

ESCHEAT, from the French *escheoir*, to happen, in *Law*, fignifies lands, or other profits, falling to a lord within his manor, either by way of forfeiture, or the death of his tenant dying without heir general or fpecial, or leaving his heir within age, and unmarried.
The civilians call fuch *efchaets*, or forfeitures, *bona vacantia*; and in the fame fenfe, as we fay the fee is *efcheated*, they fay *feudum operitur*.
The word *efchaeta* fometimes alfo fignifies a lawful inheritance defcending on the heir. But then it is ufually diftinguifhed by the addition of *recta*, as *recta efchaeta*.

ESCHEAT is alfo ufed for the place or circuit within which the king, or other lord, hath *efchaets* of his tenants.

ESCHEAT is alfo fometimes ufed for a writ, lying where the tenant having eftate of fee-fimple, in any lands or tenements holden of a fuperior lord, dies feifed without heir, general or fpecial: in which cafe the lord brings this writ againft him that poffeffes the lands, after the death of his tenant; and thereby recovers the fame in lieu of his fervices.

ESCHEATOR, an officer, who anciently took care of the king's efcheats in the county, and certified them into the exchequer, or chancery.
He was appointed by the lord treafurer; held his office only for one year; nor could any perfon be *efcheator* above once in three years. But this office, having its chief dependence on the court of wards, is now out of date.

ESCHEL, in *Mineralogy*, a term ufed by the fmalt-workers, to expreſs a fort of grey fubftance refembling aſhes, which is ufually mixed with the fmalt when in fuſion. This is carefully feparated from it, before it is powdered for ufe, otherwiſe it would debaſe the colour. Phil. Tranſ. N° 396.

ESCHEQUER. See EXCHEQUER.

ESCHEVIN, or ECHEVIN, *Echevins*, in the French and Dutch *Polity*, a magiſtrate elected by the inhabitants of a city, to take care of their common concerns; the good order, conveniency, and decoration of the city, &c.
At Paris, there is a prevot, and four *eſchevins*; in moſt other cities, a maire, or mayor, and *eſchevins*. In Languedoc, Provence, and Dauphiné, they are called *conſuls*; at Touloufe, *capitouls*; and *jurats* at Bourdeaux.
Anciently, the *eſchevins* were the aſſeſſors, and counſellors of the comites, or judges of cities; on which account they were called, in ſome places, *pairs*, *pares*; they even took cognizance of petty cauſes themſelves.
Du-Cange obſerves, that the judges, and their aſſeſſors, who were choſen by the inhabitants, were called *ſcabini*, *eſchevini*, and their college, *ſcabinogium*, or *eſchevinage*. He adds, that ſome authors call them *pacierii*, becauſe their office and juriſdiction extended to the ſecuring peace in their city and banlieue, called *jour villæ*.
In Holland, the *ſcabini*, or *eſchevins*, judge of all civil affairs at firſt hand. They alſo take cognizance of criminal matters; and if the criminal confeſs himſelf guilty, they can fee their ſentence executed without appeal. They can even give torture. The number is not the ſame in all cities; at Amſterdam there are nine, at Rotterdam ſeven, &c.

ESCHRAKITES, or ESRAKITES, a ſect of philoſophers, among the Mahometans, who adhere to the doctrines and opinions of Plato.
The word is derived from the Arabic שרק, *ſchraka*, which in the fourth conjugation אשרק, *aſchraka*, ſignifies *to ſhine*, *glitter like the ſun*; ſo that *Eſchrakite* ſeems to import *illuminati*.
The *Eſchrakites*, or Mahometan Platoniſts, place their higheſt good and happineſs in the contemplation of the Divine Majeſty; deſpiſing the groſs imaginations of the Alcoran touching paradiſe. See MAHOMETANISM.
They are very careful in avoiding all vice; they preſerve an equal and eaſy temper, love muſic, and divert themſelves with compoſing little poems, or ſpiritual ſongs. The ſheiks, or prieſts, and the chief among the preachers of the imperial moſques, are *Eſchrakites*.

ESCHYNOMENOUS *plants*. See ÆSCHYNOMENOUS.

ESCLAIRCISSEMENT, a French term, which we find retained in ſome late Engliſh writers: it properly ſignifies the act, or effect, of clearing a thing, or rendering it more bright and tranſparent; being formed from the verb *eſclaircir*, *to clear*, &c.
It is chiefly uſed in a figurative ſenſe, for an explanation of an obſcurity or difficulty. The *eſclairciſſement* of difficult paſſages in the Bible, is to be ſought for from ſimilar paſſages, or paſſages of the like kind occurring in other places.

ESCLAME, in the *Manege*, an obſolete French word, formerly uſed to ſignify a light-bellied horſe.

ESCLATTE', in *Heraldry*, is applied to a thing violently broken. Thus a bend, or rather partition, *eſclatté*, is repreſented torn, or broken off, like a ſhield ſhattered with the ſtroke of a battle-ax.

ESCORT, a French term, ſometimes uſed in Engliſh authors to denote a convoy, or company of armed men, attending ſome perſon or thing, in a journey or voyage, to defend or ſecure it from inſults.
Some derive the word from the Latin *cohors*. See CONVOY.

ESCOUADE, or SQUAD, is uſually the third or fourth part of a company of foot; ſo divided for mounting guards, and for the more convenient relieving of one another. It is equivalent to a brigade of a troop of horſe. See BRIGADE.

ESCROL, or SCROLL, in *Heraldry*, a long ſlip, as it were, of parchment, or paper, wherein a motto is placed.
Leigh obſerves, that no perſon, under the degree of a knight, might, long after king Henry V. place his creſt on a wreath, as is now uſually done, but only on an *eſcrol*.

ESCROW, a deed delivered to a third perſon, to be the deed of the party making it, upon a future condition; when ſuch thing is performed; and then it is to be delivered to the party to whom made. It is to be delivered to a ſtranger, mentioning the condition; and has relation to the firſt delivery. 2 Roll. Abr. 25, 26. 1 Inſt. 31. See DEED.

ESCU, or ECU, the French crown, of ſixty ſols, or three livres. The *eſcu* was thus called, becauſe the eſcutcheon, or arms of France, which they call *eſcu*, was ſtruck thereon. See COIN.

*Emaux de l'*ESCU. See EMAUX.

ESCUAGE, or SCUTAGE, an ancient kind of knight's ſervice, called alſo *ſervice of the ſhield*; the tenant holding by which, was obliged to follow his lord to the Scottiſh or Welch wars, at his own expence. But perſonal attendance being inconvenient, the tenants compounded for it by a pecuniary ſatisfaction, which was levied by aſſeſſments at a certain rate for every knight's fee; and thus it became a pecuniary, in lieu of a military ſervice.
The firſt inſtance that occurs was in 5 Hen. II. on account of his expedition to Touloufe; it afterwards became more general and oppreſſive; ſo that king John was obliged to conſent, by his Magna Charta, that no *ſcutage* ſhould be impoſed without conſent of parliament; but the clauſe was omitted in the charter of Hen. III, which directs, that it ſhould be taken as it uſed to be in the time of Henry II. or in a reaſonable and moderate manner. However, it was afterwards enacted by ſtat. 25 *Edw.* I. cap. 5 and 6. and many ſubſequent ſtatutes, that the king ſhould take no aids or talks, but by the common aſſent of the realm; and it appears that *ſcutages* were the ground-work of all ſucceeding ſubſidies, and of the land-tax of later times. Blackſt. Com. vol. ii. p. 74.

ESCUAGE was alſo a reaſonable aid, demanded by the lord of his tenants, who held of him by knight's ſervice. See AID.
Conceſſerunt domino regi ad maritandum filiam ſuam de omnibus qui tenent de domino rege in capite de ſingulis ſcutis 20 ſolidos ſolvendos. Matt. Paris. anno 1242.

ESCULAPIUS, in *Mythology*, the god of medicine. He was the ſon of Apollo, by the nymph Coronis, born at Epidaurus, where he had a famous temple, in which his image, made of gold and ivory, was placed on a throne of the ſame materials; it was crowned with rays, had a knotty ſtick in one hand, and the other was laid upon a ſerpent, and a dog lay at his feet. The Epidaurians inſtituted ſolemn games, which were celebrated in honour of him once every five years. This god was brought to Rome, by order of Apollo, when a peſtilence raged in that city, in the times of the republic, and was honoured as one of the chief of their made-gods. He is ſaid to have ſtolen away from his old worſhippers under the ſhape of a ſerpent. He is repreſented with a mild look, and with hair and beard not unlike thoſe of the mild Jupiter; his right arm is bare, in order to denote his readineſs for any operation; his left holds a ſtick, with a ſerpent twiſted round it. The dog and cock have been reputed ſacred to this deity, on account of their vigilance, and the raven for his foreſight. Statius, lib. iii. Sylv. 4. ver. 25. Ovid. Met. xv. ver. 662.

ESCULENTS, from *eſculentus*, *eatable*, a term uſually applied to vegetables which are fit for food, as artichokes, carrots, turneps, parſneps, cabbages, cauliflowers, &c.

ESCULUS, in *Botany*, a name given, by many authors, to the phagus, or ſweet oak, called alſo the eſculent oak.

ESCULUS, or ÆSCULUS. See *Horſe* CHESTNUT.

ESCURIAL, by the Spaniards written ESCORIAL, a term that occurs pretty frequently in our gazettes, and newspapers, for a place of reſidence of the kings of Spain.
Eſcurial originally denotes a little village in Spain, ſituate in the kingdom of Toledo, ſeven leagues to the weſt of

Madrid, and nine to the eaſt of Avila, on the ſide of a chain of mountains, called by ſome the Carpetani, or Carpentanian mountains, and by others the Pyrenean, as being the branch of the Pyrenean ridge. Here king Philip II. built a ſtately monaſtery of the order of St. Jerom, held by the Spaniards for one of the wonders of the world, and called the *Eſcurial*. It was begun in 1557, and finiſhed in about twenty-two years.

Fr. Franciſco de los Padros, in a deſcription thereof, intitled, Deſcription breve del Monaſterio de S. Lorenzo el real del Eſcorial, &c. aſſures us it was built by that prince in memory of the battle of St. Quintin, gained on the day of St. Laurence, Lorenzo, a famous Spaniſh ſaint, and at his interceſſion; accordingly the plan of the work reſembles a gridiron, the inſtrument of the ſaint's martyrdom.

The king and queen have their apartments there; the reſt being poſſeſſed by the monks. Whence many of the great tranſactions of that court are dated from the *Eſcurial*.

The *Eſcurial* has a very fine church, to which Philip IV. built a beautiful chapel, called the Pantheon, or Rotonda, wherein the kings and queens of Spain, who leave any poſterity, are interred; the reſt being laid in another vault of the ſame church, together with the infantas, and other princes.

It has eleven thouſand windows, fourteen thouſand doors, one thouſand eight hundred pillars, ſeventeen cloiſters or piazzas, and twenty-two courts; with every convenience and ornament that can render a place agreeable in ſo hot a climate; ſuch as an extenſive park, groves, fountains, caſcades, grottos, &c. This palace contains three libraries, in which are eighteen thouſand volumes, and three thouſand Arabian manuſcripts. Part of this ſuperb palace was burnt in 1671.

ESCUTCHEON, or SCUTCHEON, in *Heraldry*, the field, or coat, wherein the bearing, or arms, of any perſon, are repreſented.

The word *eſcutcheon* is formed of the French *eſcuſſon*, and that from the Latin *ſcutum*, *ſhield*; which was the place arms were originally born on, before ever they came on banners; and ſtill, wherever they are placed, it is on ſomething repreſenting the form of a ſhield. The Latin *ſcutum*, no doubt, came originally from the Greek, σκυτος, *leather*, wherewith the ſhields were uſually covered. See SHIELD.

The *eſcutcheon* is of a ſquare figure, excepting the bottom part, which is uſually a little rounded, ending in a point in the middle. See *Tab. Heraldr. fig.* 38.

Till within a few hundred years, the *eſcutcheons* of the French and Engliſh were triangular: thoſe of the Spaniards are ſtill quite round at bottom, without any point; thoſe of the Italians are oval; and thoſe of the Germans in form of cartouzes.

The ancient *eſcutcheons* were generally couched, or inclined; and they only began to place them upright, when crowns, &c. were put over them by way of creſt.

In France, *eſcuſſon*, *eſcutcheon*, was formerly reſtrained to a ſhield, or coat, pointed at bottom; by which it was diſtinguiſhed from the *eſcu*, which was quite ſquare, and was only allowed to be borne by the counts and viſcounts. Thoſe of the inferior quality were confined to the eſcuſſon or pointed eſcu.

The ſeveral parts or points of the *eſcutcheon* have their proper names: the point A, for inſtance, is the *dexter point*; B the *middle chief*; and C the *ſiniſter chief point*; D is the *honour point*; E the *teſſe point*; F the *nombril point*; G the *dexter baſe*; H the *middle*; and I the *ſiniſter baſe* point.

The *dexter ſide* of the *eſcutcheon* anſwers to the left hand, and the *ſiniſter ſide* to the right hand of the perſon that looks on it.

The *eſcutcheon* is differently denominated, according to its diviſions. It is called *dexterol*, when the perpendicular line that divides it, is to the right of a third part of the *eſcutcheon*; *ſiniſtered*, when on the left; *tierced in pale*, when this line is double, and divides the whole *eſcutcheon* into three equal parts; *paled*, when increaſed to the number of ſix, eight, or ten. A horizontal line makes the *chief*, when at one third part from the top; the *plein*, when at a third from the bottom; and when double, in the middle, at an equal diſtance from both extremes, it makes the *teſſe*, and the *tierced in teſſe*; when it is multiplied, it denominates it *teſſed*; when there are eight or ten equal ſpaces, *barrells*. A diagonal from the dexter point of the chief to the ſiniſter of the baſe, makes it *tranché*: the contrary, *douſil*; if it be doubled at equal diſtances, the firſt makes *bandé*, and the *tierce in bend*; and the other *barré*, *or tierce in bar*; increaſing the number of the firſt makes *bandi*, and *cottici*; and increaſing that of the ſecond *barri*, and *traverſe*.

ESCUTCHEON *of pretence*, is an *eſcutcheon*, or little *eſcutcheon*, which a man, who has married an heireſs, and has iſſue by her, may bear over his own coat of arms; and in it the arms of his wife; and, in this caſe, the ſurviving iſſue will bear both coats quarterly. See *Tab.* II. *Heraldry, fig.* 64.

ESCUTCHEON, in *Sea-language*, a name ſometimes given to the compartment for the names or arms of the owner, or of the perſon whoſe title the veſſel aſſumes. It is uſually fixed on the middle of the ſhip's ſtern; and is more peculiar to the French, and other foreigners, than to Engliſh-built veſſels. Falconer.

ESCUTCHEON-*graffing*, in *Gardening*. See ENGRAFTING.

ESDRAS. See EZRA.

ESEBON, a name given, by ſome of the chemical writers, to common ſea-ſalt.

ESNECY, *Jus natus*, *Eſnitus primogenitus*, in *Law*, a private prerogative, allowed to the eldeſt *coparcener*, where an eſtate is deſcended to daughters for want of heirs male, to chuſe firſt after the inheritance is divided. Flets lib. 2. cap. 10. *Jus eſnecie is jus primogenituræ*; in which ſenſe it may be extended to the eldeſt ſon, and his iſſue, holding firſt. In the ſtatute of Marlbridge, cap. 9. it is called *mitius jure hereditatis*.

ESOTERIC, in *Antiquity*. See EXOTERIC.

ESOX, in *Ichthyology*, the name of a genus of fiſhes, of the claſs of abdominales, in the Linnæan ſyſtem; the characters of which are theſe: they are of the malacopterygious, or ſoft-finned kind. The branchioſtege membrane contains from ſeven to twelve bones. The body is oblong; the back-fin not large, and is placed very near the tail. The ſpecies of this genus, enumerated by Artedi, are three, and by Linnæus nine.

The word *eſox* is truly Roman. Pliny, and other of the ancient Latin authors, have uſed it as the name of the ſame fiſh. It ſeems to have been derived from the verb *eſſe*, *to eat*; for all the ſpecies of this fiſh are very voracious.

ESPALIER, in the *French Gardening*, a wall-tree; or a fruit-tree, which is not left to grow at liberty in full air, but has its branches nailed, or faſtened, to a wall, or ſome other flat ſurface, near which it is planted; and, thus growing, it is made to conform itſelf to the flat, though unnatural, figure thereof. See FRUIT-*Tree*, WALL, &c.

ESPALIERS, in our *Gardening*, are rows of trees, planted regularly round the outſide of a garden, or plantation, for the general ſecurity thereof from the violence and injury of the winds; or elſe only round ſome part of a garden, for the particular ſecurity of a plantation of orange-trees, lemon-trees, myrtles, or other tender plants; or, laſtly, for the bounding of borders, walks, avenues, &c.

Eſpaliers are now come into great uſe, with reſpect to the firſt of theſe intentions: in effect, it is found by experience, that the beſt brick, or ſtone walls, are not of themſelves ſufficient ſecurity to fruit-trees, from the ravages of blighting winds.

The reaſon may be, that, being built cloſe and compact, they repel the winds, and, by that means, damage the tender plants, that lie within the reach of the repulſion; but theſe *eſpaliers* ſerve to deaden the violence of the winds, ſo that the tender greens, or plants, encompaſſed by them, reſt ſerene and quiet.

Thus, if the *eſpaliers*, for inſtance, be of ſpruce, fir, holly, or yew, they give way to the force of tempeſtuous winds beating againſt them, without occaſioning any reflition thereof. Meſſ. London and Wiſe direct them to be planted at ſome diſtance, without the outmoſt bounds or walls of gardens, &c. Two or three rows of trees they think ſufficient, from eighteen or twenty to twenty-five feet apart; and as to the method, or order, of diſpoſing the trees, the moſt commodious is, where the middle row makes every where equilateral triangles with the extreme rows, in the following manner. See QUINCUNX.

* * * * * *
* * * * * *
* * * * * *

The trees recommended for making, or planting, theſe *eſpaliers* fences, are, the elm, lime, beech, Scotch fir, oak, pine, and ſycamore; but, particularly, the two firſt. *Eſpaliers* are moſt commonly made of fruit-trees trained up to a lattice of wood-work, formed either out of aſh-poles, or ſquare pieces of fir-wood; and their moſt uſual office is the ſheltering, and at the ſame time hiding the quarters of kitchen gardens.

The trees principally planted for *eſpaliers* now, are apples and pears, and ſome plums. The apples intended for *eſpaliers* ſhould be grafted on crab-ſtocks, for large gardens, and for ſmaller on codling-ſtocks. The trees for the ſame hedge in an *eſpalier*, ſhould be all ſuch as are of he ſame age, from the grafting, and produced from the ſame ſtocks, that ſo the hedge may be the more regular. The more quick growing and ſpreading ones, muſt be planted at thirty or thirty-five feet aſunder, and thoſe of

ſmaller

smaller growth, at twenty-five feet; the walk between them in a large garden should be fixteen feet wide; and if the *espaliers* are intended to be carried up high, it should be more, that both hedges may have the benefit of the fun.

The beft forts of apples for *eſpaliers*, are the golden pippins, the nonpareil, the rennet griſe, the aromatic pippin, the Holland pippin, the French pippin, Wheeler's ruſſet, and Pitt's ruſſet; for the choice and pruning of theſe trees, ſee APPLES and PRUNING.

The pears, fitteſt for *eſpaliers*, are the ſummer and autumn kind; for the winter ones ſeldom ſucceed well. Theſe trees, if deſigned for a ſtrong moiſt ſoil, ſhould be on quince ſtocks; but if for a dry ſoil, upon free ſtocks. The diſtance for pears grafted on free ſtocks ſhould be thirty feet, for moderately growing trees, and for the moſt vigorous ſhooters, it ought to be, at leaſt, forty feet. And the beſt kinds of pears for this purpoſe, are the jargonelle, the blunquette, the poire ſans peau, the ſummer bonecretien, Hamden's burgamot, the poire du prince, autumn burgamot, Pambrette, gros rouſſelet, chaumontelle, beurre de roy, the le marquis, and the creſſane.

The third year after the trees are planted, the frame-work of the *eſpalier* ſhould be made. Till this time the young ſhoots need only be trained to upright ſtakes, as nearly as can be in an horizontal direction. The beſt way of making the wood-work is of aſh-poles, which are not only cheap, but ſtrong and durable. Theſe are of two kinds; the largeſt poles, deſigned for upright ſtakes, ſhould be cut about ſeven feet and a half long, and placed at a foot diſtance, in a right line, and about ſix feet above the ground, at the ſame height, a row of ſtraight ſlender poles ſhould be nailed along the tops of the upright ſtakes, in order to keep them even, and the ſtakes ſhould be croſſed with the ſmaller poles, at about nine inches diſtance, row from row, from the top to the bottom, and theſe rows of poles ſhould be well faſtened to the ſtakes with wire. Then the branches of the fruit-trees are all to be trained horizontally to theſe, and none ſhould be ſuffered to croſs one another, nor come too near, and faſtened to them with ſmall oſier twigs, or rope-yarn. In the trees which produce large fruit, no branches ought to be nearer to each other than ſix or eight inches; in the ſmaller fruited ones, four or five inches will be ſufficient; the advantages of the trees planted in *eſpaliers*, above thoſe propagated as dwarfs, in the room of which theſe have been introduced, are many and very great. They take up very little room in a garden, and are of no injury to the plants cultivated in the quarters; and the fruit is always more regularly ripened and better taſted, as the ſun and air can have every way free acceſs to it. Miller.

To prevent the diſorders that may befall *eſpalier* fruit-trees, when in bloſſom, Mr. Bradley mentions a nurſery-man, who, having moſt ſorts of fruit in *eſpaliers*, had portable hedges made of reeds in frames, which he ſet both at the back and front of his *eſpaliers*, as he ſaw occaſion.

ESPAULE, ESPAULEMENT, &c. in *Fortification*. See ESPAULE, ESPAULEMENT, &c.

ESPHILASIS, from ἐσφάλωσις, *to recede inwards*, a term uſed by the old writers in *Medicine*, for the receding inward of the ſkull in depreſſions from contuſions.

ESPLANADE, in *Fortification*, called alſo GLACIS; a part which ſerves the counterſcarp, or covert way, for a parapet; being a declivity, or ſlope of earth, commencing from the top of the counterſcarp, and loſing itſelf, inſenſibly, in the level of the champagne.

ESPLANADE alſo ſignifies the ground which has been levelled from the glacis of the counterſcarp, to the firſt houſes; or the vacant ſpace between the works and the houſes of the town.

The term is alſo applied, in the general, to any piece of ground which is rendered flat, or level, and which before had ſome eminence that incommoded the place.

ESPLEES, *Expletia*, from *explere*, in *Law*, the products which ground or land, &c. yield; as the hay of the meadows, the herbage of the paſture, corn of the arable, rents, ſervices, &c. and of an advowſon, the taking of tithes in groſs by the parſon; of wood, the felling of wood; of an orchard, the fruit growing there; of a mill, the taking of toll, &c. Theſe and ſuch like iſſues are termed *eſplees*. And it is obſerved, that in a writ of right of land, advowſon, &c. the demandants ought to allege in his count, that he or his anceſtors took the *eſplees* of the thing in demand; otherwiſe the pleading will not be good.

Sometimes this word hath been applied to the farm, or land, &c. themſelves.—*Dominus E. habebit omnia* expletias *& profectus de earum emergentia.* Plac. Parl. 30 Edw. I.

ESPOUSALS, *Sponſalia*, in *Law*, a contract or mutual promiſe between a man and a woman to marry each other. Marriage or matrimony is ſaid to be an *eſpouſal de preſenti*.

ESQUADRILLE. See QUADRILLE.

ESQUADRON. See SQUADRON.

ESQUIAVINE, in the *Manege*, an old French word ſignifying a long and ſevere chaſtiſement of a horſe in training him.

ESQUINANCY, in *Medicine*, a diſeaſe called alſo *angina*, *ſquinancy*, and, popularly, QUINZY.

ESQUIRE, a title of diſtinction, next below that of knight, and above that of a ſimple gentleman.

The origin, both of the name, and the thing, *eſquire*, is very obſcure. The Engliſh denomination is confeſſedly borrowed from the French, *eſcuyer*; and that from the Latin *ſcutum*, *ſhield*, as ſome will have it; or, as others, from *ſcutarius*, *or ſcutifer*, *ſhield-bearer*; or from *ſcuria*, *ſtables*; or from *equis*, *groom*. So many different opinions of the formation of the word, have given riſe to as many about the primitive office of *eſquires*; unleſs, perhaps, the latter hath given occaſion to the former. Paſquier, in his Recherches, liv. ii. chap. 15. maintains the title of *eſquire*, *eſcuyer*. *ſcutarius*, to be very ancient. From the time of the declenſion of the Roman empire, he obſerves, there were two extraordinary kinds of ſoldiery in the Roman army: the one called *gentiles*, and the other *ſcutarii*.

Ammian. Marcellin. lib. xiv. cap. 7. and lib. xvi. cap. 4. ſpeaks of theſe *ſcutarii* as men of redoubted proweſs, and even deemed invincible: it is added, that Julian the Apoſtate fet a mighty value on thoſe troops, when he was among the Gauls; and hence, probably, it was, that the Gauls, or, perhaps, only the Franks, finding the braveſt among the Roman forces were called *gentiles*, and *ſcutarii*, gave the like names to the boldeſt and braveſt among themſelves; ſuch, according to that curious antiquary, is the original of *eſquire*.

Eſquire, however, afterwards came to be uſed in a ſomewhat different ſenſe; viz. for a gentleman who attended a knight in the wars, and on other military occaſions; bearing his ſhield, *ſcutum*, before him (whence he was called *ſcutarius*, *ſcutiger*, or *ſcutifer*), as alſo his lance, and other weapons; whence his other Latin appellation, uſual among us, *armiger*, q. d. *armour-bearer*. And hence, likewiſe, it is, that, in all our ancient romances, the hero is conſtantly attended by a gentle and truſty *ſquire*.

After all, the moſt probable derivation of *eſcuyer* is not from *ejcu*, *ſcutum*, as is the common opinion; but from *equus*, *horſe*; the primitive *eſquires* being no other than what the Latins call *equiſones*, who had the care and intendance of the equerries, or ſtables, only.

Be this as it will, the title *eſquire*, *armiger*, as now eſtabliſhed among us, is next below that of knight, *eques*. They who bear this title are all younger ſons of noblemen, and the eldeſt ſons of ſuch younger ſons; the eldeſt ſons of knights, and their eldeſt ſons ſucceſſively: both which ſpecies of *eſquires* Sir Henry Spelman entitles *armigeri notabiles*, the four *eſquires* of the king's body, and *eſquires* created by the king, by putting about their necks a collar of SS's, and beſtowing on them a pair of ſilver ſpurs, letters patent, or other inveſtiture, and their eldeſt ſons. Laſtly, divers others, in the ſuperior public offices, are reputed *eſquires*, or equal to *eſquires*, as ſheriffs of counties, ſerjeants at law, juſtices of peace, mayors of towns, counſellors at law, lieutenants, colonels, majors, captains, &c. during the time of their commiſſion. Laſtly, the heads of ſome ancient families are likewiſe *eſquires* by preſcription. To theſe muſt be added the *eſquires* of knights of the Bath, each of whom conſtitutes three at his inſtallation; and all foreign, nay Iriſh peers; for not only theſe, but the eldeſt ſons of peers of Great Britain, though frequently titular lords, are only *eſquires* by the law, and muſt be ſo named in all legal proceedings. See GENTLEMAN.

ESQUISSE, in the French *Painting*, a term ſignifying the firſt light ſketch or draught of a picture; the firſt thought of a deſign drawn haſtily with a crayon, or in colours, on paper, canvas, or the like, in order to be finiſhed, and painted, or engraven afterwards.

He had not the trouble of making a finiſhed and correct deſign, but went to work upon the *eſquiſſe*.

The word is formed of the Italian *ſchizzo*, a *ſplaſh*; becauſe an *eſquiſſe* of a painting only repreſents, as it were, ſplaſhes, or dabs, of colours.

ESRAKITES. See ESCHRAKITES.

ESSÆANS. See ESSENI.

ESSART, or ASSART. See ASSART.

Du-Cange derives the word from ſome of the barbarous Latin words, *exartare*, *exartuſſe*, *eſſortum*, *eſſartum*, *ſartum*, and *ſartus*; which all ſignify a foreſt cut down, or dug up; though Spelman chooſes to deduce it from the Latin *exertum*, *turn up*, or *uncreted*. Others from *ſarire*, *to weed*;

wood; and others, laſtly, from *exare*, *I plow*; whence *exartare*: and, by contraction, *exartum*. In our ancient law-books, *exartum facere in ſylva*, is to *aſſart* a place in a foreſt. To *aſſart*, is to grub up, or extirpate, buſhes, trees, old roots, ſtumps, or the like; in order to fit the ground for tillage.

ESSATUM, a word uſed by ſome of the chemical writers, to expreſs the medicinal power or ſanative property reſiding in ſimple medicines.

ESSAY, a trial, or experiment, to prove whether a thing be of the requiſite quality or goodneſs.

The word is French, *eſſai*; which ſome authors derive farther from the Latin *examen*.

ESSAY is alſo uſed for an attempt, or tentative, to learn whether or no a thing will ſucceed.

Eſſays of machines ſhould be made in large; it is not enough that they ſucceed in little.

ESSAY, in *Monaſteries*, is particularly uſed for a trial which a perſon makes of the monaſtic life, in a ſecular habit.

This *eſſay* is of one, two, and, in ſome monaſteries, of three months. The *eſſay* is not reckoned in the novitiate. See PROBATION.

ESSAY, or ASSAY, or ſimple SAT, in *Cookery*. See ASSAY.

ESSAY, in matters of learning, is a peculiar kind of compoſition; whoſe character is to be free, eaſy, and natural; not tied to ſtrict order, or method, nor worked up, and finiſhed, like a formal ſyſtem.

The matter of an *eſſay* is ſuppoſed to conſiſt principally of ſudden and occaſional reflections, which are to be wrote much at the rate, and in the manner, a man thinks; ſometimes leaving the ſubject, and then returning again, as the thoughts happen to ariſe in the mind.

At leaſt, this has hitherto been the practice; and Montagne, who has acquired no ſmall reputation by this way of writing, ſeldom keeps many lines to the ſubject he propoſes; though it is our opinion, that lord Bacon, in many of his works, is a better pattern in the *eſſay* kind. Mr. Locke, however, and a few other authors, uſe *eſſay* in a ſeverer ſenſe: the Eſſay of Human *Underſtanding*, every body knows, is a regular, artful, and laboured work; though perhaps ſo called, to guard againſt too ſevere ſtrictures, by pleading the title.

ESSAY-*bank*, is the miners term for a little trench or hole, which they dig to ſearch for *ſtone*, or ore. See TIN.

ESSAY-*maſter*. See MINT, and ASSAY.

ESSE, in the *School Philoſophy*, is uſed in the ſame ſenſe with eſſence; principally for that which is actual, or actually exiſting.

The word is pure Latin; being the infinitive of the verb *ſum*, *I am*; whence *eſſe*, *to be*.

From *eſſe* ariſes *eſſeum*, a barbarous term, now almoſt obſolete, ſignifying that which is endued with eſſence, or nature; or ſuccted with the virtue, or efficacy, of another. Some diſtinguiſh *eſſe* into *reale* and *intentionale*; and, again, into *eſſentiale* and *eſſeum*.

ESSEDARIUS, among the Romans, a gladiator, who fought in a car, or chariot. See Hiſt. Acad. Inſcript. vol. 6 p. 376, ſeq.

ESSENCE, that which conſtitutes, or determines, the nature of a thing; or which is abſolutely neceſſary to its being what it is. This Mr. Locke calls the nominal *eſſence*, in contradiſtinction to the real *eſſence* or conſtitution of ſubſtances, on which this nominal *eſſence* depends: thus, the nominal *eſſence* of gold, is that complex idea which the word gold repreſents; e. gr. a body, yellow, heavy, malleable, fuſible, and fixed: but its real *eſſence* is the conſtitution of its inſenſible parts, on which thoſe qualities, and all its other properties depend; which is wholly unknown to us.

In philoſophy, the *eſſence* of a thing is defined to be, that whereby a thing is diſtinguiſhed from every other thing. The Cartheſians hold the *eſſence of matter* to conſiſt in extenſion; and, on that principle, deny that there is any ſuch thing as mere ſpace, or vacuity: but the hypotheſis is falſe, as is ſhewn under the articles MATTER, SPACE, VACUITY, PLENUM, &c.

Gaſſendus, and moſt of the corpuſcular philoſophers, hold the *eſſence* of matter to conſiſt in ſolidity, or impenetrability, reſiſtance, or, more adequately, in a ſolid impenetrability reſiſting the touch; which it muſt be allowed, of all the properties of matter, ſeems to have the faireſt title to it.

The ſchool philoſophers give us two ſignifications of the word *eſſence*: the firſt denotes the whole eſſential perfection of a being, and, conſequently, its entity, with all its intrinſic, or eſſential, and neceſſary attributes, taken together: in which ſenſe, *eſſence* may be defined to be, all that whereby a thing is, and what it is. In which caſe the *eſſence* of a thing is to the thing itſelf, what humanity, *e. g.* is to man.

The ſecond ſignification of *eſſence* is, that whereby it denotes the principal, and moſt intimate, of all the attributes of a thing; or that which agrees to every ſuch thing, and ſuch alone, and that always, and in ſuch manner, as that the mind, with all its attention, cannot perceive any thing prior thereto; by which, *eſſence* is diſtinguiſhed from the eſſential attributes, i. e. from ſuch as flow from its *eſſence*, or firſt attribute. Thus, the *eſſence* of the human mind is commonly ſuppoſed to conſiſt in the power of thinking; becauſe all its other perfections ſeem to pre-ſuppoſe this; but this pre-ſuppoſes none. And thus the powers of underſtanding, doubting, aſſenting, willing, &c. do all flow from the power of thinking; and cannot exiſt without it, though this may without any of them.

It muſt be allowed, however, that the eſſential properties of a thing do ſo cloſely cohere, nay, and inhere, in the *eſſence* itſelf, that it is ſcarce poſſible to diſtinguiſh the one from the other. Hence, what ſome urge, that, letting aſide all the attributes and properties of a thing, and what remains is its *eſſence*, is a mere chimera. For let aſide, e. gr. from the mind, the powers of underſtanding and willing, with the reſt of its attributes, and what will there remain to call its *eſſence*?

It is greatly diſputed, in the ſchools, whether the *eſſences* of created things be eternal? or whether the *eſſences*, as well as the exiſtences, had their origin in time? The Cartheſians hold, that the *eſſences* of things depend abſolutely on the free concurring will of God.

ESSENCE, in *Medicine* and *Chemiſtry*, denotes the pureſt, moſt ſubtil, and balſamic part of a body, extracted from the reſt by means of fire.

Of theſe there is a great variety, drawn from flowers, fruits, and the like, uſed on account of their agreeable ſmells, and taſtes, by the apothecaries, perfumers, &c. The principal are, *eſſence* of roſemary; of turpentine; of anile; of cloves; of cinnamon; and of citron.

The *eſſences* commonly ſold by the perfumers, are only the diſtilled oils of behn, and of bitter almonds; to which they give the ſmell of certain flowers, or ſpices; as violets, jeſſamine, cinnamon, &c.

The *eſſences* to be drunk, or mixed, with liquors, are of a more elaborate compoſition: the moſt uſual, and beſt, is prepared with ſpirit of wine, cloves, cinnamon, mace, long-pepper, and coriander. The whole, being put up in a very cloſe veſſel, is expoſed to the ſun for ſix weeks, or two months, during the day-time, and in the night ſet near the fire.

In winter they uſe the fire alone. This *eſſence*, being exceedingly ſtrong, is frequently uſed only to give a ſtrength to other weaker liquors. After the ſame manner may the *eſſences* of ambergriſe, muſk, &c. be drawn.

The *eſſence* of odoriferous flowers, to give a fine ſmell to liquors, is drawn by diſpoſing ſtrata, or lays, of the flowers, and of ſugar, alternately, in a proper veſſel, and leaving them to infuſe, in a cellar, for twenty-four hours; and after that, as long in the ſun; and, laſtly, ſtraining, or percolating, the whole through a ſieve, without ſqueezing the flowers.

ESSENCE *of roſes*. See ROSES.

ESSENCE, *Ward's*. See WARD'S *Medicines*.

ESSENCE *of wine*, a term uſed by Paracelſus, and ſome of the German chemiſts ſince his time, to expreſs what is called ſometimes the philoſophical ſpirit of wine, or the ſpirit of wine of the ancients. It is not a diſtilled ſpirit like what we call ſpirit of wine, but approaches more to what Stahl has greatly recommended to the world, under the name of concentrated wine, or wine whoſe ſtrength has been reduced to a ſmaller compaſs, by ſeparating its aqueous part only by freezing. Stahl recommends the immediately expoſing of wine to the froſty air on this occaſion; but the proceſs ordered by Paracelſus for the preparation of this liquor is more tedious. He orders that the fineſt and beſt flavoured wine be choſen; that it be put into a glaſs, filling it up three parts in four: and the neck being then ſealed hermetically, it is to be put into horſe-dung for three months, and then expoſed to the froſty air for a month, after which the ice is to be thrown away, and the liquid part, which is the *eſſence*, preſerved. Shaw's Chemical Eſſays.

ESSENDO *quietum de tolloniis*, in *Law*, a writ to be quit of toll, and lies for citizens and burgeſſes of any city or town that by charter or preſcription ought to be exempted from toll, where the ſame is exacted of them. Reg. Orig. 258.

ESSENI, ESSENES, or ESSEANS, an ancient ſect among the Jews.

As to the etymology of the name, critics have been much divided. Philo derives it from ὅσιος, *holy*; Epiphanius from יהוה, *Jehovi*, *Jeſſe*, the father of David; Salmaſius from a city called *Eſſa*, mentioned by Joſephus; whence he apprehends the ſect firſt ſprung: Godwin derives it from the Syriac word חסן, *aſa*, which ſignifies *to heal*; becauſe Philo calls one branch of the *Eſſenes* therapeutæ;

and Serrarius enumerates at least a dozen different etymologies. Philo in Tract. Omnis probus Liber. Oper. p. 678. Colon. Allobr. 1613. Epiphan. Haref. xix. lib. 1. Salmaf. Plin. exercit. in Solin. cap. 35. Serrar. Trihæres. Jud. lib. iii. cap. 1. p. 106. 2to. edit. Tingland. 1703.

The principal ancient writers, who give any considerable account of the *Eſſenes*, are Joſephus, Philo, and Pliny. Joſ. de Bell. Jud. lib. ii. cap. 4. cap. 8. & 12. and Antiq. lib. xviii. cap. 2. 13. 19. lib. xviii. cap. 1. & cap 2. & alibi. Philo, ubi ſupra, & De Vita contemplativa, p. 688. ed. Col. Allobr.

As to the origin of this ſect, Pliny aſſerts, without mentioning his authority, that it had ſubſiſted for ſeveral thouſand years. The moſt probable opinion is, that this ſect was formed by Jewiſh exiles, a little before the time of the Maccabees, who were forced to fly from the perſecution of their enemies into caves and deſerts. The firſt *Eſſeni*, we read of are mentioned in the fourth book of Maccabees, under the name of Haſſidæi, and by Joſephus; both which accounts agree, that they were already ſettled in Judæa, in the time of Jonathan, the brother and ſucceſſor of Judas Maccabæus, about a hundred and ſixty years before Chriſt. Philo and Joſephus agree, that their number in Judæa was about four thouſand; but Philo makes the number in Egypt much greater. Some have expreſſed their ſurprize, that no mention ſhould be made of this ſect in the New Teſtament. This proceeded, as ſome imagine, from their retired mode of living, by reaſon of which they never came under our Saviour's obſervation, as the Phariſees and Sadducees often did. Others ſuppoſe, that, being very honeſt and ſincere, without guile or hypocriſy, they gave no reaſon for that reproof and cenſure, which the others very juſtly merited. Prid. Conn. vol. iii. p. 384. However, it has been ſuppoſed, that they are referred to by the apoſtle Paul in his Epiſtle to the Coloſſians, ch. ii 18, 21, 23.

Joſephus, making mention of the ſeveral ſects among his countrymen, diſtinguiſhes three; viz. the Phariſees, Sadducees, and *Eſſeni*; which laſt he prefers to the two former, as to their manner of life. He aſſures us, further, that they were Jews, by original; from which it ſhould appear, that St. Epiphanius was miſtaken in ranking them among the Samaritans.

In effect, the *Eſſeni* appear to have been true Pythagorean philoſophers, in every thing that related to their manner of living; for they greatly affected ſolitude and retirement, and avoided all converſation with women, to devote themſelves more entirely to the contemplative life. Grotius will have the *Eſſeni* the ſame with the ancient חסידים, *Haſidim*, or *Haſidæi*; thus called, according to Philo, from their ſingular piety, humility, and devotion. Among theſe, Gale obſerves, it was, that the Hebrew philoſophy chiefly flouriſhed. Porphyry is very prolix in his praiſes of the *Eſſeni*: Εασι γαρ ου Ἑβραιων ἐθνος μονον ἀλλα τον ἁπαντων, &c. He repreſents them as deſpiſers of pleaſures, riches, glory, and delicacy; and ſtrenuous retainers of continency, auſterity, ſtudy, &c. He adds, they decline marriage, and adopt and educate other people's children in the principles of religion and philoſophy; they are all on a level, hold every thing in common, neither buy nor ſell, &c. By long habit, they arrived at ſuch a degree of patience, that Porphyry aſſures us flames and tortures had not the leaſt effect on them. They ſcorned to intreat their tormentors; nor ever ſhed a tear; but would ſmile under all their agonies, &c. As to their learning, Philo Judæus, in his treatiſe, That every good Man is free, tells us, that they deſpiſed logic, as uſeleſs to the acquiring of virtue; phyſics they left to the ſophiſts and diſputants, as judging it to tranſcend the human faculties; and applied themſelves wholly to morality. Porph. de Abſtin. lib. iv. § 11. ſeq. Gale Philoſ. Gener. lib. i. cap. 1. § 11.

Both Joſephus and Philo give a ſurpriſing account of their auſtere way of life, which the curious reader may ſee at large in Prideaux's Conn. ubi ſupra. Their houſes were mean; their cloaths made of wool, without any dye; they never changed their cloaths or ſhoes, till they were quite worn out; their food was plain and courſe, and their drink water; they neglected all bodily ornaments, and would by no means anoint themſelves with oil, according to the faſhion of thoſe times. They lived in ſocialties, and had all their goods in common; their morals were very exact and pure, and they kept the Sabbath more ſtrictly than any of the Jews. Before any of them were admitted to the common table, they bound themſelves by a ſolemn oath to obſerve the rules of the ſociety which were very ſtrict and exemplary.

Some have ſaid that the *Eſſenes*, as well as the Pythagoreans, prohibited oaths; that they uſed only inanimate ſacrifices, and that they not only worſhipped towards the riſing ſun, but worſhipped the ſun itſelf. But it has been urged, that neither of theſe charges ſeem to be well founded; or at leaſt, that it is difficult to reconcile them with their known veneration for the writings of Moſes, and other inſtances of their conduct. Pliny, and others on his authority, have aſſerted, that they wholly deſpiſed marriage; and Pliny (lib. v. cap. 17.) with more wit than juſtice, ſays, that for ſeveral thouſands of years this people is perpetually propagated without any being born among them, ſo fruitful and proliſic were others in the repentance of others. But Joſephus informs us (De Bell. Jud. lib. ii. cap. 1.) that there was one ſect of the *Eſſenes*, who agreed with the others, except in the article of marriage. For they reckoned, that thoſe that do not marry cut off a great part from the number of the living, and that thus the whole race of mankind would ſoon be extinguiſhed. Accordingly they made choice of thoſe women, who, after three years trial, were found fit to bear children, and never cohabited with them after they were known to be with child; conſulting the propagation of their ſpecies, and not their own gratification in this buſineſs.

With reſpect to the religious opinions of the *Eſſenes*, they believed the exiſtence of angels, the immortality of the ſoul, and a future ſtate of rewards and puniſhments, but denied the reſurrection of the body. They maintained, that fate governs all things, and that nothing happens to man but by its appointment.

The *Eſſeni* ſeem to have been, among the Jews, what the moſt retired and auſtere monks are, or were, among the Chriſtians; which was what gave them their denomination of *Eſſenes monachi*, *Jewiſh ſcenites*.

Many catholic writers have even deduced the origin of monks from them; building, principally, on what Philo relates of them, who divides them into two branches, or ſects; the one who married, and the other who lived in celibacy.

Joſephus ſeems likewiſe to have had an eye to theſe two ſorts of *Eſſeni*. Serrarius, who has wrote very amply on the ſubject, follows Philo, in making two claſſes of *Eſſeni*. The firſt are thoſe whom he calls *Practici*, and who lived in community; the ſecond, thoſe called *Theoretici*, who lived in ſolitude, and led a life of pure contemplation. He adds, that Joſephus only makes mention of the firſt; omitting the contemplative kind, whom Philo calls *Therapeutæ*, and who were principally found in Egypt. See THERAPEUTÆ.

Euſebius holds, that the *Eſſeni*, called *Therapeutæ*, were real Chriſtians, or Jews converted by St. Mark, who had embraced this kind of life. Scaliger, on the contrary, maintains, that theſe *Therapeutæ* were no Chriſtians, but real *Eſſeni*, who made profeſſion of Judaiſm: however, he allows of the two kinds of *Eſſeni* above mentioned. But Valeſius, in his notes on Euſebius, abſolutely rejects any ſuch diſtinction: he denies, that the *Therapeutæ* were any real *Eſſeni*; and that chiefly on the authority of Philo himſelf, who never calls them *Eſſeni*, and who places the *Eſſeni* in Judæa and Paleſtine, whereas the *Therapeutæ* were ſpread throughout Greece, Egypt, and other countries.

Some traces of the *Eſſenes* are found under the emperor Trajan, and under Juſtinian; but they were much degenerated from their primitive purity both of doctrine and manners; and the ſect about that time became extinct. Though the *Therapeutæ*, as well as the *Eſſenes*, were ſtrictly Jews, and not Chriſtians, it is not impoſſible but that ſome of them, becoming Chriſtians, might ſtill affect their former recluſe way of living; and being encouraged by others, lay the foundation of monkery among Chriſtians.

ESSENTIA *dulcis*, in *Chemiſtry*, a name given by Kunkel, and ſome others of the German authors, to a menſtruum of which they relate wonderful effects; but the preparation of which ſeems hitherto a ſecret. They ſay this menſtruum has nothing acid or corroſive in it, but that it approaches to the nature of ſpirit of wine, yet that it is capable of diſſolving the moſt deadly metals, and of converting any of them into a pure white ſalt, which has all their virtues, but nothing of that vitriolic acrimony, which they have when prepared in the common way. The ſalts of mercury and of gold thus prepared, have great praiſes beſtowed on them, and are ſaid to cure epilepſies, the venereal diſeaſe, and many other diſtempers, without any violence or danger. Kunkel. De Salis Meral. See METAL.

ESSENTIAL, ſomething that is neceſſary to conſtitute a thing, or that has ſuch a connexion with the nature and reaſon of a thing, that it is found, or ſuppoſed, wherever the thing itſelf is.

Thus, it is *eſſential* to God to be juſt. Mr. Locke has laboured to overturn that great principle of the Carteſians, that thinking is *eſſential* to the ſoul.

The heart, brain, and ſpinal marrow, are parts ordinarily

rily supposed *essential* to life, or without which life cannot be; yet we have instances, in history, of children being found, and alive, without almost any of those parts. See BRAIN &c.

ESSENTIAL *oils* are such as are really contained in a plant, and are drawn from it, by distillation, in an alembic, with water: they are thus called, in contradistinction to empyreumatic oils, which are raised by a naked fire, without water. See OILS.

ESSENTIAL *properties*, are such as necessarily depend on, and are connected with, the nature and *essence* of any thing, so as to be inseparable from it; in distinction from *accidental*.

ESSENTIAL *salts*, are those prepared from decoctions, or those which are found crystallized in the juices or infusions of plants; in contradistinction to those made by incineration. See SALT.

ESSENTIAL *Fever, Form, Mode, Part, Perfection*. See the substantives.

ESSERE, SORA, and SARE, in *Medicine*, are little pathes or wheals, somewhat red and hard, which quickly infect the whole body with a violent itching, as if one were stung with bees, wasps, flies, or nettles; and therefore called the nettle-rash; yet they vanish after a little time, and leave the skin as smooth and well-coloured as before. It differs from an *epinyctis* in this, that an *epinyctis* sweats out matter, but an *essere* does not.

ESSES, in *Military Language*, are fixed to draught chains, made in the form of an S; one end of which is fastened to the chain, and the other to hook to the horse's harnesses, or to a staple; they serve likewise to lengthen and pierce chains together.

ESSOINERS, in *Law*, persons appointed by a court of law, to whom a writ of *venire facias* is directed, to impanel a jury, on challenge to the sheriff and coroners. They are to return the writ in their own names, with a panel of the jurors names. 15 Edw. IV. 24. pl. 4.

ESSOIGN, or ESSOIN, in *Law*, an excuse for him who, being summoned to appear and answer to an action real, or to perform suit to a court baron, &c. cannot attend, because of some legitimate hindrance.

The word is formed of the French *essoine*, or *exoine*; and that from the barbarous Latin *essonia*, or *exonia*, which signifies the same.

The causes that serve to *essoin*, are diverse; yet they may be reduced to five heads. The first is, *essoin de ultra mare, when the party is beyond sea*; the second, *de Terra Sancta, when on an expedition in the Holy Land*; the third, *de malo veniendi, when he is infirm of body, and cannot come*; which is also called the *common essoin*; the fourth, *essoin de malo lecti, when the defendant is sick a-bed*; the fifth, *de servitio regis, when he is in the king's service*. Horn mentions several other *essoins* touching the service of the king celestial, &c.

ESSOIGN *day of term*, is the first day of that term, when the court sits to take *essoins*, or excuses, for such as do not appear according to the summons of the writ. But the person summoned hath three days grace beyond the return of the writ, in which to make his appearance; and if he appears on the fourth day inclusive, the *quarto die post*, it is sufficient.

ESSOIGN *de malo villæ*, in *Law*, is when the defendant is in court the first day, but gone without pleading; and being afterwards surprised with sickness, &c. cannot attend, but sends two *essoiners*, who openly protest in court that he is detained by sickness in such a village, that he cannot come *pro lucrari & pro perdere*; and this will be admitted: for it lieth on the plaintiff to prove, whether the *essoign* is true or not.

ESSOINS, *clerk of the*. See CLERK.

ESSORANT, from the French *essorer*, *to air, in order to dry*, in *Heraldry*, a term us'ed to express a bird standing on the ground with the wings expanded, as if it had been wet, and were drying itself.

ESTABLISHMENT *of dower*, in *Law*, is the assurance and settlement of *dower*, made to the wife by the husband, on marriage; and *assignment of dower*, signifies the setting it out by the heir afterwards, according to the *establishment*.

ESTACHE is used in our *Old Writers*, for a bridge or stank of stone and timber.

ESTANDARD. See STANDARD.

ESTATE, in *Law*, the title, or interest, a man hath in lands, or tenements.

Estates are acquired diverse ways, viz. by descent from a father to the son, &c. conveyance, or grant, from one man to another; by gift or purchase, deed, or will; and a fee-simple is the largest *estate* that can be in law. 1 Inst. 541.

Estates are real, of lands, &c. or personal, of goods and chattels; otherwise distinguished into freeholds that descend to the heir, and chattels, which go to the executor.

Estate likewise is either simple or conditional. See FEE-*simple*, and FEE-*tail*.

The word *estate* generally, in deeds and grants, comprehends the whole, in which the party hath an interest or property; and will pass the same. 3 Mod. 46. See FEE, and TAIL.

ESTATE, *addition of*. See ADDITION.

ESTATE, *base*. See BASE.

ESTATE, *que*. See QUE *estate*.

ESTATE, or simply STATE, denotes also the empire, kingdom, province, or extent of lands, under the government of any sovereign.

The *estates* of the grand seignior, of the king of Spain, &c. are very extensive; those of the king of France are compact, and well peopled. Italy is cantoned out into a great number of petty *estates*. We say, ministers of *estate*, secretaries of *state*, &c.

ESTATE, or STATE, is also generally applied in the same sense with class or order; thus, the lay part of his majesty's subjects, or such of the people as are not comprehended under the denomination of CLERGY, may be divided into three distinct *estates* or *states*, the CIVIL, the MARITIME, and the MILITARY.

ESTATE is more particularly applied to the several ranks, or classes, of a people assembled together, for concerting measures, reforming public abuses, or composing the disturbances of a state.

In England, the three *estates*, viz. king, lords, and commons, meet ordinarily in parliament. In France, the *estates* consist of the churchmen, the nobility, and the people, or third *estate*. Some will have these assemblies of *estates* to be a very ancient constitution: all we know is, that there were general assemblies held, among the Gauls, before Cæsar's conquest; but then the people, or third *estate*, had no share in them. Under the first and second race of the French kings, there were also solemn convocations, called *parliaments*; but the great lords of the realm were the only persons that were called to them. See PARLIAMENT.

ESTATES *General*. } See STATES *General*, &c.
ESTATES *of Holland*. }

ESTERLING, or EASTERLING. See STERLING.

ESTETE, in *Heraldry*, is used by the French to signify a beast whose head has been, as it were, torn off by force; and, consequently, the neck left rough and ragged; in contradistinction to *decapité*, or *decapite*, where the neck is left smooth; as if the head had been cut off.

ESTHER, a canonical book of the Old Testament; denominated from a celebrated Jewish captive of that name, in Persia, whose beauty preferred her to the bed of Ahasuerus (supposed by some to have been Darius Hystaspes, by others Xerxes, but probably Artaxerxes Longimanus, though Jacob. Capellus makes him to be Ochus, called in Persia *Achasch-Verosch*), and the throne of Persia; and who, in that quality, saved her countrymen, the Jews, from the death to which Ahasuerus had doomed them, by the counsels of his favourite Haman; the history of which transaction makes the subject of the book of *Esther*.

The critics are divided about the author of this book: St. Epiphanius, St. Augustine, and Isidore, attribute it to Ezra; but Eusebius will have it to be of a later date. Some ascribe it to Joachim, high-priest of the Jews, and grandson of Josedek; others will have it composed by an assembly, or synagogue, of the Jews, to whom Mordecai wrote letters, informing them of what happened. Esth. ix. 29.

But the generality of interpreters, Hebrew, Greek, Latin, &c. ascribe the book to Mordecai himself; Elias Levita, in his Mass. Hamoun. præf. 3. mentions this opinion as unquestionable.

It is chiefly founded on that passage, chap. ix. ver. 20. where it is said, that *Mordecai wrote those things, and sent letters unto all the Jews, that were in all the provinces*, &c. It is also supposed, that queen *Esther* herself might have some share therein: it being expressed, in the same chapter, ver. 29. that *Esther* and Mordecai wrote a second letter, by the king's authority, to ordain the solemnizing a yearly feast, called *purim*, that is, *days of lots*, in commemoration of the Jews being delivered from the lots, or fortes, whereby they had been condemned.

Some will have this book to be only deuterocanonical, or apocryphal; others contend for its being canonical, as far as chap. x. ver. 3. inclusive; and all the rest deuterocanonical. Of this sentiment are, St. Jerome, De Lyra, Dionysius the Carthusian, Cajetan, and others. The council of Trent turned the scale for its being canonical throughout; so that the matter is determined for the Catholic countries.

But the protestants retain the old opinion, and only admit it as far as the third verse of the tenth chapter; the rest, to the end of the fifteenth chapter, is thrown among

among the apocryphal books. See DEUTERODANONICAL, and APOCRYPHAL.

ESTIÆA, *Festus*, in *Antiquity*, solemn sacrifices to Vesta, called in Greek τρία, of which it was unlawful to carry any away, or communicate any part to any beside the worshippers. Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 356.

ESTIATORES, *Εστιατορες*, among the Athenians, persons appointed by lot to provide an entertainment for the whole tribe. Besides those appointed by lot to this office, others voluntarily undertook it to ingratiate themselves. Potter, Archæol. Græc. lib. i. cap. 15. tom. i. p. 85.

ESTIMIONE, in *Natural History*, a name by which some call the *harmelion*.

ESTIVAL *accident*. See OCCIDENT.

ESTIVAL *orient*. See ORIENT.

Estival solstice. See ÆSTIVAL, and SOLSTICE.

ESTOILE. A *Croix* ESTOILE' is a Bar with only four long rays, in manner of a crois; and accordingly, broad in the centre, and terminating in sharp points.

ESTOPPEL, formed of the French *estoupar, appilare, obstipare, to stop, or block up*, in *Law*, an impediment, or bar, of action, arising from a man's own act, or deed; against which a man is forbidden, by law, to speak, though it be to say the truth. See BAR.

Goddard defines an *estoppel* to be, any bar, or hindrance, to one to plead the truth; and extends it not only to the impediment given by his own act, but by another's also. There are three kinds of *estoppel*; viz. by *matter of record*, by *matter in writing*, and by *matter in pais*.

ESTOVERS, in *Law*, is used, by Bracton, for that sustenance which a man, committed for felony, is to have out of his lands, or goods, for himself and his family, during imprisonment.

In that. 6 Edw. I. it is used for an allowance in meat, or cloaths. In some manors, the tenants have *common of estovers*; that is, necessary botes, or allowances, out of the lord's wood: in which laft fenfe, *eftovers* comprehends *house-bote, hay-bote*, and *plow bote*; fo that if a man have in his grant thefe general words, *de rationabili eftoverio in boscis*, &c. he may thereby claim all three.

Eftovers is alfo ufed for ALIMONY, which, if the husband refufes to pay, there is, befides the ordinary proceft of excommunication, a writ at common law, *de eftoveriis habendis*, in order to recover it.

ESTRAC, in the *Manege*, fignifies a horfe that is light bodied, lank-bellied, thin-flanked, and narrow-cheeked. See BELLY.

ESTRADE, a French term, literaly fignifying a *public road*, or *high-way*. Hence the military phrafe, *battre l'eftrade, to beat the eftrade*, that is, to fend fcouts, or horfemen, to get intelligence, to learn the difpofitions of the enemy, and inform the general of every thing likely to fall in the way. An army never marches, without fending *batteurs d'eftrade* on every fide.

The word is formed of the Italian *ftrada, ftreet, or road*; which is derived from the Latin *ftrata, a paved ftreet*. Some derive it from *eftradiots*, who were cavaliers anciently employed in *beating the eftrade*.

ESTRADE is alfo ufed for a little elevation on the floor of a room, frequently encompaffed with an ALCOVE, or rail, for placing a bed in; and fometimes, as in Turky, only covered with fine carpets, for receiving vifitors of diftinction.

ESTRANGEL, ESTRANGELUS, in the Syriac *Grammar*. *Eftrangel character*, is a particular fpecies, or form, of Syriac letters; ferving as the majufcule letters in that language.

Abraham Ecchellenfis takes the *eftrangel* character for the true ancient Chaldee character; and it is certain, the Abyffinians, who call themfelves Chaldeans, ftill occafionally ufe the *eftrangel* character, if we may credit Hottinger, in his Thefaur. Philol. p. 286. Bifhop Walton, in his Prolegomena, gives us an *eftrangel alphabet*.

ESTRAPADE, in the *Manege*, is the defence of a horfe that will not obey, but to get rid of his rider, rifes much before, and while his fore-hand is yet in the air, yerks furioufly with his hind-legs, ftriking higher than his head was before; and during this countertime goes back rather than advances.

ESTRAY, or STRAY, fignifies any tame beaft, as fheep, oxen, fwine, and horfes, or fwans, found within a lordfhip, and not owned by any man; in which cafe being cried, according to law, in the church, and two market-towns adjoining, if it be not claimed by the owner, within a year and a day, it becomes the lord's of the foil where found. If the owner claims it within the year and day, he muft pay the charges of finding, keeping, and proclaiming; and he may feize it, without telling the marks, or proving his property, which may be done at the trial, if contefted. If the beaft ftray within the year to another lordfhip, the firft lord cannot retake it. An *eftray* muft be fed and kept, unhurt, and without labour, till it is reclaimed, or the limited time expires.

ESTREAT, *Extractum*, in *Law*, is ufed for the true copy, or duplicate, of fome original writing, efpecially of amercements, or penalties, fet down in the rolls of a court, to be levied by the bailiff, or other officer, on every offender.

ESTREATS, *clerk of the*. See CLERK.

ESTREPEMENT, in *Law*, an impoverifhing, or making of land barren, by continual plowing and fowing, without due manuring, reft, and other husbandry.

The word is derived from the French *eftreper, to make*, or the Latin *exterpare, to extirpate, root up*.

ESTREPEMENT is alfo ufed for any waite, or fpoil, made, by the tenant for life, upon lands, or woods, to the prejudice of him in reverfion; as the cutting down of trees, or lopping them farther than the law allows, &c.

ESTREPEMENT is alfo a writ which lies in two cafes: the one, when a man having an action depending, as a freehold, writ of right, or the like, fues to inhibit the tenant from making waite during the fuit.

The other is for the demandant, who is adjudged to recover feifin of the land in queftion; and before execution, for fear of waite to be made till he can get poffeffion, fues out his writ.

ESULA, in *Botany*, a name given by many authors to fome of the fmall fpecies of SPURGE.

ESULA *rara*, in *Botany*, a name given by John Bauhine, and fevetal other authors, to a plant, called alfo by fome *alypum*, but properly a fpecies of dog's bane, and diftinguifhed by Mr. Tournefort by the name of *apocynum maximum Venetum folicis fubtus purpureis*, or the purple-flowered fea dog's bane of Venice, with willow-like leaves. See DOG's *Bane*.

ESULA *radix*, in the *Materia Medica*, the name of a root of a plant of the fpurge kind, fometimes ufed in medicine. The root conffting of a cortical part, and an inner flicky one, the bark only is ufed; and fuch fhould be chofen as is new dried, and of a reddifh colour without and withio, and fuch as when held in the mouth affords a very difagreeable tafte, with great acrimony. It is a very violent purge, and has been faid to have performed cures in defperate cafes, when more gentle medicines have proved ineffectual. It is a good method to macerate it a day or two in vinegar before it is ufed.

The plant which produces it, is the *efula rotunda et officinarum* of Mr. Ray: it is cultivated by fome curious people in their gardens.

ESURINE *falts*, in fome authors, denote thofe of a fretting, eating, or corroding nature; which chiefly abound in places near the fea-fide, and where a great quantity of fea-coal is burnt; as appears, from the fpeedy rufting of iron in fuch places.

ESUS, in *Mythology*, a deity among the Gauls, to which they facrificed after victory whatfoever came alive into their poffeffion. They fometimes fprinkled the altars of this deity with the blood of their women and children.

ETAPPE, in *War*, an allowance of provifions and forage, made to the foldiers, upon march through a kingdom, or province, or from winter quarters.

Hence, he that contracts with the country, or territory, for furnifhing the troops in their march is called *etappier*.

ETCH. See EDNISH.

ETCH *crop*, among *Farmers*, the third crop of corn upon land newly broke up. DICT. Ruft.

ETCHING, a method of engraving on copper; wherein the lines, or ftrokes, inftead of being cut with a tool, or graver, are eat with aqua fortis.

Etching was invented about forty or fifty years after ENGRAVING on copper, properly fo called, probably by Albert Durer and Lucas. It has feveral advantages peculiar to itfelf, and which renders it, on fome accounts, preferable to engraving: as, that it is done with greater eafe and expedition; that it requires fewer inftruments; and even that it repreſents divers kinds of fubjects better and more agreeable to nature, as landfcapes, ruins, grounds, and all fmall, faint, loofe, remote objects, buildings, &c. The inftruments employed in *etching* are needles, ftilts, oil-ftones, fcrapers, and brufh-pencils.

The needles are of the common kind, mounted on ſticks about fix inches long; and the artift fhould be provided with ſeveral of various fizes and fharpnefs. The ſtilt is a needle, the point of which is blunted and polifhed, that it may glide freely over the paper, without ſcratching or cutting it: this is ufed for calking and overtracing the deſign on the varnifh. The oil-ſtones are well known; with reſpect to which it may be remarked, that they ſhould be ſo ſoft, as not to take too faſt hold of the

needles, but to give a keen, smooth edge. See SCRAPER. The brush pencil ſhould be large and ſoft, of camel's hair, and is uſed for cleaning the ſurface of the varniſh after the engraving, and for other purpoſes.

The method of *etching* is thus: the plate, being well poliſhed (ſee COPPER-*plate*) is put upon a chafing diſh, and heated over the fire; or, if ſmall, is held with a hand-vice, the poliſhed ſide being upwards, and heated with the flame of paper burning under it; when hot, it is rubbed over with ſoft varniſh (ſuch as is deſcribed in the ſequel of this article) wrapped up in taffety, which ſhould be gently paſſed from one ſide to the other in a right line, ſo as to form ſeveral rows, till the plate is every where moderately covered; then with a cotton ball, tied up in taffety, let every part of the plate be heat gently, while the varniſh is in a fluid ſtate; and, in order to give it a fine grain, continue to beat it with the ball, after the plate is taken from the fire, till it attains a harder conſiſtence in cooling; but the uſe of the ball ſhould be diſcontinued before the varniſh is quite cold, leſt it ſhould be made to riſe from the plate.

When the plate is thus uniformly and thinly covered with the varniſh, it muſt be blackened by a piece of Bombeau, or of a large wax-candle, which affords a copious ſmoke; two, or even four ſuch candles are uſed together for the ſake of diſpatch, that the varniſh may not grow cold during the operation, which ſhould be performed, if poſſible, at one heating of the plate, for repeated melting of the varniſh does it much damage. Large plates may be ſuſpended from the ceiling of a room by four cords and iron rings, with the varniſhed ſide downwards, for the greater convenience of being blackened. Care ſhould be taken that the flambeau or candles be kept at a proper diſtance from the plate, that the wick may not touch the varniſh. The varniſh may be made white, if that colour is preferred to black, by grinding white lead in water, and putting it into a glazed earthen diſh, with a little good glue diſſolved, and melting the whole together. This mixture is ſpread with a brush or pencil of hog's hair thinly and evenly on the varniſh laid on the plate and ſmoothed. The colour is then left to dry; if it fixes with difficulty on the varniſh, the compoſition ſhould be mixed with a drop or two of ox-gall. On this ground, thus prepared, the back of the deſign or draught is laid. When this is done, the deſign remains to be called, or tranſferred upon the plate, which is more eaſily effected than in the common graving for the back of the deſign having been before rubbed over with red chalk, or ſtake-white, or, when the varniſh is whitened, with powdered black-lead, nothing remains but to trace over all the lines and ſtrokes of the draught with a needle or point; which, preſſing the paper cloſe down to the ground, occaſions the wax thereon to lay hold of the chalk, and ſo bring off the marks of the ſeveral lines, ſo as at length to ſhew a copy of the whole deſign in all its correctneſs. Inſtead of rubbing the back of the deſign with the red chalk or black lead, it may be proper in ſome caſes to ſpread the one or the other upon a piece of very thin paper of the exact ſize of the drawing, which ſhould be laid on the plate with the daubed ſide towards the varniſh under the drawing. The draught being thus calked, the artiſt proceeds to draw the ſeveral lines and contours with a point through the ground upon the copper. See CALQUING. When a picture or drawing is deſigned to be engraven on the ſame ſize, and turned the ſame way on the plate, ſo that the print will be turned to the oppoſite or contrary ſide to that of the original, a thin piece of paper, varniſhed with the Venetian varniſh, very dry and tranſparent, or thin fan-paper, oiled with linſeed oil, and perfectly dry, muſt be fixed to it: on this paper the lines of the original, which will appear through it, muſt be marked with a common *etching* point on the varniſhed paper, and with a black-lead pencil on the oiled paper, and afterwards calked upon the varniſh, by reddening the back of this paper with red chalk, or by interpoſing another very thin paper, not oiled, but reddened, between the oiled paper and the varniſhed plate. To finiſh his work, the artiſt makes uſe of points of various ſizes, and paſſes on them, ſometimes more ſtrongly, and ſometimes more lightly, as the ſeveral parts of the figures, &c. require a greater or leſs ſtrength or boldneſs; ſome of the points being as fine as needles for the tender fair ſtrokes, and the remoter fainter objects; and others again as big as bodkins, ſometimes made with oval points, for the deeper ſhadows and the figures in the front of the work. Theſe oval pointed needles have been rejected by ſeveral artiſts in working on the ſoft varniſh; they are uſeful only in engraving architecture: thoſe who are acculſtomed to the uſe of them may make the fineſt and ſmalleſt as well as the largeſt ſtrokes, and *etch* a whole plate without any other inſtrument, by ſurrowing it more or leſs, according to the magnitude of the intended ſtrokes. Some engravers uſe needles that do not cut at all, nor make any perceptible impreſſion on the copper. Care ſhould be taken to preſerve the ſoft varniſh on the plate, for which artiſts have various contrivances. The moſt eaſy way is to lay the plate on a table in form of a deſk, and to cover that part of the varniſh which allows of being covered in the engraving with a ſoft napkin of diaper or damaſk, folded evenly in four doubles, or with a piece of ſheep-ſkin dreſſed in oil, having the ſoft ſide turned towards the varniſh; or with a board called a bridge, ſuſpended at the ends by two pieces of wood about one fourth of an inch thick, juſt ſo as to let the plate lie freely under it. After all, if the varniſh ſhould be injured, the injury may be repaired by taking turpentine varniſh; and having tempered it with a little lamp-black, covering, by means of a ſmall pencil, the ſcratches, flaws, or falſe ſtrokes, with the mixture. The plates, thus repaired, may be equally well engraved upon with others, and therefore this modern invention is extremely uſeful. The ſame compoſition may alſo be applied to thoſe flaws occaſioned by the ſcaling of the varniſh, which ſometimes happens in the operation.

Things being thus prepared, a rim or border of wax, compoſed of four parts of common bees wax, and one part of Burgundy pitch melted together, is raiſed round the circumference of the plate covered with the varniſh, and aqua fortis poured on, which is kept by the ſaid border from running off at the edges. The ground being impenetrable to that corroſive water, the plate is defended from it every where but in the lines or hatches cut through it with the points, which lying open, the water paſſes through them to the copper and eats into it to the depth required; and when this is done, it is poured off. Of *etching* grounds there are two kinds, the one ſoft and the other hard: the latter was formerly much uſed, being better accommodated to the intention of imitating the engraving with the tool; but the former has now wholly ſuperſeded the uſe of the other, as it gives a power of expreſſion incompatible with the greater inflexibility of the hard varniſh that confines the lines and hatches to ſuch a ſameneſs and regularity as give a likeneſs of manner, and coldneſs of effect to the work. There are various directions for preparing the ſoft varniſh. Le Boſſe recommends the following: take of virgins wax, very white and clean, and of grains of maſtic, very clear and pure, each one ounce; and of calcined aſphaltum, half an ounce; grind the maſtic and aſphaltum ſeparately, very ſmall, and melt the wax over the fire in an earthen pot well glazed. When the wax is thoroughly melted, and very hot, ſprinkle the maſtic into it gradually that it may melt, and ſtir the mixture that the ingredients may incorporate. Then ſprinkle the aſphaltum into the mixture, ſtirring the whole compoſition over the fire till the aſphaltum be entirely melted: take the pot from the fire, and let the mixture cool; and pour the varniſh into clean water, and by working it with the hand, form it into a roll of about an inch in diameter, or into ſmall balls, which may be wrapt up in taffety and kept for uſe. The quantity of wax ſhould be increaſed in winter.

The following ſoft varniſh is uſed by many of the engravers at Paris: take of virgins wax, and aſphaltum of each one ounce; half an ounce of black pitch, and a quarter of an ounce of Burgundy pitch: the aſphaltum muſt be pounded in a mortar, and the wax melted over a ſlow fire in a pot of glazed earthen ware, and the reſt of the ingredients added by little and little, ſtirring the mixture till the whole be well melted and incorporated. Then throw the whole maſs into a veſſel of clean water, and proceed as before. The following preparation has been well approved: take of virgin's wax two ounces an a half; of Burgundy pitch, three ounces; of roſin, half an ounce; of aſphaltum, two ounces; and of turpentine, one pennyworth: the proceſs of making it is the ſame as the former.

Rembrandt prepared a white varniſh to be laid over a thin coat of any of the other kinds in the following manner; take of virgin's wax, one ounce; of maſtic, half an ounce; of calcined aſphaltum, or of amber, half an ounce: pound the maſtic and aſphaltum ſeparately in a mortar; and having melted the wax in a new earthen pot well glazed, ſprinkle them into it gradually, and ſtir the mixture, till the whole be incorporated. Pour the melted maſs into clean water, and form it into a ball for uſe. When this varniſh is uſed, the plate ſhould not be too much heated; the firſt coat of varniſh ſhould be laid very thin; and inſtead of blackening the varniſh with ſmoak, take a piece of ſtake white, and having ground it fine and tempered it with gum water, lay a thin coat of it with a pencil over the plate when it is quite cold. In this way Rembrandt varniſhed his plates.

There are alſo two kinds of aqua fortis; the one white, which is only uſed with the beſt ground, and applied as above directed: this is ſpirit of nitre, ſuch as is uſed by the refiners, except that it is not purified with ſilver. It may be prepared thus: take of the white kind of crude nitre, or of refined ſal-petre, twenty-four pounds; put it into a retort, and add twelve pounds of oil of vitriol: place the retort in a ſtrong ſand heat, and lute on to the retort a large receiver, containing about a gallon of water: diſtil over all that will riſe with a heat gradually increaſing: when the whole is cold, take off the receiver, and pour the aqua fortis into a bottle, and ſecure it with a glaſs ſtopper. This ſpirit of nitre is bought ready prepared of the chemiſts for four ſhillings a pound, and muſt be lowered with water; about one part of nitre to four or five parts of water is in general the proper mixture; but the nature of the work will indicate how much ſtronger or weaker it ſhould be. The green aqua fortis is not at all in uſe. It is to be obſerved that the aqua fortis muſt not continue equally long on all the parts of the deſign; the remote parts muſt be bitten more ſlightly than thoſe which are nearer to the view. To manage this they have a compoſition, which le Boſſe directs to be made thus: oil-olive is heated in a varniſhed earthen-ware pot, and the tallow of a candle is added to it; and the proportion of oil and tallow is aſſuſted by trying the mixture, and dropping it on any hard and cold ſubſtance till the drops are found to be moderately fixed and firm. It ſhould then be well boiled for an hour, till the mixture acquires a reddiſh colour. The following mixture is recommended by M. Cochin as a ſubſtitute for the oil and tallow, which is never uſed now: take equal parts of wax and turpentine, as much olive-oil as both of them together, with the ſame quantity of hogs lard: melt the whole in an earthen veſſel, mixing the ingredients, and leave them to boil for ſome time till they are well incorporated. With this compoſition, or with the turpentine varniſh and lamp-black mentioned before, they cover the parts that are to be bitten no farther. The conduct of the aqua fortis is one of the principal concerns in the whole art, and that on which the effect of the whole very much depends. The operator is alſo to be very attentive to the ground, that it do not fail or give way in any part to the water; and where it does, to ſtop up the place with the above compoſition. Laſtly, let it be remembered, that whenever the aqua fortis is taken off, fair water muſt be poured upon the plate; and it ſhould be dried with a very gentle heat, ſo as not to melt the varniſh. The aqua fortis may be applied as often as neceſſary, with this precaution. When the aqua fortis has done its part, the ground is taken off by warming the plate at the fire, and removing the border of wax; it is then more heated till the compoſition and varniſh melt, and wiped well with a clean linen cloth, and rubbed in every part with oil of olives. When the varniſh is taken off, pour upon it a ſmall quantity of olive-oil, rubbing the oil ſtrongly over every part of it, and clean the plate with a freſh linen cloth: after which, nothing remains but for the artiſt to examine the work with his graver in his hand, to touch it up, and heighten it where the aqua fortis, &c. has miſſed. The editor is indebted for the inſpection and correction of this article to the ingenious artiſt who executes the plates for this Dictionary. For the laws relating to *etching*, ſee ENGRAVERS.

ETERNAL *flower*, *xeranthemum*, in *Botany*, a genus of the *ſyngeneſia polygamia ſuperflua* claſs. Its characters are theſe: the flower is compoſed of hermaphrodite and female florets, which have one common ſcaly empalement. The hermaphrodite florets which form the diſk are funnel-ſhaped, and cut into five points: the female florets, which form the border or rays, are tubulous, and cut into five leſs equal points: the hermaphrodite florets have five ſhort ſtamina, terminated by cylindrical ſummits, and a ſhort germen ſupporting a ſlender ſtyle, crowned by a biſid ſtigma; the germen becomes an oblong ſeed crowned with hairs, which ripens in the empalement. There are ſix ſpecies.

We have ſeveral ſpecies of this plant cultivated in our gardens, and known in Engliſh by the name of *everlaſting flowers*, a name common to all the ſpecies of this plant, and of the amaranthoides.

Theſe flowers are of ſo dry and durable a ſtructure, that if gathered juſt when they are ripe, they will laſt many years in perfection, and appear as freſh as when growing: they are alſo capable of ſeveral tinges, and hence are often ſeen of fine blues and greens, colours not natural to them.

They are all propagated by ſowing their ſeeds in Auguſt, in a warm border, obſerving to water and ſhade them till they come up, if the weather proves too dry. When the young plants are two inches high they ſhould be removed to another warm border under the ſhelter of a wall, and there planted at five inches diſtance from each other. They will here ſtand the winter very well, and in ſpring will be ready to grow up for flowering without any farther tranſplanting: they are only to be kept clear of weeds, and in June they will flower. The flowers ſhould be gathered in July for drying, and ſome of the fineſt ſhould be ſuffered to ſtand for ſeed; for the plants periſh as ſoon as they have perfected their ſeeds, and muſt be renewed by ſowing every year.

ETERNITY, duration which is conceived incommenſurable with time, and excluſive of beginning, progreſs, ending, &c. See GOD.

Authors are much at a loſs for a proper and juſt definition of *eternity*: that of Boethius, De Conſol. Philoſ. lib. v. part 6. viz. *Interminabilis vitæ tota ſimul & perfecta poſſeſſio*, i. e. *a perfect poſſeſſion of a whole endleſs exiſtence altogether*, though retained by S. Thomas and others, is faulty in divers reſpects.

Cenſorinus, De Die Natal. defines *eternity* by infinite duration, that is, duration which has always been, and always will be. Others more fully deſcribe it by a duration that exiſts altogether without any flux or ſucceſſion of parts prior or poſterior to each other: where the word *duration*, taken abſtractedly, imports no more than the perſeverance of a thing in its exiſtence, the *to durare* being here oppoſed to the *to eſſare*, *in eſſendo*.

But ſoften the word duration how you will, it is ſcarce conceivable but by conceiving a quantity thereof, nor a quantity without conceiving a ſucceſſion. Others, therefore, define *eternity* by a *perpetuum nunc*, a *perpetual now*, or a *nunc ſtans ſtans*, an *ever-ſtanding now*; but neither are theſe unexceptionable, the words *perpetuum* and *ſtans ſtans* importing an obſcure ſort of duration. See DURATION.

ETERNITY, in *Mythology*, a divinity among the Romans, who had neither temples nor altars. They repreſented it under the figure of a woman, who held the ſun in one hand and the moon in the other: her ſymbols were a phœnix, globe, and elephant.

ETESIÆ, or ETESIAN *winds*, are ſuch as blow at ſtated times of the year, from what part ſoever of the compaſs they come. They are ſo called from the Greek word ἔτος, *year*, being yearly or anniverſary winds: ſuch as our ſeamen call monſoons and trade-winds, which, in ſome parts of the world, continue conſtantly blowing for certain ſtated ſeaſons of the year. Thus the north winds, which, during the dog-days, conſtantly blow upon the coaſts of Egypt, and hinder all ſhips from ſailing out of Alexandria for that ſeaſon, are called *eteſiæ* in Cæſar's Commentaries. In other authors, the weſt and eaſt-winds are called *eteſiæ*, when they continue blowing for certain ſeaſons of the year. Vide Salmaſ. Exercit. in Solin. p. 421.

Cellarius endeavours to prove that thoſe winds are properly *eteſiæ* which blow from that part of the horizon which is between the north and weſt about the time of the ſolſtice. Geog. Antiq. lib. i. cap. 8. See MONSOON and WIND.

ETHELING, or *Ætheling*. See ATHELING.

ETHER. See ÆTHER.

ETHERIAL *oil*. See ÆTHERIAL *oil*.

ETHESIUS *lapis*, a name given by ſome authors to the chryſolite.

ETHICAL *good*, ETHICAL *poſſible*. See the reſpective articles.

ETHICS, ἠθικὸν, the doctrine of manners, or the ſcience of moral philoſophy. See PHILOSOPHY and MORALITY.

The word is formed of ἦθος, *mores*, *manners*, becauſe the ſcope or object thereof is to form the manners.

Gale makes *ethics* only the firſt part or branch of moral philoſophy, viz. that which regards private perſons, or in a private capacity.

By manners or morals is here meant, a way or manner of living confirmed by cuſtom or habit, or certain habitudes of doing, or actions which are often repeated, which, if they be according to right reaſon, the morals or manners are ſaid to be good, otherwiſe, evil and vicious.

Hence the object of *ethics* is the exerciſe of right reaſon in all our affairs, actions, and relations; or it is man himſelf conſidered as diriginble, and to be conducted according to reaſon; and the end of *ethics* is to make him good and happy: ſo that if a man conducted himſelf according to right reaſon in all the circumſtances of his actions, affairs, and relations, he would arrive at the higheſt pitch of moral perfection and beatitude.

Whence *ethics* may be defined a right manner of thinking in order to attain to human felicity, or a ſcience whereby man is directed to conduct his will, and the

actions

actions thereof, so as to live well and happily. See WILL.

The principal, nay, the only topics thereof, are happiness and manners, whence arise two parts or branches of *ethics*; the first on moral happiness, considered as the end; and the second on moral virtues or good manners, as the means to arrive at that end.

ETHICOPROSCOPTÆ, formed of ἔθος, *manners*, and σκοπτωμαι, *I scoff*, in *Antiquity*, the name of a sect. Damascenus, in his Treatise of Heresies, tells us, that the denomination of *Ethicoproscoptæ* was given to such as erred in matters of morality and things relating to practice that were to be done or to be avoided, &c. who blamed things laudable and good in themselves, or recommended or practised things evil. On this footing the *Ethicoproscoptæ*, though a numerous body, were no particular sect.

ETHIOPIC *version*. See BIBLE, *Ethiopic*.

ETHIOPIC *year*. See YEAR.

ETHMOIDAL, ETHMOIDALIS, in *Anatomy*, a denomination given to one of the sutures of the human cranium.

The common sutures are those which separate the bone of the cranium from those of the cheeks, and are four; the transversal, *ethmoidal*, sphenoidal, and zygomatical. See SUTURE.

The *ethmoidal* takes its denomination from its turning round the os ethmoides.

ETHMOIDES, Ἠθμοειδὲς, in *Anatomy*, a bone situate in the middle of the basis of the forehead or os frontis, and at the top of the root of the nose, filling almost the whole cavity of the nostrils.

It has its name from ἠθμὸς, *cribrum*, *sieve*, and εἶδος, *form*, because all spongy and porous.

By its cribrous part, it is joined to the head; by the spongious part, to the cavity of the nostrils; and by the plain and broad part, to the orbits of the eyes.

In the cribrous part is an apophysis, which jets out in a point into the cavity of the skull, called from its figure *crista galli*, or the *cock's comb*. From its under side there goes a thin bone, which divides the cavity of the nostrils into two, called the *vomer*. It is perforated by a number of small holes, through which the fibres of the olfactory nerves pass.

J. Philip Ingrassias, a Sicilian, who was born in Sicily in 1510, and died in 1580, was the first who gave a just account of the structure of the *os ethmoides*, or *cribosum*, in a work printed at Palermo in 1603. *fol.*

The figure of this bone is very singular, and may be said to be in some measure cubical. This bone may be divided into a middle and two lateral portions; in the middle three parts may be distinguished, an upper, a middle, and a lower. The upper part of the middle portion is an eminence, called *crista galli*, which is often solid, sometimes, however, it has been found hollow in several degrees, and perforated by a small opening which communicates with the frontal sinuses: a groove is sometimes also met with in its anterior edge, which leads to the spinal or blind hole in the os frontis. The middle part of this portion is a small horizontal plate perforated by several holes, and called *lamina cribrosa*; and in its back part it has a little notch for its articulation with the sphenoidal bone; this lamina may be called the body of the bone, as being what principally supports all the other parts of it.

The lower part is a perpendicular lamina, which makes part of the septum nasium: the edge of this is rough and uneven, for its better connection with the vomer.

The lateral portions of the *ethmoidal* bone are by far the most considerable, if we regard size only; each of these may be divided into two, one superior, which is the largest, and which may be called the labyrinth of the nostrils, it being full of turnings and windings, and irregularly cellular; and one inferior, in the shape of a shell. It is of a very tender and delicate structure, though compact, and without any diploe, being almost all composed of thin bony plates. It is joined to the os frontis, os sphenoides, ossa nasi, ossa maxillaria, ossa unguis, ossa palati, and vomer; the use of it are to be a very principal part of the organ of smell; and to give a very great extent to the pituitary membrane in a small compass. Winslow's Anatomy, p. 29.

ETHNARCHA, ETHNARCH, formed of ἔθνος, *nation*, and ἄρχω, *command*, a governor and ruler of a nation.

There are some medals of Herod I. surnamed the *Great*, on one side whereof is found Ηρωδου, and on the other Εθναρχου, q. d. *Herod the Ethnarch*. After the battle of Philippi, we read that Antony passing over into Syria, constituted Herod and Phasael his brother tetrarchs, and in that quality committed to them the administration of the affairs of Judea. *Jos. Ant.* lib. xiv. cap. 23. Herod therefore had the government of the province before ever the Parthians entered Syria, or before Antigonus's invasion, which did not happen till six or seven years after Herod was commander in Galilee. *Jos. ibi.* xiv. cap. 24, 25. Consequently, Herod was then truly *ethnarch*, for he can be no otherwise denominated, so that it must have been in that space of time that the medals were struck, which only give him this title: which medals are a confirmation of what we read in history of the government which that prince was intrusted with before he was raised to the royalty.

Josephus gives Herod the appellation of *tetrarch* in lieu of that of *ethnarch*; but the two terms come so near to each other, that it is easy to confound them together. Though Herod the Great left by will to Archelaus all Judea, Samaria, and Idumea, yet Josephus tells us he was then only called *ethnarch*.

ETHNOPHRONES, in *Antiquity*, a sect of heretics in the seventh century who made a profession of Christianity, but joined thereto all the ceremonies and follies of paganism, as judicial astrology, soothsayers, auguries, and other divinations.

They derive their denomination from ἔθνος, *nation*, and φρὴν, *thought, sentiment*, q. d. *paganizers*, or persons whose thoughts or sentiments were still heathen or gentile.

They practised all the expiations of the gentiles, celebrated all their feasts, and observed all their days, months, times, and seasons. See Damascenus, Hæref. N° 94.

ETHOLOGUS, among the ancients, a mimic, or actor, who could represent all the various habits and dispositions of the mind.

ETHOPŒIA, or ETHOPŒA, in *Rhetoric*, called also ETHOLOGY, a draught or description, expressing the manners, passions, genius, tempers, aims, &c. of another person.

The word is of Greek original, being formed of ἔθος, *mos, manners*, and ποιεῖν, *facio, fingo, describo*. Quintilian, lib. ix. cap. 2. calls this figure *imitatio morum alienorum*; and in Greek, μιμησις, *imitation*. In English we denominate it a *picture*, or *character*.

Such is that beautiful passage in Sallust, in his Bellum Catilinarium, wherein he gives us a picture of Catiline: "he had an uncommon strength both of body and "mind, but an ill-turned and wicked disposition. "When very young, his great pleasure was in intestine "broils, rapine, slaughter, and civil discord. His body "was formed to undergo fasting, cold, and watching, "beyond all belief. His mind was daring, deceitful, "and various, and could imitate or accommodate itself "to every body: he was extremely covetous of other "people's goods, and profuse of his own. His lusts "and desires were very high; his stock of eloquence "considerable, but he had little or no discretion."

The *ethopœia* is divided into *prosopopœia* and *ethopœia*, properly so called: the former of which is a picture of the body, countenance, make, dress, gait, &c. and the latter of the mind.

ETHULIA, in *Botany*, a genus of the *syngenesia polygamia æqualis* class. The receptacle is naked, and the seed has no down. There are five species.

ETIQUETTE, a French term, primarily denoting a ticket or title affixed to a bag or bundle of papers, expressing its contents. It is also used when applied to the Spanish and some other courts, to signify a particular account of what is to be done daily in the king's household, and in the chief ceremonies relating to it. It likewise denotes those forms that regulate the decorum of conduct towards persons of various ranks and stations.

ETRUSCA *terra*, in the *Materia Medica*, a kind of bole of which there are two species, the white and the red; these are called by many authors the *terra sigillata alba & rubra magni ducis*, as they are brought to us sealed with different impressions.

The *white Tuscan earth* is a dense and compact substance of a dull deadish white, which in drying acquires some degree of yellowness; it is of a smooth surface, and does not stain the fingers in handling. It is not easily broken, and but slightly adheres to the tongue, and freely melts into a substance like butter in the mouth. It makes a slight effervescence with acid menstruums.

The *red Tuscan earth* is a pure bole, very heavy, and of a compact texture, and of a dull brownish red colour. It is naturally of a smooth surface, breaks easily between the fingers, and does not stain the hands; it adheres strongly to the tongue, and melts freely in the mouth, and has a strong astringent taste, and leaves no sandy harshness between the teeth. It makes an effervescence with acid menstrua. This is made up of small flat cakes, and impressed with a shield bearing a ducal coronet, &c. These are the characters by which both these earths may be known from others of the same colour: they are both dug in several parts of Italy, particularly

theory of *evaporation*, on of the afcent of water in fuch a fluid as air, between eight and nine hundred times lighter than itſelf, to different heights according to the different denſities of the air; in which caſe it muſt be ſpecifically lighter than the air through which it aſcends. The Carteſians account for it by ſuppoſing, that by the action of the ſun upon the water, ſmall particles of the water are formed into hollow ſpheres and filled with the *materia ſubtilis*, which renders them ſpecifically lighter than the ambient air, ſo that they are buoyed up by it.

Dr. Nieuwentyt, in his Religious Philoſopher, conſ. 17. and ſeveral others have alleged, that the ſun emits particles of fire which adhere to thoſe of water, and form *molecular*, or ſmall bodies, lighter than an equal bulk of air, which conſequently aſcend till they come to an height, where the air is of the ſame ſpecific gravity with themſelves; and that theſe particles, being ſeparated from the fire with which they were incorporated, coaleſce and deſcend in dew or rain. Dr. Halley has advanced another hypotheſis, which has been more generally received: he imagined, that by the action of the ſun on the ſurface of the water, the aqueous particles are formed into hollow ſpherules filled with a finer air highly rarefied, ſo as to become ſpecifically lighter than the external air. Phil. Tranſ. N° 192. or Abr. vol. ii. p. 126. Dr. Deſaguliers, diſſatisfied with theſe two hypotheſes, propoſes another in the Phil. Tranſ. N° 407. or Abr. vol. vii. p. 61. See alſo his Courſe of Experimental Philoſophy, vol. ii. p. 336, &c. He ſuppoſes that heat acts more powerfully on water than on common air; that the ſame degree of heat which rarefies air two-thirds will rarefy water near 14,000 times; and that a very ſmall degree of heat will raiſe a ſteam or vapour from water, even in winter, whilſt it condenſes the air; and thus the particles of water are converted into vapour by being made to repel each other ſtrongly, and deriving electricity from the particles of air to which they are contiguous, are repelled by them and by each other, and form a fluid, which, being lighter than the air, riſes in the air, according to their relative gravities. The particles of this vapour retain their repellent force for a conſiderable time, till, by ſome diminution of the denſity of the air in which they float, they are precipitated downwards and brought within the ſphere of each other's attraction of coheſion, ſo that they join again into drops of water. Many objections have been urged againſt this opinion by Mr. Clare, in his Treatiſe of the Motion of Fluids, p. 294, &c. and by Mr. Rowning in his Syſtem of Philoſophy, part. ii. diſſ. 6. to which Dr. Hamilton has added the two following, viz. that if heat were the only cauſe of *evaporation*, water in a warm cloſe room would evaporate faſter than when expoſed in a colder place, where there is a conſtant current of air, which is contrary to experience; and that the *evaporation* of water is ſo far from depending on its being rarefied by heat, that it is carried on even whilſt water is condenſed by the coldneſs of the air, for water is gradually condenſed till it falls in ſnow, and ſince it evaporates even when frozen into hard ice, it muſt alſo evaporate in all the leſſer degrees of cold. Heat, therefore, does not ſeem to be the principal, much leſs the only cauſe of *evaporation*.

Others have attempted to account for the phenomena of *evaporation* on another principle, viz. that of ſolution; and ſhewn, from a variety of experiments, that what we call *evaporation* is nothing more than a gradual ſolution of water in air, produced and ſupported by the ſame means, or by attraction, heat, and motion, by which other ſolutions are effected.

The Abbé Nollet ſeems to have been the firſt who ſtarted this opinion, without much purſuing it, in his Leçons de Phyſique Experimentale, the firſt edition of which was publiſhed in 1743: he offers it as his conjecture, that the air of the atmoſphere ſerves as a ſolvent or ſponge with regard to the bodies that encompaſs it, and receives into its pores the vapours and exhalations that are detached from the maſſes to which they belong in a fluid ſtate; and he accounts for their aſcent on the ſame principles with the aſcent of liquors in capillary tubes: on his hypotheſis, the condenſation of the air contributes, like the ſqueezing of a ſponge, to their deſcent. See the work above cited, fifth edit. 1767, tom. ii. p. 109, and p. 430. See VAPOUR.

Dr. Franklin, in a Paper of Philoſophical and Meteorological Obſervations, Conjectures, and Suppoſitions, delivered to the Royal Society about the year 1747, and read in 1756, ſuggeſted a ſimilar hypotheſis: he obſerves, that air and water mutually attract each other; and hence concludes that water will diſſolve in air, as ſalt in water; every particle of air aſſuming one or more particles of water; and when too much is added it precipitates in rain. But as there is not the *ſame* contiguity between the particles of air as of water, the ſolution of water in air is not carried on without a motion of the air, ſo as to cauſe a freſh acceſſion of dry particles. A ſmall degree of heat ſo weakens the coheſion of the particles of water, that thoſe on the ſurface eaſily quit it, and adhere to the particles of air: a greater degree of heat is neceſſary to break the coheſion between water and air. Air moderately heated will ſupport a greater quantity of water inviſibly than cold air; for its particles being by heat repelled to a greater diſtance from each other, thereby more eaſily keep the particles of water that are annexed to them from running into coheſions that would obſtruct, refract, or reflect the light; and hence it happens, that when we breathe in warm air, though the ſame quantity of moiſture may be taken up from the lungs as when we breathe in cold air, yet that moiſture is not ſo viſible. On theſe principles he accounts for the production and different appearances of fogs, miſts, and clouds. He adds, that if the particles of water being electrical fire when they attach themſelves to air, the repulſion between the particles of water electrified, joins with the natural repulſion of the air, to force its particles to a greater diſtance, ſo that the air being more dilated, riſes and carries up with it the water; which mutual repulſion of the particles of air is increaſed by a mixture of common fire in the particles of water. When air, loaded with ſurrounding particles of water, is compreſſed by adverſe winds, or by being driven againſt mountains, &c. or condenſed, by taking away the fire that aſſiſted it in expanding, the particles will approach one another, and the air with its water will deſcend as a dew; or if the water ſurrounding one particle of air comes in contact with the water ſurrounding another, they coaleſce and form a drop, and we have rain; and ſince it is a well-known fact, that vapour is a good conductor of electricity as well as of common fire, it is reaſonable to conclude with Mr. Henly, that *evaporation* is one great cauſe of the clouds becoming at times ſurcharged with this fluid. Phil. Tranſ. vol. lxvii. part i. p. 134. See Phil. Tranſ. vol. lv. art. 24. p. 182. or Franklin's Letters and Papers on Philoſophical Subjects, p. 42, &c. and p. 182, &c. ed. 1769. M. le Roi, of the Academy of Sciences at Paris, hath alſo advanced the ſame opinion, and ſupported it by a variety of facts and obſervations in the Memoirs, &c. for the year 1751. He ſhews, that water does undergo in the air a real diſſolution, forming with it a tranſparent mixture, and poſſeſſing the ſame properties with the ſolutions of moſt ſalts in water; and that the two principal cauſes which promote the ſolution of water in the air are heat and wind; that the hotter the air is within a certain limit, the more water it will diſſolve; and that at a certain degree of heat the air will be ſaturated with water; and by determining at different times the degree of the air's ſaturation, he eſtimates the influence of theſe cauſes on which the quantity ſuſpended in the air in a ſtate of diſſolution depends. Accordingly, the air, heated by evaporating ſubſtances to which it is contiguous, becomes more rare and light, riſes, and gives way to a denſer air; and, new being thus removed, contributes to accelerate the *evaporation*. The non-elaſtic air contained in the internal parts of evaporating bodies, put into action by heat, ſerves alſo to increaſe their *evaporation*, as is evident in the caſe of the ÆOLIPILE. The wind is another cauſe of the increaſe of *evaporation*, principally by changing and renewing the air which immediately encompaſſes the evaporating ſubſtances; and from the conſideration of theſe two cauſes combined, it appears why the quantity of vapour raiſed in the night is leſs than that of the day, ſince the air is then both leſs heated and leſs agitated. M. le Roi further ſhews, that winds blowing in particular directions are more favourable to *evaporation* than others; thus the north and north-weſt winds accelerate *evaporation* in Languedoc, and probably in other parts of Europe, and the ſouth-eaſt wind retards it. To the objection urged againſt this hypotheſis, on account of the *evaporation* of water in a vacuum, this ingenious writer replies, that the water itſelf contains a great quantity of air, which gradually diſengages itſelf and cauſes the *evaporation*; and that it is impoſſible that a ſpace containing water which evaporates ſhould remain perfectly free from air. To this objection a late writer, Dr. Dobſon of Liverpool, replies, that though air appears by unqueſtionable experiments to be a chemical ſolvent of water, and as *ſuch*, is to be conſidered as one cauſe of its *evaporation*, heat is another cauſe, acting without the intervention of air, and producing a copious *evaporation* in an exhauſted receiver; agreeably to an experiment of Dr. Irving, who ſays, that water in an exhauſted receiver riſes in vapour more copiouſly at 180° of Fahrenheit's thermometer than in the open air at 212° its boiling

point. Dr. Dobſon farther adds, that water may exiſt in air in three different ſtates; in a ſtate of perfect ſolution, when the air will be clear, dry, and heavy, and its powers of ſolution ſtill active; in a ſtate of beginning precipitation, when it becomes moiſt and foggy, its powers of ſolution are *diminiſhed*, and it becomes lighter in proportion as its water is depoſited; and alſo when it is completely precipitated, which may happen either by a more ſlow proceſs, when the diſſolved water falls in a drizling rain, or by a more ſudden proceſs, when it deſcends in brisk rain. Phil. Tranſ. vol lxvii. part i. p. 243. and Phipps's Voyage to the North Pole, p. 211. Dr. Hamilton, profeſſor of philoſophy in the univerſity of Dublin, tranſmitted to the Royal Society in 1765, a long Diſſertation on the Nature of *Evaporation*, in which he *poſpoſes* and eſtabliſhes this theory of ſolution; and though other writers had been prior in their conjectures, and even in their reaſoning on this ſubject, Dr. Hamilton aſſures us, that he has not repreſented any thing as new which he was conſcious had ever been propoſed by any one before him, even as a conjecture. Some of the facts alleged by profeſſor Hamilton, and ſome of the concluſions deduced from them, are ſimilar to thoſe of M. le Roi; but the ſimilarity appears to be merely accidental. The editor, having laid before the public a fair and impartial account of the hiſtory of the new theory, as it may be called, of *evaporation*, which is the moſt plauſible, and now the moſt generally received, will terminate this article with a brief view of Dr. Hamilton's arguments in ſupport of it, and the application of it to the phenomena of the atmoſphere. By ſolution, Dr. Hamilton underſtands with other writers, ſuch an intimate union between the particles of a body and thoſe of a fluid, that the whole ſhall appear an homogeneous maſs, as tranſparent as the fluid was before ſuch union, and ſhall continue ſo, till ſome external cauſe produces a change: he conſiders the tranſparence of the fluid as the criterion of a true ſolution, and that which diſtinguiſhes it from a mixture. He proceeds to ſhew, that there is a mutual attraction between the water and air of the ſame kind with that which is obſerved between the particles of any two bodies, one of which diſſolves the other. All water contains a conſiderable quantity of air which may be ſeparated from it; and as it retains its elaſticity, we may reaſonably ſuppoſe, that it is prevented from eſcaping by the force of attraction, juſt as the particles of gold are ſuſpended in *aqua regia*, by their attraction towards the particles of that fluid. Beſides, water exhauſted of its air will again imbibe a certain quantity, gradually drawing it into its pores till it is ſaturated, juſt as a lump of ſugar draws water into its pores. Air, likewiſe, evidently contains a quantity of water, which will be drawn from it even in its pureſt and drieſt ſtate by dry ſalt of tartar, ſo that the ſalt will become entirely fluid; and yet in this caſe the air is perfectly tranſparent. There is alſo a remarkable ſimilarity between the properties of common ſolutions and thoſe of *evaporation*. As ſalt beginning to diſſolve in water appears at firſt to thicken the water that ſurrounds it, and the ſolution of it to be promoted by agitation, the air that lies at reſt over water appears thick, and loaded with aqueous particles, in which caſe the *evaporation* proceeds very ſlowly, which is greatly promoted by a current of freſh air paſſing over the exhaling ſurface.

When a lump of any ſalt is diſſolved in clear cold water, the water that is firſt ſaturated with it will riſe on agitation in curled wreaths through the other water, render it ſomewhat opake, and give an apparent tremulous motion to an object ſeen through it, till by degrees the ſolution is complete, and the tranſparency of the water is reſtored: the caſe is the ſame when any two fluids of different denſities that will incorporate, are mixed together; thus, ſmoke or ſteam, when it firſt riſes into the air, exhibits ſimilar appearances; and the vapour riſing in a hot day from moiſt ground will make the air and any object ſeen through it appear to have a tremulous motion, which is ſtill more obſervable when a teleſcope is uſed, that magnifies the floating vapours. Farther, heat, by expanding bodies, enlarging the pores, and leſſening the mutual coheſion of their particles, promotes, and cold, on the contrary, in ſome meaſure retards and checks both ſolution and *evaporation*. As very hot water diſſolves ſalt ſooner, and in a greater quantity than cold water, and when cooled, depoſits part of the ſalt after a ſtrong ſolution, which was before diſſolved; ſo water will evaporate faſter in warm than in cold air; and therefore, the air is generally clearer in cold than in hot weather. Thus the aqueous vapours ſuſpended in the air during the heat of the day, fall down at night, and form themſelves in to drops of DEW, or if the night be very cold, appear next morning cryſtallized in a HOAR-FROST. If a bottle of very cold liquor be expoſed to the warm air in a hot day, the air contiguous to it being cooled, will let go part of its water, which will form a dew on the outer ſurface of the glaſs: by an experiment ſimilar to this M. le Roi was firſt led to conclude that water is really diſſolved in air: for the ſame reaſon a dew is formed on the inſide of the windows of a warm room, which on their outſide are expoſed to the cold air. Again, the quantity of a body diſſolved, and of a fluid evaporated, depends, *ceteris paribus*, on its quantity of ſurface. Chemiſts produce cold by ſolution: thus, by diſſolving pounded ice or ſnow in ſpirit of nitre, a degree of cold has been produced ſufficient to freeze quickſilver. See FREEZING and THERMOMETER. Cold is alſo produced by *evaporation*: ÆTHER, or ſpirit of wine, of the ſame temperature with the air, rubbed lightly (with a feather) over the bull of a thermometer, will make the quickſilver ſink as they evaporate; and the quicker they evaporate, the faſter will the quickſilver ſink: any volatile ſpirit rubbed over the hand feels much colder than water of the ſame temperature; and either feels colder than ſpirit, on account of their more ſudden *evaporation*.

M. Amiontons, in a Memoir of the Academy of Paris, 1699, and M. Richman, in a memoir of the Academy of Peterſburgh, 1747, have obſerved, that cold is produced by evaporating fluids; this phenomenon has been noticed alſo by M. Muiran in 1749, and by Muſchenbroek in his Eſſai de Phyſique; and Dr. Cullen has found, that the cold thus produced is nearly in the proportion of the volatility of the fluids, and that it is conſiderably greater in vacuo than in air. Eſſ. Phyſ. and Art. Edinb. vol. ii. 1756. See THERMOMETER. Profeſſor Braun has made a farther inveſtigation of this matter, by publiſhing a table of the deg ees of cold produced during the evaporation of different fluids. Nov. Comm. Petrop. tom. x. 1764.

Dr Franklin mentions a practice recorded in Bernier's Travels through Indoſtan, written near a hundred years ago, to this purpoſe: in travelling over dry deſarts in that hot climate, they carry water in flaſks wrapped in wet woollen cloths, and hung on the ſhady ſide of the camel or carriage in the free air, whereby as the cloths gradually grow drier, the water contained in the flaſks is made cool. Franklin's Letters, &c. p. 304.

Again, there is a ſtronger attraction or affinity between ſpirit of wine and air than between water and air; and, ſince the ſpirit evaporates much faſter than the water, the *evaporation* of fluids ſeem to ariſe from an attractive force between their particles and thoſe of air. Finally, after diſſolving a body in any proper menſtruum, if another be added that has a greater affinity to the menſtruum than the firſt, this will be diſſolved, and the firſt will be precipitated; and in the ſame manner, any fluid will let go the air which it contains on the addition of another body to which it has a greater affinity than it has to the air; from which fact it may be inferred, that the air, imbibed by any fluid, is, properly ſpeaking diſſolved in that fluid, and therefore, that any fluid which evaporates, or is imbibed by the air, is alſo, properly ſpeaking, diſſolved in air. Dr. Hamilton, having evinced the agreement between ſolution and *evaporation*, concludes, that *evaporation* is nothing more than a gradual ſolution of water in air, produced and promoted by attraction, heat, and motion, juſt as other ſolutions are effected.

In order to account for the aſcent of aqueous vapours into the atmoſphere, this ingenious writer obſerves, that the loweſt part of the air being preſſed by the weight of the upper againſt the ſurface of the water, and continually rubbing upon it by its motion, attracts and diſſolves thoſe particles with which it is in contact, and ſeparates them from the reſt of the water. And ſince the cauſe of ſolution in this caſe is the ſtronger attraction of the particles of water towards the air than towards each other, thoſe that are already diſſolved and taken up will be ſtill farther raiſed by the attraction of the dry air which lies over them, and thus will diffuſe themſelves, riſing gradually higher and higher, and thereby leave the loweſt air, not ſo much ſaturated but that it will ſtill be able to diſſolve and take up freſh particles of water; which proceſs is greatly promoted by the motion of the wind. When the vapours are thus raiſed and carried by the winds into the higher and colder parts of the atmoſphere, ſome of them will coaleſce into ſmall particles, which ſlightly attracting each other, and being intermixed with air will form CLOUDS; and theſe clouds will float at different heights, according to the quantity of vapour borne up, and the degree of heat in the upper parts of the atmoſphere. Thus clouds are generally higher in ſummer than in winter. When the clouds are much increaſed by a continual addition of vapours, and their particles are driven cloſe together by the force of the winds, they will run into drops heavy enough to fall down in RAIN. If the clouds are frozen before their particles are gathered into drops, ſmall pieces of them being condenſed and made heavier by the cold, fall down in thin flakes of SNOW. If the particles are formed into drops before

they are frozen, they become HAIL-*stones*. When the air is replete with vapours, and a cold breeze springs up which checks the folution of them, clouds are formed in the lower parts of the atmofphere, and compofe a MIST or FOG, which ufually happens in a cold morning, and is difperfed when the fun has warmed the air, and made it capable of diffolving thefe watery particles. Southerly winds generally bring rain, becaufe being commonly warm and replete with aqueous vapours, they are cooled by paffing into a colder climate; and therefore part with fome of them, and fuffer them to precipitate in rain: whereas northerly winds, bring cold, and acquiring additional heat by coming into a warmer climate, are ready to diffolve more vapour than they before contained; and therefore, by long continuance, they are dry and parching, and ufually attended with *fair* weather.

Changes of the air, with refpect to its denfity and rarity, as well as its heat and cold, will produce contrary effects in the folution of water and the confequent afcent or fall of vapours. Several experiments prove, that air, when rarefied, cannot keep as much water diffolved as it does in a more condenfed ftate; and therefore, when the atmofphere is faturated with water, and changes from a denfer to a rarer ftate, the higher and colder parts of it will let go fome of the water before diffolved, form new clouds, and difpofe them to fall down in rain; but a change from a rarer to a denfer ftate will ftop the precipitation of the water, and enable the air to diffolve either in whole or in part, fome of thofe clouds that were formed before, and render their particles lefs apt to run into drops and fall down in rain; on this account, we generally find, that the rarefied and condenfed ftates of the atmofphere are refpectively attended with rain or fair weather. See more on this fubject in the Phil. Tranf. vol. lv. art. 23. p. 146, &c. or Hamilton's Philofophical Eflays, 8vo. 1766. p. 33, &c.

Dr. Halley furnifhes us with fome experiments of the quantity or meafure of the *evaporation* of water. The refult is contained in the following articles.

1. That water falted to about the fame degree as falt-water, and expofed to a heat equal to that of a fummer's day, did, from a circular furface of about eight inches diameter, evaporate at the rate of fix ounces in 24 hours. Whence, by a calculus, he finds that the thicknefs of the pellicle or fkin of water, evaporated in 2 hours, was the 53d part of an inch; but, for a round number, he fuppofes it only a 60th part; and argues thence, that if water as warm as the air in fummer evaporates the thicknefs of one 60th part of an inch in 2 hours from its whole furface; in 12 hours it will evaporate the 10th of an inch: which quantity, he obferves, will be found abundantly fufficient to furnifh all the rains, fprings, dews, &c.

In effect, on this principle, every 10 fquare inches of the furface of the water yield in vapour *per diem* a cubic inch of water; and each fquare foot half a wine pint; every fpace of 4 feet fquare, a gallon; a mile fquare, 6914 tons; and a fquare degree of 69 Engliſh miles will evaporate 33 millions of tons a day; and the whole Mediterranean, computed to contain 160 fquare degrees at leaft 5280 millions of tons. Phil. Tranf. N° 189 or Abridg. vol. ii. p. 108, &c.

2. A furface of 8 fquare inches, evaporated purely by the natural warmth of the weather without either wind or fun, in the courfe of a whole year, 16292 grains of water, or 64 cubic inches; conſequently the depth of water thus evaporated in one year amounts to 8 inches. But this being too little to anfwer the experiments of the French, who found that it rained 19 inches of water in one year at Paris; or thofe of Mr. Townley, who found the annual quantity of rain in Lancafhire, above 40 inches; he concludes, that the fun and wind contribute more to *evaporation* than any internal heat or agitation of the water.

It has fince been difcovered, that there was a fource of error in Mr. Townley's experiments, with which the world was not at that time acquainted: his rain-gage was fixed 10 yards above the furface of the earth; but Dr. Heberden has found, that a rain-gage fixed below the top of a houſe received above a *fifth* part more rain than another of the fame fize above the top of the fame houſe; and that there fell upon Weſtminſter Abbey not much above one-half of that which fell in the fame fpace below the tops of the houſes; and by ſeveral experiments made by Dr. Dobſon of Liverpool, it appears, that the quantity of rain received in a veſſel placed on the ground exceeded that received by another of the ſame dimenſions 18 yards higher more than one-third, and leſs than one-half. Phil. Tranſ. vol. lix. art. 47. and vol. lxvii. art. 13. p. 260.

With regard to the cauſe of this difference, it may be obſerved, that as in chemical precipitations a greater portion of the precipitating ſubſtance will be received on the real bottom of a veſſel containing the ſolution than on a ſuppoſed falſe bottom placed any where above it, and that in proportion to its height above the real bottom; ſo a greater quantity of water, conſidering rain as a precipitation of water before diſſolved in air, ought, on parting with its former ſolvent, to fall on the ſurface of the earth, than on an imaginary horizontal plane of the ſame dimenſions above it; and though the caſes are not exactly parallel, yet the drops of rain in their deſcent muſt be ſomewhat increaſed either in number or ſize; partly by ſucceſſively impinging on the aqueous particles contained in the air through which they paſs, and by attracting others in virtue of their being poſſeſſed of a different electricity; and partly by the ſpontaneous ſeparation and precipitation of that moiſture, which is known to be contained in conſiderable quantities in the air at all times, and the appearance of which, dripping down the walls of our houſes, &c. is one of the popular ſigns of approaching rain. Monthly Review, vol. xliv. p. 322. Dr. Dobſon ſtates the annual *evaporation* at Liverpool, taking the medium of 4 years at 36.58 inches. Dr. Halley fixes the annual *evaporation* of London at 48 inches. See Phil. Tranſ. vol. lxvii. part i. p. 252.

3. The effect of the wind is very conſiderable, on a double account; for the ſame obſervations ſhew a very odd quality in the vapours of water, viz. that of adhering and hanging to the ſurface that exhaled them, which they clothe as it were with a fleece of vaporous air; which once inveſting the vapour, it thenceforward rifes in much leſs quantity. Whence, the quantity of water loſt in 24 hours, when the air was very ſtill from wind, was very ſmall, in proportion to what went away when there was a ſtrong gale of wind abroad to diſſipate the fleece, and make room for the emiſſion of vapour; and this, even though the experiment was made in a place as cloſe from the wind as could be contrived.

Add, that this fleece of water hanging on the ſurface of waters in ſtill weather is the occaſion of very ſtrange appearances, by the refraction of the vapour's differing from and exceeding that of common air; whence every thing appears raiſed, as houſes like ſteeples, ſhips as on land above the water, the land raiſed, and as it were lifted from the ſea, &c.

4. The ſame experiments ſhew, that the *evaporation* in May, June, July, and Auguſt, which are nearly equal, are about three times as great as thoſe in the months of November, December, January, and February. Phil. Tranſ. N° 212. or Abr. ani. ii. p. 110, &c.

Dr. Brownrigg, in his Art of making Common Salt, p. 189, fixes the *evaporation* of ſome parts of England at 73.8 inches during the months of May, June, July, and Auguſt; and the *evaporation* of the whole year at more than 140 inches. The *evaporation* of the four ſummer months at Liverpool, on a medium of four years, was found to be only 18.88 inches. Dr. Hales calculates the greateſt annual *evaporation* from the ſurface of the earth in England at 6.66 inches; and therefore the annual *evaporation* from a ſurface of water, is to the annual *evaporation* from the ſurface of the earth in Liverpool as 36 to 6, or as 6 to 1. Phil. Tranſ. vol. lxvii. ubi ſupra.

EVAPORATION, in *Pharmacy*, *Chemiſtry*, &c. denotes an operation by which the more aqueous and volatile parts of fluids are ſpent, or driven away in ſteam, ſo as to leave the remaining part ſtronger, or of a higher conſiſtence than before.

Evaporation is effected by ſetting a liquor over a gentle heat, to carry off the moſt fluid and volatile parts, without leſſening the quantity of the other matters with which the liquor is impregnated.

The veſſels uſed for this purpoſe are baſons, teſts, or crucibles, which are made of glaſs, metal, or earth, according to the nature of the bodies on which the operation is to be performed. They are flat, ſhallow, and wide, ſo that the body from which the *evaporation* is to be made may preſent a large ſurface to the air. In all *evaporations* the degree of heat ought to be proportioned to the volatility of the ſubſtance to be evaporated, and to the degree of fixity of the ſubſtance intended to be left, and of its adheſion to the volatile parts. In ſome caſes, as in obtaining oil from rectified ſpirit of wine and æther, the liquors ought to be evaporated upon the ſurface of water in open air, without any other heat than that of the atmoſphere; in others, when the part to be evaporated is not very volatile, and when the remaining ſubſtance is very fixed, and does not adhere much to the volatile part, as in the purification of gold by antimony, a ſtrong heat may be applied, and a current of air directed upon the ſurface of the body. *Macquer.*

EVASION, *evaſio*, in *Law*, is uſed for any ſubtile endeavour to ſet aſide truth, or to eſcape the puniſhment of the law, which will not be endured. Thus, if a perſon ſays to another that he will not ſtrike him, but will

give

give him a pot of ale to ſtrike him firſt: and accordingly he ſtriker, the returning of it is puniſhable; and if the perſon firſt ſtriking be killed, it is murder; for no man ſhall evade the juſtice of the law by ſuch a pretence to cover his malice. 1 Hawk. P. C. 81.

EVATES, a branch or diviſion of the ancient Celtic philoſophers the DRUIDS.

Strabo diſtributes the philoſophers among the Britons and Gauls into three ſects; τριτ'ω, *Bardi*, Ουάτεις, *Evates*, and Δρυίδαι, *Druidæ*. He adds, that the *Bardi* were poets and muſicians: the *Evates*, priests and naturaliſts; and the *Druidæ*, moraliſts as well as naturaliſts. But Marcellinus, Voſſius, and Hornius, reduce them all to two ſects, viz. *Bardi* and *Druidæ*. Laſtly, Ceſar, lib. vi. comprehends them all under the name of *Druidæ*.

The *Evates* or *Vates* of Strabo might probably be what other authors, and particularly Ammian. Marcellin. calls *Eubages*; but Mr. Bouche, in his Hiſt. de Provence, lib. ii. chap. 2. diſtinguiſhes between them. The *Vates*, he ſays, were ſuch as took care of the ſacrifices and other ceremonies of religion; and the *Eubages*, thoſe who ſpent their time in the ſearch and contemplation of the great myſteries of nature.

EUBAGES, an order of prieſts or philoſophers among the ancient Celtæ or Gauls. Chorier takes the *Eubages* to be the ſame with the *Druids* and *Saronidæ* of Diodorus. Others will have the *Eubages* to be thoſe whom Strabo, lib. iv. p. 197. calls Ουάτεις, *Evates*, or *Vates*, on which principle there is room to conjecture, that the word ſhould be written Ουβάτεις, it being eaſy to miſtake a T for a B.

Be this as it will, the *Eubages* appear to have been a different order from the *Druids*. See DRUID.

EUCHARIST, *Euchariſtia*, the ſacrament of the Supper, or a participation of the body and blood of Chriſt, under the ſpecies or figures of bread and wine. See COMMUNION, SACRAMENT, SPECIES, TRANSUBSTANTIATION, and CONSUBSTANTIATION.

The word is in original Greek, Ευχαριστια, literally imports *thanksgiving*, being formed of ευ, *bene*, *well*, and χαρις, *gratia*, *thanks*.

EUCHITES, or EUCHITÆ, a ſect of ancient heretics, who were firſt formed into a religious body towards the end of the fourth century, though their doctrine and diſcipline ſubſiſted in Syria, Egypt, and other eaſtern countries before the birth of Chriſt; they were thus called becauſe they prayed without ceaſing, imagining that prayer alone was ſufficient to ſave them.

Their great foundation was thoſe words of St. Paul, Epiſt. i. to the Theſſalonians, chap. v. ver. 17. *pray without ceaſing*.

The word is formed of the Greek ευχη, *prayer*, whence ευχεται, the ſame with the Latin, *precatores*, *prayers*. They were alſo called *Euchonfiaſtæ* and *Maſſalians*, a term of Hebrew origin, denoting the ſame as *Euchites*.

The *Euchites* were a ſort of myſtics who imagined, according to the oriental notion, that two ſouls reſided in man, the one good, and the other evil; and who were zealous in expelling the evil ſoul or demon, and haſtening the return of the good ſpirit of God, by contemplation, prayer, and ſinging of hymns. They alſo embraced the opinions nearly reſembling the Manichean doctrine, and which they derived from the tenets of the oriental philoſophy. The ſame denomination was uſed in the twelfth century, to denote certain fanatics who infeſted the Greek and Eaſtern churches, and who were charged with believing a double Trinity, rejecting wedlock, abſtaining from fleſh, treating with contempt the ſacraments of Baptiſm and the Lord's Supper, and the various branches of external worſhip, and placing the eſſence of religion ſolely in external prayer, and maintaining the efficacy of perpetual ſupplications to the Supreme Being for expelling an evil being or genius, which dwelt in the breaſt of every mortal. This ſect is ſaid to have been founded by a perſon called Lucopetrus, whoſe chief diſciple was named Tychicus. By degrees it became a general and invidious appellation for perſons of eminent piety and zeal for genuine Chriſtianity, who oppoſed the vicious practices and inſolent tyranny of the prieſthood; much in the ſame manner as the Latins comprehended all the adverſaries of the Roman pontiff under the general terms of WALDENSES and ALBIGENSES. Moſh. Eccl. Hiſt. Eng. edit. 8vo. vol. i. p. 350. and vol. ii. p. 441.

St Cyril of Alexandria, in one of his letters, takes occaſion to cenſure ſeveral monks in Egypt, who, under pretence of reſigning themſelves wholly to prayer, led a lazy, ſcandalous life. A cenſure likewiſe applicable to monaſteries in general.

EUCHOLOGIUM, Ευχολογιον, a Greek term, ſignifying literally, *a diſcourſe on prayer*.

The word is formed of ευχη, *prayer*, and λογος *diſcourſe*.

The *Euchologium* is properly the Greek RITUAL, wherein are preſcribed the order and manner of every thing relating to the order and adminiſtration of their ceremonies, ſacraments, ordinations, &c.

Fa. Goar has given us an edition of the Greek *Euchologium* in Greek and Latin, with notes, at Paris.

EUCHYMIA, from ευ, *good*, and χυμος, *juice*, in *Medicine*, a good temper of the blood, or other juices and fluids in an animal body.

EUCLABRIS, in *Antiquity*, a table whereon the ſlaughtered victim was ſpread, in order to have its inteſtines carefully inſpected. It was from this table that the veſſels uſed in ſacrifices were called *euclabria*.

EUCRASY, of ευ, *well*, and κρασις, *temperature*, an agreeable, well-proportioned mixture of qualities, whereby a body is ſaid to be in good order, and diſpoſed for a good ſtate of health.

EUDIOMETER, in *Pneumatics*, is an inſtrument lately invented, in conſequence of the experiments and diſcoveries of Dr. Prieſtley, for determining the ſalubrity of different kinds of AIR. The name is formed of ευδια, ſignifying the *good quality of air*, derived from ευ, *good*, and δια, denoting, in compoſition a *medium*, and μετρον, *I meaſure*.

The reader will find under the article AIR, *nitrous*, an account of the principle on which the conſtruction of theſe inſtruments depends. Dr. Prieſtley, having diſcovered that when nitrous air is mixed with any other air, their original bulk is diminiſhed; and that the diminution is nearly, if not exactly, in proportion to its ſalubrity, was led to adopt nitrous air as a true teſt of the purity of reſpirable air; and nothing more ſeemed to be neceſſary than an eaſy, expeditious, and accurate method of eſtimating the degree of diminution in different caſes; and for this purpoſe the *eudiometer* was contrived. The diſcovery of Dr. Prieſtley was announced to the public in the year 1778; and the abbé Fontana and the chevalier Landriani, both of Italy, were the firſt who availed themſelves of this diſcovery in the conſtruction of *eudiometers*. One of theſe inſtruments, invented by Landriani, conſiſts of a glaſs tube ground to a cylindrical veſſel, with two glaſs cocks and a ſmall baſon, all fitted in a wooden frame. In this inſtrument quickſilver is uſed inſtead of water; and that part of it which replaces the bulk loſt by the diminution of the two mixed airs, is conducted either through a kind of glaſs ſyphon, or through the capillary holes of a glaſs funnel; ſo that by its fall the whole mixture of the two kinds of air is more readily made. Dr. Falconer of Bath accurately alluded a glaſs tube, in order to exhibit the quantity of diminution produced by the mixture of nitrous air with air of another kind, agreeably to the method uſed by Dr. Prieſtley in the purſuit of this curious diſcovery. See EFFLUVIA. Mr. J. H. de Magellan, F. R. S. has deſcribed three different *eudiometers* of his own contrivance. One of theſe conſiſts of the following parts, viz. a glaſs tube *m n d*, (*ſee Tab.* I. *Pneumatics*, *fig.* 8.) about 12 or 15 inches long, and of an equal diameter, with a ground glaſs ſtopple *m* a veſſel *c*, the neck of which is ground air-tight to the lower end *d* of the tube; and two equal phials, *a* and *b*, whoſe necks are alſo ground air-tight to the reſpective mouths of the veſſel *c*; both theſe veſſels contain nearly as much as the whole tube *m n d*. There is alſo a ſliding braſs ring *n*, which ſlides in the tube *n d*, and may be made tight at pleaſure by a finger-ſcrew; and laſtly, a ruler *g*, either of braſs or of wood, repreſented *fig* 9. which is divided into equal parts, and indicates the contents of both the phials *a* and *b* when thrown into the tube, by the number of parts which is engraved or ſtamped about the middle of it. The two bent pieces of braſs *z*, *t*, ſerve to hold it eaſily by the ſide of the tube *n d*, (*fig.* 10. and *fig.* 11.) keeping it cloſe to the neck *n* by the notch *i*. In uſing this inſtrument, it will be convenient to have a tall glaſs receiver like that repreſented *fig.* 10. or a tube or trough *fig.* 11. made with ſtraight boards of elm-wood one inch thick; the inſide dimenſions here 25 inches long, 13½ wide, and 15 deep: the two end boards, *a d* and *e f*, are fitted into a groove cut in the other three boards: it ſhould be daubed with thick white paint as a cement, for retaining the water, and the whole faſtened with nails from the outſide. The ſhelf *w x n e* is 8 inches wide, and 2 inches thick, in which are 3 holes of 3 tenths of an inch diameter, with as many ſeparate cavities underneath, ſo as to ſerve like ſo many funnels; or a glaſs funnel *s* cemented to the middle hole *n* is equally convenient. This ſhelf is ſupported by 4 metallic hooks *V w x n*, which may be raiſed or lowered at pleaſure by means of wooden wedges. A trough of this kind is the moſt commodious for experiments on different kinds of air.

Let ſuch a trough or tub be nearly filled with water, take out the ſtopple *m* of the *eudiometer* and fill it with water in the poſition exhibited *fig.* 8. or *fig.* 11. then cloſe

close it with the stopple *m*, without leaving any air in the inside; and put the lower part *c* under the surface of the water in the tub. *fig.* 11. in the position there represented. Let the phial *a*, filled with water, be kept with its mouth downwards, under the surface of the water, and filled with that air, the salubrity of which it is required to ascertain. This is done either by putting the phial *a* on the shelf *n o* of the tub, *fig.* 11. and throwing the air into the glass funnel *l*, which is there cemented to the shelf; or by holding in the left hand the same phial *a*, together with a glass funnel without a pipe applied to the mouth of the phial, whilst the air is poured with the right hand into it. But lest the heat of the hand should produce any considerable expansion in the air, the glass funnel may be held close to the mouth of the phials by wooden tongs with bent wires *s s*, *fig.* 12. unless they are made with a solid lump at their bottoms as they are here represented. If a glass bottle with a ground glass stopple be filled with water or mercury, and emptied in the place whose atmospherical air is to be tried, it will be filled with that air; and being closed with the glass stopple, may be carried to any distant place, in order to determine its comparative salubrity. When the phial *a* is filled with air in the manner already described, it is put moderately tight into the mouth of the vessel *c*; and for greater security against accidents, the necks of the phials *a*, *b*, and of the vessel *c*, as well as the glass stopple *m*, are always rubbed with tallow previously to every experiment. Then take the phial *b* filled with water, and by the same process fill it with nitrous air, and replace this phial *b* in the other mouth of the vessel *c*. Let the *eudiometer* be carefully inverted, so that the two phials may be downwards as exhibited in *fig.* 10. by this operation the two kinds of air come up to *s* from the phials *a*, *b*, and thus are mixed together: when this is done, dip the *eudiometer* in the water of the trough, *fig.* 11. leaving the mouth of the instrument above its surface; so that no more water may enter into it than it had at first. Then attentively observe the moment when the mixture *s*, (*fig.* 10.) of the two kinds of air comes to its greatest diminution; after which, as Mr. Magellan has observed, its bulk will begin to increase again: for this purpose slide down the brass ring *n* of the instrument as the surface of the water in the tube falls; and when this becomes stationary, which it will do in a few minutes, if the nitrous air has a proper strength, we shall have the greatest diminution. Then fill up the whole tube of the *eudiometer* with water, shut it up with the stopple *m*, and incline the top of the instrument forwards till the air comes from *s* up to the top *o* of the tube; keep the lower part of the instrument dipped in the water; take off the glass vessel *c* with the two phials *a*, *b*, and raise or lower the tube of the *eudiometer* so as to see the surface of the water in the inside even with that on the outside, which mark by sliding to it the brass ring *n*. Or apply the ruler (*fig.* 9.) to the side of the *eudiometer* whilst it is immersed in the water of the trough, and thus you will see the true dimension of the remaining bulk of the two kinds of air already diminished. The number marked about the middle of this ruler, e. g. ** = 96, denotes that the contents of both phials *a* and *b* are equal to 96 divisions of the ruler when put into the tube of that *eudiometer*; or they are equal to a solid cylinder, as thick as the inside of the glass tube, and whose length is 96 divisions of the ruler divided into tenths of an inch. When e. g. the remaining bulk of mixed air corresponds to the 56th division of the ruler, it shews that out of 96 parts only 40 (= 96 − 56) have been lost or contracted; and in this case the wholesomeness of that air called A will be 42. If another equal quantity of different air called B, be tried by the same *eudiometer*, and its residuum be equal to 60 parts of the same ruler, the relative salubrity of the air B will be to that of A, as 36 (= 96 − 60) to 40. But if the air B had been tried by another *eudiometer*, whose proportional dimensions marked about the middle of its ruler, were ** = 108, then the comparative salubrity of these two kinds of air A and B would be in the compound ratio of $\frac{36}{108}$ to $\frac{40}{96}$, $\frac{36 \times 96}{108 \times 96}$ to $\frac{40 \times 108}{108 \times 96}$, 3456 to 4320 = 4 to 5; or the wholesomeness of the air B would be to that of A as 54 to 67½. If the operator be provided with a tall glass receiver, as *fig.* 10. he need only dip the *eudiometer* inverted into the water contained in the vessel *P S q t*; put the two kinds of air into the phials *a* and *b* in the manner already directed; turn the instrument upright as in *fig.* 10. and finish the process in the method just described: but he should take care that every part of the process be conducted in the same temperature, since air is apt to expand or contract by heat and cold; and therefore, he should keep a good thermometer as *K*, suspended by the wire *y r*, and immersed in the water of the glass vessel *fg.* 10. or in the trough *fig.* 11. during the progress of these experiments.

Another *eudiometer* of a more simple kind consists of a straight glass tube *x m* (*fig.* 13.) of an uniform diameter, about two or three feet long, with a large ball *t*, and a glass stopple *m* fitted air-tight to the mouth *x*, which should be wide open in the shape of a funnel. There is also a small siphon *k l*, *fig.* 14. with a brass ring *r*; a small phial *n*, *fig.* 15. the contents of which may occupy a third part of the ball *t*, or half the length of the glass tube *m x*: to this instrument also belongs a ruler divided and stamped, like that already described. When this instrument is used it is filled with water, and placed in a vertical position with the mouth *x* under the surface of the water in a tub or trough: the phial *n* (*fig.* 15.) is filled first with nitrous air, which is thrown into the tube either by a glass funnel applied to its mouth, or when its mouth is wide enough, without any funnel: the phial is next filled with the air to be tried, which is thrown into the same tube. Then the siphon (*fig.* 13.) is immediately applied to the mouth of the *eudiometer* under the surface of the water; some of which is to be poured into it. Having watched the stationary moment of the greatest diminution of the mixed air at *r* by means of the ring *x*, at that moment remove the siphon *k l*, and lay the *eudiometer* for some minutes under water in a horizontal position, or nearly so, that no part of the inclosed air may escape; shut the mouth *x* with the glass stopple *m*, and invert the instrument with the mouth *x* upwards. Lastly, measure the space occupied by the residuum of the diminished air, by applying to its side the divided ruler or scale, and estimate the result as before. *Eudiometers* are used with water or with quicksilver; but the latter suffering a sensible action from the contact with nitrous air, and being both heavier and denser than water, is less eligible than the former. An instrument of this kind is capable of being applied to important and useful purposes in determining the comparative salubrity of the air in different climates and situations. See Magellan's Letter to Dr. Priestley, containing the Description of a Glass Apparatus, &c. and of New *Eudiometers*, &c. 1777. p. 15—47. and Priestley's Exp. and Obs. on Air, vol. iii. Preface and Appendix. See also an account of easy methods of measuring the diminution of bulk, occasioned by the mixture of common and nitrous air, by Dr. Ingenhousz, in the Phil. Transf. vol. lxvi. part i. art. 15. For an account of a new *eudiometer* by Mr. Cavendish, see Phil. Transf. vol. lxxiii. part i. p. 106. See Effluvia.

EUDOXIANS, a party or sect of heretics in the fourth century, so denominated from their leader Eudoxius, patriarch of Antioch and Constantinople, a great defender of the Arian doctrine.

The *Eudoxians* adhered to the errors of the Arians and Eunomians, maintaining that the Son was created out of nothing; that he had a will distinct and different from that of the Father, &c.

EVE. See Vigil.

EVECTION, is used by some astronomers for the libration of the moon. See Libration.

The term *evection* is used by some astronomers to denote that equation of the moon's motion, which is proportional to the sine of double the distance of the moon from the sun, diminished by the moon's anomaly: this equation is not yet accurately determined; some state it at 1° 30′, others at 1° 16′, &c. It is the greatest of all the moon's equations, except the Equation of the centre.

EVEN *foot*, in *Poetry*. See Foot.

Even *number*, is that which may be divided into two equal parts or moieties. See Number.

EVENING *star*. See Vesper.

EVENLY *even number*, is that which is exactly divisible by an even number taken an even number of times; such is 32, since it is divisible by 8, taken four times.

Evenly *odd number*, is that which an even number measures by an odd one; as 30, which is measured by 6, taken five times.

EVERARDS *sliding rule*. See Sliding.

EVERGETES, Ευεργετης, a Greek term, signifying *benefactor*, being formed of ευ, *bene*, well, and εργον, *opus*, *work*. It is still retained in our language by way of addition or epithet given to two princes or kings of Syria and Egypt, who succeeded Alexander. Thus we say Ptolemy *Evergetes*, king of Egypt, Antiochus *Evergetes* king of Syria.

EVER GREENS, a class of perennials, which continue their verdure, leaves, &c. all the year.

Of these our gardeners reckon twelve, which are peculiarly fit for English air, viz. the alaternus, arbutus, bay-tree, box-tree, holly, juniper, laurustinus, phyllirea, pyracantha, or *evergreen* thorn, Italian green privet, and the yew-tree.

EVERLASTING *fire*. See ETERNAL *fire*.

EVERLASTING *pea*. See *Climbing* VETCH.

EVERRATOR, derived from *ex* and *verro*, *I cleanse*, in *Antiquity*, an officer who was obliged in a solemn manner to cleanse such houses as were defiled by dead bodies, called *domus funesta*.

EVERRICULUM, in *Surgery*, the name given by Paré to a sort of speculum or sponge, used to clear the bladder of gravel and grumes of blood left in it after the operation of lithotomy.

EVES-DROPPERS, in *Law*. See EAVES-*droppers*.

EUEXIA, from *eu*, *well*, and *ἕξις*, *habit*, in *Medicine*, a good habit or habit of body.

EUGENIA, in *Botany*, the name given by Micheli and Linnæus to a genus of plants of the *icosandria monogynia* class, described in the Hortus Malabaricus. The characters are these: the perianthium consists of one leaf divided into four oblong, acute, concave, and permanent segments; the flower is composed of four oblong and hollow obtuse petals, twice as large as the segments of the cup; the stamina are a great number of slender filaments inserted in the cup, and reaching the length of the flower; the anthera are small; the germen is of a turbinated form, and is placed below the cup; the style is simple, and of the length of the stamina; the stigma is simple; the fruit is a coronated drupe of a quadrangular figure, containing only one cell, in which is contained a large, roundish, and smooth nut. There are six species.

EVICTION, from *evinco*, *I overcome*, in *Law*, signifies a recovery of lands or tenements by law.

EVIDENCE, a quality in things whereby they become visible and apparent to the eyes, either of the body or the mind.

The Schoolmen distinguish *evidence* into *formal* and *objective*.

EVIDENCE, *formal*, is the act of the intellect, considered as clear and distinct.

EVIDENCE, *objective*, consists in the clearness and perspicuity of the object; or it is the object itself so constituted as it may be clearly and distinctly known.

Others divide *evidence* into *moral*, *physical*, and *metaphysical*. A thing is said to be *morally evident*, so far as we have a distinct notion or knowledge thereof, by unexceptionable witnesses; *physically*, so far as natural sense and reason, pointing out any thing, convinces us thereof; *metaphysically*, when we enter fully and clearly into the essence of any thing.

Evidence is the essential and infallible character or criterion of truth, and is that in effect which with us constitutes truth.

If *evidence* should be found in propositions that are false, we should be compelled into error, since the assent we give to *evidence* is necessary: whence would follow this impious position, that God who made us is the author of our errors, as he has constituted us so as to put us under a necessity of falling into them.

It may be added, that as we necessarily love truth and hate error, it seems inconsistent with the nature of a beneficent being to form us with a love of what we could not obtain, or not know whether we did obtain it or not; besides, that if we should err in things that are evident, as well as in those that are not so, we should sometimes find contradictions in *evident* propositions, as we commonly do in things that are obscure.

Evidence, therefore, must be allowed the mark of truth; and those things must be allowed true which carry with them such a degree of *evidence* as obliges us to assent to them. Whatever we see *evidently* agreeable to things, where of we speak, that we must acknowledge to be true.

The Epicureans allow of no other *evidence* but that of sense, or that arising from sense, it being a fundamental principle with them, that sense is the first and primary criterion of all truth.

By *evidence of sense*, they mean that species or image exhibited by the sense or primary; which, when all impediments to a full judging, as distance, motion, medium, &c. are removed, cannot be contradicted or falsified; wherefore, the question being put, whether or no a thing be such as it appears; the answer is not to be given, till it has been tried and examined in all the ways, and by all the senses, that it can be an object of. See ERROR.

There are certainly other superior and less fallible sources or grounds of *evidence* than sense: such is that inward consciousness by which we learn what belongs to the mind; or that which Mr. Locke calls reflection; of which such are intelligence, intuition, and common sense, principally relating to these abstracted, or other propositions that carry their own *evidence* with them, and admit no doubt about them; whence we derive our assent to propositions called axioms and maxims; such is also reasoning, whereby we infer one truth from others by natural and just methods of argument, whence results science; such is likewise the testimony of others, on which we found the *evidence of* FAITH, to which we may also add inspiration, or that impression made on the mind by God himself, which gives a convincing and indubitable *evidence* of the truth of any proposition, undistilled to others, either by prophecy or miracles. Watts's Logick, part ii. chap. ii. § 9.

By this considering the various sources whence our perception and belief of any truth are derived, we may be led to distinguish *evidence*, into INTUITIVE and DEDUCTIVE, and that founded on TESTIMONY. See Campbell's Phil. of Rhet. book i. chap. 5.

The *evidences* of the Christian religion are distinguished into two kinds, the direct and collateral: the direct *evidences* are external and internal; the external are miracles and prophecy; the internal *evidence* is deduced from its excellence, considered in reference to the main and principal end of CHRISTIANITY. Whatever does not either belong to its excellence considered in this light, or fall under the head of miracles wrought on purpose to attest it, or of prophecies fulfilled, and yet affords a proof or any real presumption of its truth and divinity, is a collateral *evidence* for it. All the collateral *evidences* of the truth of Christianity are in one sense internal *evidences*, because they all arise from some particulars in the nature of this religion, from some circumstances which have attended its reception or sprung from it, or from some remarkable facts connected with it, and related in the Gospel history. Of this kind is the argument deduced from its great efficacy at its first appearance, in banishing polytheism, idolatry, superstition, and the arts of magic; in softening the rigour of despotism, introducing moderation into government, excluding many inconveniencies civil laws once generally prevalent, giving rise to others of a very happy tendency, refining the laws of war, humanizing the manners and improving the customs of nations, and reforming the temper and conduct of those who embraced it.

Another class of collateral arguments for the truth of the Christian religion, arises from particulars in its nature or effects produced by it, or from facts in the Gospel history, which cannot be at all accounted for but on the supposition of a Divine original, or which are, at least, most naturally explicable on that supposition. To this class may be referred those presumptive arguments deduced from the character of Jesus, so exalted, and yet so uniformly supported; the nature of his last discourses with his disciples; the character of some of his apostles; that of Judas the traitor; the causes effects among Christians in the apostolic age; and the method used by Christ and his apostles, of referring their claims to the impartial inquiries of men. Other collateral arguments have an affinity to the external *evidences* of Christianity: such are those derived from the miraculous conversion of the apostle Paul and his subsequent conduct, from the character of the man of sin foretold by Paul; from the quick and extensive propagation of the Gospel; from the continuance and present state of the nation of the Jews. Some of these arguments have an immediate relation to the proof of Christianity from prophecies; others are related to the proof from miracles. Other arguments have an equal relation to the internal and external *evidence* of Christianity; such as that deduced from the manner in which Christ and his apostles proposed the *evidences* of their mission, and the advantage they have gained in consequence of the opposition and scrutiny of unbelievers. See on this subject Lord Lyttelton's Observations on the Conversion and Apostleship of St Paul, Duchal's Presumptive Arguments for the Truth of the Christian Religion, and Gerard's Dissertation on the Genius and *Evidences* of Christianity.

EVIDENCE, in *Law*, is any proof, whether by testimony of men on oath, or by writings and records; the former called *parol evidence*, and the latter *written evidence*.

It is thus called, because the point in issue is hereby made *evident* to the jury.

With regard to parol *evidence*, or witnesses, we may observe in general, that a party interested in a suit, or a wife for or against her husband, a husband against his wife, except in cases of treason, an alien, infidel, persons *non sanæ memoriæ*, those that are attainted of conspiracy, or in a præmunire upon that. 5 Eliz. cap. 1. Popish recusants convict on that. 3 Jac. I. cap 5. persons convicted of felony, perjury, &c. those who by judgment have stood on the pillory, or been whipped, whilst the judgment is in force, are disabled from giving *evidence*: but kinsmen, though ever so near, tenants, servants, masters, attornies for their clients, one of the jurors upon trial, and all others that are not infamous, who want not understanding, or are no parties in interest, may give *evidence* in a cause, though the credit of servants is left to the jury. If an action is brought against

against many persons for taking of goods, one of them may be admitted as an *evidence* against the reſt.

And in criminal *cases*, as of robbery on the highway, in an action againſt the hundred, and rapes of women, &c. a man or woman may be an *evidence* in their own caſe: ſo likewiſe in private notorious cheats, where none elſe can be witneſs of the circumſtances of the fact but he who ſuffers. When perſons that are competent witneſſes are ſerved with a writ of *ſubpœna ad teſtificandum*, they are bound to appear at the trial on pain of 10*l.* to be forfeited to the king, to which the ſtat. 5 Eliz. cap. 9 has added a penalty of 10*l.* to the party aggrieved, and damages equivalent to the loſs ſuſtained by want of their *evidence*: but no witneſs, unleſs his reaſonable expences be tendered him, is bound to appear at all; nor if he appears, is he bound to give *evidence* till ſuch charges are actually paid him, except he reſides within the bills of mortality, and is ſummoned to give *evidence* within the ſame.

One credible witneſs is ſufficient *evidence* to a *jury* of any ſingle fact in all civil actions; but in caſes of high *treaſon*, petit treaſon, and miſpriſion of treaſon, by ſtatutes 1 Edw VI. cap. 12. 5 and 6 Edw. VI. cap. 11. and 1 and 2 Ph. and Mar. cap. 10. *two* lawful witneſſes are required to convict a priſoner, except in caſes of coining and counterfeiting the ſeals, or unleſs the party ſhall willingly and without violence confeſs the fame: and by ſtat. 7 W. III. cap. 3. the confeſſion of the priſoner muſt be in open court; and both witneſſes muſt be to the ſame overt act of treaſon, or one to one overt act and the other to another overt act of the ſame ſpecies of treaſon. Baron Monteſquieu, indeed, *lays it down for a rule*, Spirit of *Laws*, book xii. chap. 3. that thoſe laws which condemn a man to death *in any caſe* on the depoſition of a ſingle witneſs, are fatal to liberty.

All *evidence* is to be given in open court, in the preſence of the parties, their attornies, the counſel and all by-ſtanders, and before the judge and jury: many advantages ariſend this way of giving teſtimony, *ore tenus*, a method familiar among the ancient Romans, as may be collected from Quintilian, Inſt. Orat. lib. v. cap. 7. and it was continued as low as the time of Hadrian; but the civil law, as it is now modelled, rejects all public examination of witneſſes. Poſitive proof is always required whenever the nature of the caſe poſſibly admits of it.

Sometimes violent preſumption will be admitted for *evidence* without witneſſes; as where a perſon is run through the body in a houſe, and one is ſeen to come out of the houſe with a bloody ſword, &c. but on this the court ought not to judge haſtily, 1 Inſt. 6. 673; and though preſumptive and CIRCUMSTANTIAL *evidence* may be ſufficient in felony, it is not ſo in treaſon. State Trials.

Though all preſumptive *evidence* of felony ſhould be admitted cautiouſly, for the law holds that it is better that ten guilty perſons eſcape than that one innocent ſuffer.

Evidence by writings and records, is where acts of parliament, ſtatutes, judgments, fines and recoveries, proceedings of courts and deeds, &c. are admitted as *evidence*. The printed Statute Book is good *evidence* upon a general act of parliament, which need not be pleaded; but in the caſe of a private act, it is otherwiſe; for there it muſt be pleaded and examined by the records of parliament before it can be admitted in *evidence*. Records and enrolments prove themſelves; and a copy of a record ſworn to may be given as an *evidence*. A record of an inferior court has been rejected in *evidence*; and the proceedings in county-courts, courts baron, &c. may be denied, and then tried by a jury. A copy of copyhold lands ſhall be an *evidence* where the rolls are loſt. An ancient deed of thirty years ſtanding proves itſelf; but modern deeds, and other writings, muſt be atteſted and verified by parol *evidence* of witneſſes. The counterpart of a deed is no *evidence*, when the original is in being, and can be procured. Although a witneſs ſwear to the hand and contents of a letter, if he never ſaw the party write, it will not be good *evidence*. And a ſhop-book may not be given in *evidence* for goods ſold, &c. by 7 Jac. I. cap. 12. after one year, before the action brought, except there be a bill, &c. for the debt; unleſs between merchant and merchant in the uſual intercourſe of trade. In order to make books *evidence*, if the ſervant who was accuſtomed to make entries in it be dead, his hand muſt be proved; and this, when accompanied with other collateral proofs of fairneſs and regularity, is the beſt *evidence* that can then be produced. In debt, a releaſe may be given in *evidence*; ſo may any matters of fact, tampering with witneſſes or fraud. See Baron Gilbert's Treatiſe of *Evidence*, or the Introduction to the Law of *Niſi Prius*, 4to. 1767.

Sir Thomas Smith reſtrains *evidence* to authentic writings of contracts, written, ſealed, and delivered. De Rep. Ang. lib. ii.

EVIDENCE, *demurrer to*. See DEMURRER.

EVIDENCE, *exception to*. See EXCEPTION.

EVIL, *malum*, in *Ethics*, a privation or abſence of ſome proper or neceſſary good, or of ſome meaſure or degree thereof.

Evil is either *natural* or *moral*, between which there is this relation, that moral *evil* produces natural.

EVIL, *moral*, is defined a deviation from right reaſon; a diſcernment of right from wrong, being given us as a guide of our actions; or it is the diſagreement between the actions of a moral agent and the rule of thoſe actions, whence ſoever it is derived and however made known; and no actions can be morally evil unleſs the agent be properly free, intelligent and free, and capable of diſtinguiſhing, chooſing, and acting for himſelf. This the philoſophers call *ſubmiſſion*, and *hope*, as ſtaining the image of God, and ſullying our original beauty, likewiſe *malum culpæ*.

EVIL, *natural*, is a want of ſomething neceſſary to the *well being*, or perfection of a thing, or to its anſwering all its purpoſes: ſuch are defects in the body, blindneſs, lameneſs, hunger, diſeaſes, death. This ſpecies is denominated *trouble, anguiſhes, torment, and malum pœnæ*.

Again, *evil* is either *objective*, as envy, impiety, &c. or *relative*, as meat, which in itſelf being good, may be *evil* to a man on account of ſome diſeaſe; as wine to a feverith perſon, &c.

A late ingenious author ſets the thing in another light, and furniſhes a theory of moral good and *evil*, in his Enquiry into the Origin of our Ideas of Beauty and Virtue.

Moral evil, according to this philoſopher, denotes our idea of a quality apprehended in actions which excites averſion and diſlike towards the actor, even from perſons who receive no diſadvantage thereby; as moral goodneſs denotes our idea of a contrary quality which procures approbation and love towards the actor, even in perſons unconcerned in its natural tendency. This notion ſuppoſes an univerſally acknowledged difference of good and *evil* from nature. Moral good, we all know, procures love towards thoſe we apprehend poſſeſſed of it; whereas natural good does not. How differently, for inſtance, are we affected towards thoſe we ſuppoſe poſſeſſed of honeſty, faith, generoſity, &c. when we expect no benefit from thoſe qualities, and thoſe poſſeſſed of the natural goods, as houſes, lands, gardens, health, ſtrength, &c. So whatever quality we apprehend morally *evil*, raiſes our hatred towards the perſon in whom we obſerve it; as treachery, cruelty, ingratitude, &c. whereas we love and pity many expoſed to natural *evils*, as pain, hunger, ſickneſs, &c.

The origin of theſe different ideas of actions has greatly puzzled the moraliſts: ſome make ſelf-intereſt, or ſelf-love, the ſource of them all: we approve the virtue of others as it has ſome ſmall tendency to our intereſts, either from its own nature, or from this general conſideration, that a conformity to nature and reaſon is in the general advantageous to the whole, and ſo to us in particular; and on the contrary, diſapprove the vice of others, as tending at the long run to our particular detriment.

Others ſuppoſe an immediate *natural evil* in the actions called *vicious*, that is, that we are determined to perceive ſome deformity or diſpleaſure in ſuch actions, without reflecting on any diſadvantage that may ariſe redound to us from the action; and that we have a ſecret ſenſe of pleaſure accompanying ſuch of our own actions as are called *virtuous*, when we expect no further advantage from them; but then theſe, that we are excited to perform thoſe actions, even as we purſue or purchaſe pictures, ſtatues, landſcapes, &c. from ſelf-intereſt, to obtain the pleaſure which accompanies the action.

But the author juſt mentioned has ſhown the miſtake: ſome actions, he proves, have to men an immediate goodneſs, and others an immediate *evil*; i. e. we perceive pleaſure in ſome and pain in others, and are determined to love or hate the doers, without any view of natural advantage, without any view to future rewards or puniſhments, or even without any intention to obtain the ſenſible pleaſure of the good, but from a very different principle, viz. an internal moral ſenſe, or a natural determination of the mind to receive amiable or diſagreeable ideas of actions, when they ſhall occur to our obſervation, antecedently to any opinion of advantage or loſs to redound to ourſelves from them, even as we are pleaſed with a regular form or an harmonious compoſition, without any knowledge of the mathematics, or feeling any advantage in this form or compoſition different from the immediate pleaſure. But accepting to this account of Dr. Hutcheſon, however plauſible, *moral good* and *evil* ſignify nothing in the objects themſelves, to which they are applied, any more than agreeable and harſh, ſweet and bitter, &c. but only certain effects in

us; and virtue is a mere affair of taſte; whereas it is much more juſt to conclude, that right and wrong, or good and *evil*, are real qualities of actions, and not merely of our minds; and that the power whereby we perceive theſe qualities is not any arbitrary ſenſe but the underſtanding. Price's Original of our Ideas, &c. p. 13. and p. 59, &c. See further under DEFORMITY, SENSE, GOOD, VIRTUE, and VICE.

EVIL, or *King's* EVIL, in *Medicine*, a diſeaſe by the phyſicians, called *ſtrumæ* and *ſcrophulæ*, conſiſting in ſcirrhous tumours, ariſing moſt commonly about the neck; but ſame alſo on the other glandulous parts, as the breaſt, arm-pits, groin, &c.

The kings of England and France have for a long time pretended to the privilege of curing the *king's-evil* by *touching*. The right or faculty, it is ſaid by ſome, was originally inherent in the French kings; and thoſe of England only claimed it as an appendage or appurtenant to that crown, to which they had a claim.

Stephen de Conti, a religious of Corbie, who lived in the year 1400, and wrote a Hiſtory of France, ſtill preſerved in MS. in the library of St. Germains des Prez, deſcribes the practice of *touching* for the *evil*: after the king had heard maſs a veſſel of water was brought him, and his majeſty having put up his prayers before the altar, *touched* the diſeaſed part with his hand, and waſhed it with water.

Matthew Paris will have St. Louis the firſt who practiſed it; others contend, that king Robert was the firſt who was gifted this way. It is certain, we find no mention of any ſuch prerogative before the kings of the eleventh century when that prince reigned. Fa. Daniel, Hiſt. de France, tom i. p. 1032. Polydore Virgil endeavours to prove the ſame virtue in the kings of England. Favyn. Hiſt. de Navarre, 1062.

The author of a late treatiſe tells the following ſtory, which may, perhaps, in ſome degree, account for the miraculous cures ſuppoſed to have been performed by the royal touch. "An old man who was witneſs in a cauſe, had by his evidence fixed the time of a fact by Queen Anne having been at Oxford, and touched him whilſt a child, for the cure of the *evil*. When he had finiſhed his evidence, the relator had an opportunity of aſking him whether he was really cured. Upon which he anſwered with a ſignificant ſmile, that he believed himſelf never to have had a complaint that deſerved to be conſidered as the *evil*; but that his parents were poor, *and had no objection to the bit of gold.*" Obſerv. on the Statutes. 4to. Lond. 170. p. 65. n.

The ſame virtue, we know not on what grounds, is commonly attributed to a ſeventh ſon, born without any daughter between; as alſo to the chiefs of certain particular families, particularly, to the eldeſt perſon of the houſe of Aumont in Burgundy.

The glands are the moſt remarkable ſeat of this diſtemper; and whenever the outward glands appear ſwelled, thoſe of the meſentery may be concluded to be ſo too, the meſentery being uſually the part firſt attacked by this malady.

The particulars to be conſidered in the prognoſtics, are, whether the tumors be many or few; in cluſters, or more diſtinct; great or ſmall, deep or ſuperficial, moveable or immoveable; benign or malignant, ſoft or hard; the ſituation, whether near great veſſels, joints, nerves, tendons, or bones; alſo the habit of the body, and age of the patient.

If the habit of body be tolerable, the patient young, the ſtrumæ recent, and but moderately hard, the reſolution and ſuppuration may be eaſily effected; but if they have been of long continuance, are hard, and lie deep among the veſſels, the cure becomes difficult; yet in both caſes it is promoted by accidental ferments, which often either reſolve or ſuppurate them. If the ſtrumæ be moveable, and free from remarkable veſſels, the extirpation is not difficult; but if the habit of body be bad, and the ſtrumæ immoveable, they are not to be meddled with: if they are moveable, and yet lie deep among the great veſſels, the extirpation is dangerous: beſides, in the beſt habits of body, new ſtrumæ are ready to riſe, while the old ones are extirpating.

Method of cure. In the cure three things are required: 1. A regimen of diet, and other non-naturals. 2. Pharmacy, or internal preſcriptions. 3. The application of externals, either to diſcuſs, ſuppurate, or extirpate the glands.

With reſpect to regimen of diet, regard ought to be had to the conſtitution of the patient, whether it be hot or cold, dry or moiſt, old or young, robuſt or delicate. If the body be cold or moiſt, we generally ſuppoſe a ſurfeit precedèd, and crudity to abound; in which caſe abſtinence from meat and drink, or at leaſt great moderation is requiſite. Their diet ought to be moderately heating and drying, as mutton, kid, rabbit, pullet, chicken, partridge, pheaſant, and other poultry, roaſted, avoiding all aliments which yield groſs phlegmatic nouriſhment, ſuch as water-fowl, fiſh, eſpecially thoſe of ſtanding-waters, herbage, cheeſe, all ſmoaked, ſeaſoned, or dried meats. Their bread ought to be of wheat, well baked, and their drink medicated ale or beer. Wine is allowable, but water prohibited.

In hot and dry conſtitutions, tending to a hectic, diet of a more humid nature may be allowed; meat boiled with lettuce, ſpinnage, purſlain, wood-ſorrel, and the like; to ſome of theſe the eating of any fleſh is ſcarcely to be allowed but rather a milk diet; though where milk is not found agreeable, medicated broths are to be preſcribed. Park is by ſome prohibited to ſtrumous people. Air is a great help to the cure, which ought to be mild and gentle; in cold weather, heating and attenuating; and in the hot, cooling. Exerciſe ought to be enjoined, it being neceſſary to waſte ſuperfluities. Sleep in the day is forbidden, unleſs where the caſe is painful, to which it is an anodyne. The paſſions of the mind ought alſo to be moderated.

The internal preſcriptions muſt be qualified according to the habit of the body. If cold and phlegmatic, abounding with cold viſcous humours, the preſcriptions ought to be heating and attenuating; in plethoric conſtitutions, the ſtronger cathartics ought to be exhibited, or the milder often repeated. The purgatives are, the ſpecies hiera with agaric, diarrhœa, pulvis cornachini, pilulæ cochiæ, e ſubulis, Ruſii, de hermodactylis, aloe-phangimæ, imperiales, e ſuccino, trochiſci, alhandal, diagrydium, reſina jalapii, and mercurius dulcis, with all thoſe medicines preſcribed in the lues venerea.

Alteratives are alſo uſually taken on thoſe days in which the patient does not purge. Among theſe, a decoction of the woods claims a preference; to which are added one or other of the ſpecifics ſo called; ſuch as the roots of ſigwort, dropwort, devil's bit, ſaxifrage, burdock, the bark of the walnut-tree; the herbs ragwort, crane's bill, herb Robert, the greater celandine, hound's tongue, white horehound, fox-glove, and the like. In theſe decoctions it is very common alſo to put a lump of crude antimony of four ounces or half a pound weight, groſly powdered, and tied up in a rag; a ſpecimen of which is in Dr. Fuller's Decoctio Librans. and his Decoctum Edulcorans; of diet, in his Cereiſimæ ad Scrophulas, and his Decoctum ad Scrophulas.

Such as are not able to be at the expence of theſe, or unwilling to be at the trouble of preparing them, which muſt be continued for a long time, may take a ſolution of quick-lime, one pound to a gallon of ſpring water; which being decanted, two or three ounces of the ſhavings of ſaſſafras-wood, with half an ounce or an ounce of liquorice-wood, ſliced, may be ſteeped therein: theſe not only taking off the brackiſh taſte, and changing it for one more pleaſant, but communicating likewiſe a very agreeable colour and ſmell to the ſolution.

The *lapis ſpongius*, or *ſponge-ſtone*, with ſponge itſelf calcined, Dr. Turner ſays, he has often experienced to be ſucceſsful. James Med. Dict. See LANCASTER *ſpring*.

A courſe of bathing in ſalt-water in the warm ſeaſon, and drinking it in ſuch quantities as to keep the body gently open, have in ſome inſtances effected a cure. The patient may be bathed in freſh water where ſalt-water cannot be obtained, and his body kept open by any mild purgative. Next to cold bathing and drinking the ſalt-water, the uſe of the bark has been recommended; the cold bathing to be uſed in ſummer, and the bark in winter. The Moffat and Harrowgate waters, uſed for a conſiderable time, are likewiſe very proper medicines for the ſcrophula. The extract of freſh juice of hemlock may alſo be adminiſtered with advantage. External applications are of little uſe. The beſt dreſſing for the ſores is yellow baſilicon, mixed with about a ſixth or eighth part of its weight of red precipitate of mercury, applied twice a day. Buchan's Dom. Med. p. 436, &c.

EVIL, *falling*, in *Horſes*. See FALLING-*evil*.

EVIL, *hungry*. See HUNGRY and BULIMY.

EULOGY, *Eulogia*, *in Church Hiſtory*. When the Greeks have cut a loaf, or piece of bread, to conſecrate it, they break the reſt into little bits, and diſtribute it among the perſons who have not yet communicated, or ſend it to perſons that are abſent; and theſe pieces of bread are what they call *eulogiæ*.

The Word is Greek, εὐλογία, formed of εὖ, *bene*, *well*, and λογέω, *dico*, *I ſay*, *ſpeak*; q. d. *benedictum*, *bleſſed*: The Latin church has had ſomething like *eulogiæ* for a great many ages; and thence ariſe the uſe of their holy bread.

The name *eulogiæ* was likewiſe given to loaves or cakes brought to church by the faithful to have them bleſſed.

Laſtly, the uſe of the term paſſed hence to mere preſents

made

made a perſon, without any benediction. See the Jeſuit Greiſer, in his Treatiſe de Benedictionibus & Maledictionibus, lib. ii. cap. 22. 24, &c. where he treats of *eulogies* thoroughly.

From a paſſage in Bollandus, on the Life of S. Melaine, cap. 4. it appears, that *eulogiæ* were not only of bread, but any kind of meat bleſſed and hallowed for that purpoſe. Add, that almoſt every body bleſſed and diſtributed *eulogiæ*; not only biſhops and prieſts, but even hermits, though laymen, made a practice of it. Women alſo would ſometimes ſend *eulogiæ*.

The wine ſent as a preſent was alſo held an *eulogy*. Bollandus remarks farther, that the euchariſt itſelf was alſo called *eulogy*.

EULOGY, likewiſe means an encomium on any perſon, on account of ſome virtue or good quality.

EUMARIDES, of εὐμαρὴς, *eaſy*, among the *Ancients*, a kind of ſhoes common to men and women.

The *eumarides* were uſed for pomp and delicacy, being neat, and painted with various colours.

EUMECES, in the *Writings of the ancient Naturaliſts*, the name of a ſtone, which Pliny tells us reſembled a ſtone, and was found in Bactria; the ancients had an idle opinion, that, if laid under the head, it occaſioned true and prophetic dreams, foretelling to the perſon the more remarkable future events of his life. Hiſt. Nat. lib. xxxvii. cap. 10.

EUMENIDES, in *Antiquity*. See FURIES.

EUMENIDEIA, *Eumenidea*, in *Antiquity*, an annual feſtival obſerved in honour of the Furies. It was otherwiſe called *ſemnæ theæ*, becauſe the Athenians called the Furies *ſemnai theai*, i. e. *venerable goddeſſes*.

EUMETRES *Beli*, in *Natural Hiſtory*, the name given by the ancients to a gem which the Aſſyrians held facred to their god, and which many other nations learned from them to ſuppoſe very powerful againſt magic. Many have ſuppoſed this to be the ſtone we now call oculus Beli; but this is an error, ſince Pliny, in his account of the *eumetres*, ſays, that it was of a very fine green. It was probably a gem of the emerald-kind, that ſtone having ever been in very high eſteem in the Eaſtern part of the world, as it is alſo to this day.

EUMOLPIDES, in *Antiquity*, prieſts of Ceres, who had the power among the Athenians of initiating into the myſteries of this goddeſs, or excluding from them.

EUNOFIUS, a name given by ſome authors to the xetites or eagle-ſtone.

EUNOMIANS, a ſect denominated from Eunomius, biſhop of Cyzicus, who, in the fourth century, maintained moſt of the errors of Arius, and added others to them.

He rebaptized ſuch as had already been baptized in the name of the Trinity; he had diſcerned his errors for ſome time; but having at length made a diſcovery, he was expelled his ſee.

The Arians endeavoured to have put him into that of Samoſata, but could not effect it; in lieu thereof the emperor Valens reſtored him to Cyzicus.

EUNOMIÆ'PSYCHIANS, a ſect of hereties of the fourth century, mentioned by Nicephorus, lib. xii. cap. 30. being the ſame with thoſe called *Eutychians* by Sozomen, lib. vii. cap. 17. See EUTYCHIANS.

EUNUCH, *Eunuchus*, a term applied in the general to all who have not the faculty of generating, either through imbecility or frigidity; but more particularly to ſuch as have been caſtrated, or have loſt ſome of the parts neceſſary for that purpoſe.

The word is formed of εὐνὴν ἔχειν, q. d. *lecti curam habet, guardian, or keeper of the bed.*

In England, France, &c. *eunuchs* are never made but on occaſion of ſome diſeaſe which renders ſuch an operation neceſſary; but in Italy they make *eunuchs* for the ſake of preſerving the voice; and in the Eaſt they make *eunuchs* to be guards or attendants on their women.

Great numbers of children, from one to three years of age, are yearly caſtrated in Italy to ſupply the operas and theatres, not only of Italy but other parts of Europe, with ſingers; though it is not one in three, that after having loſt their virility, have a good voice for a recompence. See CONSERVATORIO.

Tavernier aſſures us, that in the kingdom of Boutan in the Eaſt Indies, there are every year made twenty thouſand *eunuchs*, and ſold thence into other countries.

The ſeraglios of the Eaſtern emperors are chiefly ſerved and guarded by *eunuchs*; and yet we have very good teſtimonies, that the rich *eunuchs* in Perſia and other countries keep ſeraglios for their own uſe. This is a puniſhment of crimes in ſome countries. See ADULTERY.

By an arret of the grand chamber of Paris in 1665, it is adjudged that an *eunuch* could not marry, not even with the conſent of the woman, and all the parties on both ſides.

Claudian has a very ſevere ſatire againſt the *eunuch* Eutropius, who had been elected conſul of Rome. He repreſents him as an old woman, dreſſed up in the honours of the conſulate.

In the council of Nice thoſe were condemned, who, out of an indiſcreet zeal, and to guard themſelves from ſenſual pleaſures, ſhould make themſelves *eunuchs*. Such as thus mutilated their bodies were excluded from holy orders; witneſs Leontius, biſhop of Antioch, who was depoſed for having practiſed this cruelty on himſelf: and the biſhop of Alexandria excommunicated two monks who had followed his example, on pretence of ſecuring themſelves from the impetuous motions of concupiſcence.

Several of the emperors made very ſevere prohibitions againſt the making of *eunuchs*, or people's caſtrating themſelves. See CASTRATION.

EUNUCHS, EUNUCHI, is alſo the denomination of a ſect of hereties in the third century, who had the folly or madneſs to caſtrate not only thoſe of their own perſuaſion, but even all they could lay hands on.

They took their riſe from the example of Origen, who, upon a miſunderſtanding of our Saviour's words in St. Matthew, chap. xix. ver. 12. made himſelf an *eunuch*, by cutting off the offending part, as ſome ſay; or, as others (particularly St. Epiphanius), by the uſe of certain medicines. Theſe hereties were alſo called VALESIANS.

EVOCATI, among the Romans, ſoldiers, who having ſerved their time in the army, went afterwards volunteers at the requeſt of ſome favourite general.

EVOCATION, *Evocatio*, among the Romans, a religious ceremony always obſerved by them at undertaking the ſiege of a town, wherein they ſolemnly called upon the gods and goddeſſes of the place to forſake it and come over to them. Without the performance of this ceremony, they either thought that the place could not be taken, or that it would be a ſacrilege to take the gods priſoners.

The form of *evocation* uſed at taking the city of Carthage is related by Macrob. Sat. III. 9.

They always took it for granted that their prayer was heard, and that the gods had deſerted the place and came over to them, provided they were able to make themſelves maſters of it.

EVOCATORIÆ *epiſtolæ*, among the Romans, letters ſent by the emperors to command the attendance of any perſon; or letters granting licence to any one to wait on the emperor; every perſon not being allowed this privilege till they had deſired and obtained the *evocatoriæ epiſtolæ*.

EVOLVENT, in *Geometry*, a term which ſome writers uſe for the curve reſulting from the evolution of a curve; in contradiſtinction to the *evolute*, which is the curve ſuppoſed to be opened or evolved.

The evolute always both touches and cuts the *evolvent* at the ſame time: the reaſon is, that it has two of its infinitely ſmall ſides in common with the *evolvent*; or, rather exactly placed on two equal ſides thereof; one of them within-ſide that of the *evolvent*, i. e. on the concave ſide thereof; and the other on the convex ſide of its correſpondent ſide; ſo that the evolute touches the *evolvent* in two points; whence, inſtead of being a tangent, it is ſaid to oſculate the *evolvent*; and, hence, it is alſo called *oſculator*, and *circulus oſculator*.

There is one, and but one oſculator, to each point of the *evolvent*; but, to the ſame point, there are an infinity of other circles which only touch, and do not oſculate. The oſculator, and the evolute, make no angle in the place where they touch and cut; nor can any curve line be drawn between, as there may between a tangent and a curve.

EVOLUTE, EVOLUTA, in the *Higher Geometry*, a curve firſt propoſed by Mr. Huygens, and ſince much ſtudied by the later mathematicians.

The *evolute* is a curve, ſuppoſed to be evolved, or opened; and which, in opening, deſcribes other curves.

To conceive its origin and formation, ſuppoſe a flexible thread, wound exactly over the convexity of any curve, as ABCG (*Tab.* II. *Geometry*, *fig.* 34.) and ſuppoſe the thread fixed in G, and every where elſe at liberty, to A. Now, beginning to unwind the thread from the point, and continuing it to D, and, throughout, keeping it tight on the curve ſurface ABCG, when the thread is become quite ſtraight, and is only a tangent, FG, to the curve in the point G, it is evident the extremity A, in its progreſs to F, has deſcribed another curve line ADEF.

Here, the firſt curve ABCG, is called the *evolute*; each of its tangents BD, CE, &c. comprehended between it and the curve ADEF, called the *involute*, is called a *radius of the evolute*, or *radius oſculi*, *radius oſculator*, or *radius* of curvature, of the curve ADEF, in the reſpective points D, E, &c. And the circles, whereof the oſculators BD, CE, &c. are radii, are called *circuli oſculi-*

tures of the curve ADEF, in D, E, &c. And, lastly, the new curve resulting from the evolution of the first curve begun in A, is called the *curve of evolution*, or *curve described by evolution*.

EVOLUTE, *the radius of the*, then, is the part of the thread comprised between any point where it is a tangent to the *evolute*, and the correspondent point where it terminates in the new curve. Which appellation, *radius*, is the more proper, as one may actually consider this part of the thread, in every ſtep it takes, as if it deſcribed an arc of an infinitely ſmall circle, making a part of the new curve, which thus conſiſts of an infinite number of ſuch arcs, all deſcribed from different centres, and with different radii.

Every curve, therefore, may be conceived as formed by the evolution of another. And we are to find that, whoſe evolution formed it; which amounts to the finding of the radius of the *evolute* in any point; for, as it is always a tangent to the generating curve, it is, properly, no more than one of its infinitely ſmall parts, or ſides, prolonged; and all its ſides, whoſe poſitions are determined of courſe, are no other than the generating curve itſelf.

The ſame thread is alſo called *radius osculatrix*, or *radius oſculi*, becauſe a circle deſcribed therby, from the centre G, is ſaid to oſculate, or kiſs it, as both touching and cutting at the ſame time, i. e. touching both the inſide and the out.

Hence, 1. The *evolute* BCF (*fig.* 35.) is the place of all the centres of the circles that oſculate the curve AM, deſcribed by evolution. 2. When the point B falls on A, the radius of curvature, or rad us of the *evolute*, MC, is equal to the arch BC; or to the aggregate of AB, and the arch BC. 3. Since the element of the arch M*m*, in the curve deſcribed by evolution, is an arch of a circle deſcribed by the radius CM; the radius of the *evolute* CM is perpendicular to the curve AM, or to a tangent at the point M. 4. Since the radius of the *evolute*, MC, is always a tangent to the *evolute* BCF, curves by evolution may be deſcribed through innumerable points, if only tangents be produced in the ſeveral points of the *evolute*, till they become equal to their correſpondent arcs.

The finding of the *radii of evolutes*, is a thing of great importance in the higher ſpeculations of geometry; and even, ſometimes, is of uſe in practice; as the inventor of the whole theory, Huygens, has ſhewn, in applying it to the pendulum. Horol. Oſcill. part 3. The doctrine of the *ſcheſis of evolutes* is owing to M. Leibnitz, who firſt ſhewed the uſe of *evolutes* in the meaſuring of curves.

We ſhall here ſubjoin a brief account of the method of finding the radius of the *evolute* in different kinds of curves and equations expreſſing the nature of *evolutes*.

1. To form a general expreſſion for (BE) the radius of the *evolute*, or of curvature at any point B in the involute curve ABY, whoſe axis is AX, and *evolute* DE. *Tab.* II. *Geometry, fig.* 36.

With the radius EB deſcribe the circular arc BK, which will have the ſame CURVATURE with the involute curve AB at the point B. Draw the radius EK parallel to the axis AX, and produce the ordinate BC to L, to which draw AN parallel: let the abſciſs AC be $= x$, the ordinate CB $= y$, radius EB or EK $= r$, KN $= a$, and NA $= b$; then LE $= r - a - x$. If the abſciſs x be ſuppoſed to increaſe uniformly, and B*m* to be a tangent at the point B; and *m n* be drawn parallel to BC, and B*n* parallel to AX; B*n*, *n m*, and *m* B, which are the contemporary increments of the abſciſſa, ordinate, and curve, will be as their FLUXIONS reſpectively; or B*n* will be as $\dot{x}$, *n m* as $\dot{y}$, and B*m* $(= \mathrm{B}n^2 + nm^2)^{\frac{1}{2}}$ as $\overline{\dot{x}^2 + \dot{y}^2}^{\frac{1}{2}}$. Farther, the triangles B*n m* and BLE are ſimilar; therefore, B*n* : *n m* :: BL : LE, i. e. $\dot{x} : \dot{y} :: b + r - a - x : y$; conſequently, $r\dot{x} - a\dot{x} - x\dot{x} = y\dot{y} + b\dot{y}$: the fluxion of which equation (ſuppoſing $\dot{x}$ invariable, and therefore, the direction of the curve AB continually approaching towards a parallelism with its axis, the fluxion of y is negative) is $-\dot{x}^2 = \dot{y}^2 - y\ddot{y} - b\ddot{y}$; and $\dot{x}^2 + \dot{y}^2 = b\ddot{y} + r\dot{x}$. Again, LB : BE :: B : B*m*, i. e. $b + y : r :: \dot{x} : \overline{\dot{x}^2 + \dot{y}^2}^{\frac{1}{2}}$; therefore $b + y = \frac{r\dot{x}}{\overline{\dot{x}^2 + \dot{y}^2}^{\frac{1}{2}}}$, and ſubſtituting this expreſſion for $b + y$, the above equation will become $\dot{x}^2 + \dot{y}^2 = \frac{r\dot{x}\ddot{y}}{\overline{\dot{x}^2 + \dot{y}^2}^{\frac{1}{2}}}$; conſequently, $\overline{\dot{x}^2 + \dot{y}^2} \times \overline{\dot{x}^2 + \dot{y}^2}^{\frac{1}{2}} = r\dot{x}\ddot{y}$, i. e. $\overline{\dot{x}^2 + \dot{y}^2}^{\frac{3}{2}} = r\dot{x}\ddot{y}$, and $\frac{\overline{\dot{x}^2 + \dot{y}^2}^{\frac{3}{2}}}{\dot{x}\ddot{y}} = r = \mathrm{BE}$. In deducing this expreſſion, the increment of the ordinate y, or the velocity or fluxion with which it flows, is ſuppoſed continually to decreaſe, therefore its ſecond fluxion is negative; but when y increaſes with an accelerated motion, its ſecond fluxion will be affirmative; and the above expreſſion will be $\frac{\overline{\dot{x}^2 + \dot{y}^2}^{\frac{3}{2}}}{-\dot{x}\ddot{y}}$. By ſubſtituting 1 for $\dot{x}$, which is invariable in theſe expreſſions, they will become $\frac{\overline{1 + \dot{y}^2}^{\frac{3}{2}}}{\ddot{y}}$ and $\frac{\overline{1 + \dot{y}^2}^{\frac{3}{2}}}{-\ddot{y}}$ reſpectively; the former taking place when the curve is concave, and the latter when it is convex towards the axis, and the ſign of $\ddot{y}$ ſhewing the poſition of the *evolute* and radius of curvature with reſpect to the curve and axis. By reducing theſe expreſſions from the nature and properties of the curve, and always ſubſtituting 1 for $\dot{x}$, we ſhall obtain the value of BE, or the radius required. The vertical diſtance or radius AD may be eaſily obtained by ſubſtituting for $\dot{x}$, 1, and for $\dot{y}$ its proper value in the expreſſion for the ſubcontrai CH, which is evidently $\frac{\dot{y}\dot{x}}{\ddot{y}}$. E. gr. 1. To find the radius of curvature at any point B in the PARABOLA AY, *fig.* 37. Let the parameter be $= a$, abſciſs AC $= x$, and ordinate CB $= y$: then, by the nature of the curve $ax = y^2$, and therefore $a\dot{x} = 2y\dot{y}$ (ſee FLUXION), and making $\dot{x} = 1$, $a = 2y\dot{y}$, and $\dot{y} = \frac{a}{2y} = \frac{a}{2 \times ax}^{\frac{1}{2}}$. But the fluxion of this equation will be $-\dot{y} = \frac{-a^2}{4 \times ax}^{\frac{1}{2}}$, or $\dot{y} = \frac{a^2}{4 \times ax}^{\frac{1}{2}}$, and $\dot{y}^2$ being equal to $\frac{a^2}{4ax} = \frac{a}{4x}$, we ſhall have, by ſubſtituting theſe values in the expreſſion $\frac{\overline{1 + \dot{y}^2}^{\frac{3}{2}}}{\ddot{y}}$ for $\dot{y}^2$ and $\ddot{y}$,

$$\frac{\overline{1 + \frac{a}{4x}}^{\frac{3}{2}}}{\frac{a^2}{4x} \times 4 \cdot ax}^{\frac{1}{2}} = \frac{4}{a^2} \times \frac{\overline{4x + a}^{\frac{3}{2}}}{4^{\frac{3}{2}}} \times \overline{ax}^{\frac{1}{2}} = \frac{4}{a^2} \times \frac{\overline{4ax + a^2}^{\frac{3}{2}}}{4x}^{\frac{1}{2}} = \frac{4}{a^2} \times \frac{1}{a^{\frac{1}{2}}} \times 4ax + a^{\frac{1}{2}} = \frac{4}{a^2} \times \frac{1}{8} \times \overline{4ax + a^2}^{\frac{3}{2}} = \frac{\overline{4ax + a^2}^{\frac{3}{2}}}{2a^2}.$$

Then if a ſemicircle be deſcribed through the point B, C*n* be biſected in H, and H*r* be made equal to AC, and *r* E be a perpendicular to it, produced till it meets a line BE, drawn from B through H, this line BE will be the radius of curvature required: for BC^2 $=$ AC $\times$ C*n*, 35 E. 3. or $\overline{\mathrm{AC}}^{\frac{1}{2}} = \mathrm{C}n$, i. e. $\frac{ax}{y} = a = \mathrm{C}n$, and CH $= \frac{1}{2}a$, and C*r* $= \frac{1}{2}a + 2x$; and by 47 E. 1. $\overline{\mathrm{CH}^2 + \mathrm{CB}^2}^{\frac{1}{2}} = \mathrm{BH}$, i. e. $\overline{\frac{1}{4}a^2 + ax}^{\frac{1}{2}} = \mathrm{BH}$; and by 4 E. 6. CH : HB :: C*r* : BE; i. e. $\frac{1}{2}a : \overline{\frac{1}{4}a^2 + ax}^{\frac{1}{2}} :: \frac{1}{2}a + 2x : \frac{a + 4x}{a} \times \overline{\frac{1}{4}a^2 + ax}^{\frac{1}{2}} = \frac{\overline{a^2 + 4ax}^{\frac{3}{2}}}{2a^2} = \mathrm{BE}$ as before. AD the vertical diſtance, or $\frac{y\dot{x}}{\dot{y}}$, is in this caſe, putting $\frac{a}{2y}$ for $\dot{y}$, and 1 for $\dot{x}$, equal to $\frac{a}{2y}$; and this likewiſe appears, by conſidering, that in the expreſſion for the radius, when the radius becomes equal to the vertical diſtance, the abſciſs x vaniſhes, and it becomes $\frac{\overline{ax}^{\frac{3}{2}}}{2a^2} = \frac{a^{\frac{3}{2}}x^{\frac{3}{2}}}{2a^2} = \frac{x^{\frac{3}{2}}}{2a^{\frac{1}{2}}} = \frac{a}{2}$.

E. gr. 2. To find the radius of curvature at any point B in the cycloid ABD, *fig.* 38.

Put the radius OF or OD $= a$, abſciſs AC $= x$, ordinate CB $= y$, ſine IG $= z$, and arc FG $= u$. Now, by 33 E. 3. IG $= \overline{\mathrm{DI} \times \mathrm{IF}}^{\frac{1}{2}}$, that is, $z = \overline{2ay - y^2}^{\frac{1}{2}}$; the fluxion of which equation is $\dot{z} = \frac{a\dot{y} - y\dot{y}}{\overline{2ay - y^2}^{\frac{1}{2}}}$; and by the nature of the cycloid, arc DG $=$ GB; and therefore, arc FG $=$ GI $+$ AC, or AC $=$ arc FG $-$ GI, that is, $x = u - z$ (by ſubſtituting for z its above value), $\dot{x} = \dot{u} - \frac{a\dot{y} - y\dot{y}}{\overline{2ay - y^2}^{\frac{1}{2}}}$; and the fluxion of this equation, making $\dot{x} = 1$, is $1 = \dot{u} - \frac{a\dot{y} - y\dot{y}}{\overline{2ay - y^2}^{\frac{1}{2}}}$.

But $\dot{u} = \overline{1 + \dot{y}^2}^{\frac{1}{2}}$ = (by writing for $\dot{u}$ its above value), $\overline{\frac{a\dot{y} - y\dot{y}}{\overline{2ay - y^2}^{\frac{1}{2}}} + \dot{y}^2}^{\frac{1}{2}} = \frac{a\dot{y}}{\overline{2ay - y^2}^{\frac{1}{2}}}$; which, ſubſtituted

for

for x, makes the above equation $1 = \frac{a\dot{y}}{2ay-y^2}^{\frac{1}{2}} + \frac{y\dot{y}-a\dot{y}}{2ay-y^2}^{\frac{1}{2}}$; that is, $1 = \frac{y\dot{y}}{2ay-y^2}^{\frac{1}{2}}$; therefore, $\dot{y} = \frac{2ay-y^2}{y}^{\frac{1}{2}}$; and the fluxion of this equation (the fluxion of y being negative), is $-\dot{y} = \frac{a\dot{y}y - y^2\dot{y}}{2ay-y^2}^{\frac{1}{2}} - \dot{y}.2ay-y^2^{\frac{1}{2}} = \frac{-a\dot{y}}{y.2ay-y^2^{\frac{1}{2}}} =$ (by writing for $\dot{y}$ its equal), $-\frac{a}{y^2}$; that is, $\dot{y} = \frac{a}{y^2}$.

Now, by substituting $\frac{2ay-y^2}{y^2}$ for $\dot{y}$, and $\frac{a}{y^2}$ for $\dot{y}$, we have $\frac{1+\dot{y}^2}{\dot{y}}^{\frac{1}{2}} = \frac{1+\frac{2ay-y^2}{y^2}}{a}^{\frac{1}{2}} \times y^2 = \frac{2ay}{ay}^{\frac{1}{2}} = \frac{2ay \times 2ay}{ay}^{\frac{1}{2}} = 2.\overline{2ay}^{\frac{1}{2}} =$ BE, the radius of curvature required.

Confirmation. Make FH = CB; and through the point H draw the right line BE, making BH = HE = chord FG; then will BE be the radius of curvature at the point B; for a tangent to the point B is parallel to the chord DG, and the radius of curvature is always perpendicular to the tangent; therefore, because by 31 E. 3. the ∠ DGF is right, BE must be parallel to the chord FC. Now, by 4 and 8 E. 6. DF : FG :: GF : FI, or CB, ∵ GF = DF × CB.$^{\frac{1}{2}}$ = $2ay^{\frac{1}{2}}$, and 2 GF = 2 . $2ay^{\frac{1}{2}}$ = BE.

2. To form a general expreſſion for the radius of curvature in SERIALS, or curves whoſe ordinates are referred to a fixed or central point:

Let CBY, *fig.* 30. be the curve, C the central point, or that from which all the ordinates iſſue; and BE the radius of curvature at the point B, that is, let the point E be ſuppoſed in the *evolute* curve: conceive C*b* and E*b* indefinitely near to CB and EB, that is, let the points B and *b* be ſuppoſed indefinitely near to each other; and let CF and C*f* be perpendicular to EB and E*b* reſpectively, then will the points F and *r* be indefinitely near to a coincidence; and therefore B*r* and C*r* may be taken as equal to BF and CF. Now, if with the ordinate CB as a radius, the little circular arc B*n* be deſcribed and conſidered as a little right line perpendicular to C*b*, and the increment B*b* be conſidered as coinciding with a tangent to the point B, then the little right-angled triangle B*nb* will be ſimilar to the right-angled triangle BFC; (for ∠ CB*n* = ∠ EB*b*, and therefore, ∠ EB*n* being common, the ∠ CBF = ∠ *n*B*b*; and conſequently, the angles at F and *n* being right, ∠ BCF = ∠ B*bn*); therefore, by 4 E. 6. *b*B : B*n* :: CB : BF; that is, (if we put the ordinate CB = y, B*n* = x, and *nb* = $\dot{y}$, when by 47 E. 1. B*b* will be = $\dot{x}^2+\dot{y}^2^{\frac{1}{2}}$,) $\dot{x}^2+\dot{y}^2^{\frac{1}{2}} : \dot{x} :: y : \frac{\dot{x}y}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}}$ = BF or B*r*; and B*b* : *bn* :: BC : CF, that is, $\dot{x}^2+\dot{y}^2^{\frac{1}{2}} : \dot{y} :: y : \frac{y\dot{y}}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}}$ = CF or C*r*; the increment of which is $r\dot{f}$; that is, (ſuppoſing $\dot{x}$ to be invariable) $\frac{\dot{y}\dot{x}^2+\dot{y}\dot{y}^2 \times \dot{x}\dot{x}^2+\dot{y}^2^{\frac{1}{2}} - \frac{\dot{x}\dot{y}\dot{x} \times y\dot{y}}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}}}{\dot{x}^2+\dot{y}^2} = \frac{\dot{x}^2\dot{y}^2+\dot{y}^4+y\dot{x}^2\dot{y}'}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}} = r\dot{f}$. Again, the triangles E*bb* and E*rf* being ſimilar, B*b* − *r*$\dot{f}$: B*b* :: (BE − *r*E, or) *r*B : BE; that is, $\frac{(\dot{x}^2+\dot{y}^2)^{\frac{3}{2}} - \dot{x}^2\dot{y}'+\dot{y}^4+y\dot{x}^2\dot{y}'}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}} : \frac{\dot{x}^2+\dot{y}^2 \times \dot{x}^2+\dot{y}^2 - y\dot{x}^2\dot{y}'}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}} :: \frac{\dot{x}^2\dot{y}}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}} : \frac{y\dot{x}^2+\dot{y}^2}{\dot{x}^2+\dot{y}^2^{\frac{1}{2}}}$ = BE, or BE = $\frac{y\dot{x}^2+\dot{y}^2}{\dot{x}^2+\dot{y}^2-y\dot{y}'}$; which is a general expreſſion for the radius of curvature of all curves referred to a fixed or central point, when $\dot{x}$ or $\dot{x}$ is invariable.

Hence, if $\dot{x}$ be made = 1, the general expreſſion for the radius of curvature will be = $\frac{y \times 1+\dot{y}^2^{\frac{1}{2}}}{1+\dot{y}^2-y\dot{y}'}$. Wherefore, if we put the equation of the given ſpiral into fluxions, making $\dot{x}$ = 1, and put this fluxional equation into fluxions again; and from thence, or from the nature of the curve, find the values of $\dot{y}^2$ and $\dot{y}'$ then, if for $\dot{y}^2$ and $\dot{y}$ we ſubſtituote theſe their values, in this general expreſſion, we ſhall have BE the radius of curvature required.

E. g. To find the radius of curvature at any point B in the ſpiral of Archimedes, CB, &c. *fig.* 40. Put the circumference of the generating circle AF, &c. = b, and its radius CA = $\frac{b}{2}$ = a; ordinate CB = y, arc AF = z. Let C*f* be ſuppoſed indefinitely near to CB, that is, let the ∠ FC*f* be ſuppoſed indefinitely ſmall; and with the ordinate CB as a radius deſcribe the little circular arc B*n*, which put = $\dot{x}$; alſo put F*f* = $\dot{z}$. Now, by the nature of the curve, $a : b :: z : y$, or $z = \frac{by}{a}$, the fluxion of which equation is $\dot{z} = \frac{b\dot{y}}{a}$; and by the ſimilar ſectors CB*n* and CF*f*, $y : \dot{x} :: b : \dot{z} = \frac{b\dot{x}}{y}$, or, $\dot{z} = \frac{b\dot{x}}{y}$. Hence, $\frac{b\dot{y}}{a} = \frac{b\dot{x}}{y}$; that is, (making $\dot{x}$ = 1,) $\frac{b\dot{y}}{a} = \frac{b}{y}$; from which equation we have $\dot{y} = \frac{b^2}{ay}$; therefore, $\dot{y}^2 = \frac{b^4}{a^2y^2}$, and $\dot{y}' = \frac{-ab^4\dot{y}}{a^2y^3} =$ (by writing for $\dot{y}$ its value), $\frac{-b^6}{a^3y^3}$; and if we ſubſtitute for $\dot{y}^2$ and $\dot{y}$ theſe their values, we ſhall have $\frac{y \times 1+\dot{y}^2^{\frac{1}{2}}}{1+\dot{y}^2-y\dot{y}'} = \frac{y \times 1+\frac{b^4}{a^2y^2}^{\frac{3}{2}}}{1+\frac{b^4}{a^2y^2}+\frac{ab^6}{a^3y^3}} = \frac{a^3y^3+b^6}{a^3y^3+2ab^6}^{\frac{3}{2}} =$ BE, the radius of curvature ſought.

Conſtruction. Through the centre C draw the indefinite right line H*v* perpendicular to the ordinate CB; draw the tangent TB, perpendicular to which draw BH, produce BC to V, making BR = TH, and RV = CH; with DV and BR as radii, deſcribe the arcs V*v* and R*r*; draw the right line *v*B; and from the interſecting point *r* draw *r*E parallel to *v*H; then will BE be the radius of curvature at the point B: for, CT = $\frac{y\dot{z}}{\dot{b}}$, that is, by ſubſtituting $\frac{a\dot{y}}{b}$ for $\dot{z}$, CT = $\frac{ay\dot{y}}{b^2}$; and by 8 and 4 E. 6. TC : CB :: CB : CH, that is, $\frac{ay\dot{y}}{b^2} : y :: y : \frac{b^2}{a}$ = CH; therefore, TH = BR = B*r* = $\frac{ay\dot{y}}{b^2} + \frac{b^2}{a}$, and BV = B*v* = $\frac{ay\dot{y}}{b^2} + \frac{2b^2}{a}$; and by 47 E. 1. HB = BC^2 + CH^2.$^{\frac{1}{2}}$ = $y^2 + \frac{b^4}{a^2}^{\frac{1}{2}} = \frac{a^2y^2+b^4}{a^2}^{\frac{1}{2}}$; again, by 4 E. 6. B*v* : BH :: B*r* : BE, that is, $\frac{ay\dot{y}}{b^2} + \frac{2b^2}{a} : \frac{a^2y^2+b^4}{a}^{\frac{1}{2}} :: \frac{ay\dot{y}}{b^2} + \frac{b^2}{a} : \frac{a^2y^2+b^4}{a}^{\frac{1}{2}} \times \frac{a^3y^3+b^6}{a^2y^2+2b^4} = \frac{a^3y^3+b^6}{a^3y^3+2ab^6}^{\frac{3}{2}} =$ BE.

3. To find an equation that ſhall expreſs the nature of the *evolute* of a given involute curve.

Let BE be the radius of evolution or curvature at any point B in the involute curve AB, *fig.* 41. whoſe abſciſs is AC = x, and ordinate CB = y. Parallel to HA draw EN; produce BC to I.; and equal and parallel to CI., draw DN from the vertex of the *evolute* DE: then will the triangles BHC and BEL be ſimilar: and therefore, by 4 E. 6. BH : HC :: BE : EL, that is, $\frac{\dot{y}}{\dot{x}} \times \overline{\dot{x}^2+\dot{y}^2}^{\frac{1}{2}} : \frac{\dot{y}\dot{y}}{\dot{x}} :: \frac{\dot{x}^2+\dot{y}^2}{\dot{x}\dot{y}} : \dot{y} \times \frac{\dot{x}^2+\dot{y}^2}{\dot{x}\dot{y}} =$ EL; and HC : CB :: EL : LB, that is, $\frac{\dot{x}\dot{y}}{\dot{x}} : y :: y \times \frac{\dot{x}^2+\dot{y}^2}{\dot{x}\dot{y}} : \frac{\dot{x}^2+\dot{y}^2}{\dot{y}} =$ LB. Now, theſe are general expreſſions for EL and LB, when $\dot{x}$ is conſidered as invariable, and the fluxion of $\dot{y}$ as negative. Hence, therefore,

If $\dot{x}$ = 1, and the fluxion of $\dot{y}$ be negative, the general expreſſion for BL will be = $\frac{1+\dot{y}^2}{\dot{y}}$, and this multiplied

plied by y is $y \times \frac{z+y}{y} =$ the general expreſſion for LE. Now, by help of the equation of the given involute curve, exterminate z, y, and s, out of theſe expreſſions, and find the vertical diſtance AD. Then, if we put the abſciſs of the *evolute* DN $= x$, and its ordinate NE $= v$; by help of theſe two equations, $x =$ BL $-$ BC, and $v =$ AC $-$ AD $+$ LE, we may get the nature of the *evolute* curve DE required.

Note. If the given involute be convex towards its axis, and x and y increaſe together, or the fluxions of x and y be both affirmative, then the general expreſſions for BL and LE will be $\frac{z+y}{-y}$; and $y \times \frac{z+y}{-y}$ reſpectively; wherein the negative ſign ſhews, that the points L and E muſt be taken on the concave ſide of the involute curve, that is, on the other ſide of it with regard to x and y.

E. gr. To find the nature of the curve AEP, *fig.* 42. by whoſe evolution the cycloid ABD is deſcribed.

Put AC $= z$, CB $= y$, arc FG $= z$, and OD or OF $= a$; then by Ex. 2. art. 1. above, $z = \frac{2ay-y^2}{y}$, $z^2 = \frac{2ay-y^2}{y^2}$, and $\dot{z} = \frac{a}{y^2}\dot{y}$; wherefore, BL $= \frac{1+\frac{2ay-y^2}{y^2} \times y^2}{a} = 2y$, and LE $= \dot{z} \times$ BL $= \frac{2ay-y^2}{y}^{\frac{1}{2}} \times 2y = 2.\overline{2ay-y^2}^{\frac{1}{2}}$. Hence, if we put the abſciſs AN $= u$, and ordinate NE $= v$, we have x (BL $-$ CB $=) 2y - z =$ *y*, and $v =$ (AC $+$ LE $=) z + 2.\overline{2ay-y^2}^{\frac{1}{2}}$, that is, (becauſe $x = z - \overline{2ay-y^2}^{\frac{1}{2}}$,) $v = z + 2\overline{2ay-y^2}^{\frac{1}{2}}$, or, (writing u for y its equal,) $v = z + 2\overline{2au-u^2}^{\frac{1}{2}}$. Wherefore, the *evolute* curve AEP is a cycloid, and equal to the given cycloid ABD; for, let AS $=$ SV $= a$, then (AN being $=$ FI,) AT $=$ FG $= z$, and NT $= \overline{2au-u^2}^{\frac{1}{2}} =$ IG; and therefore, AT $+$ TN $= z + \overline{2au-u^2}^{\frac{1}{2}}$, that is, AT $+$ TN $=$ NE, which is the property of the cycloid; therefore, the *evolute* AEP is a cycloid; and becauſe AV $=$ FD, therefore the cycloids AEP and ABD are equal. See CYCLOID.

The *evolute* of a ſpiral, or indeed of any other curve, may be deſcribed by finding the radii of curvature at ſeveral points in the involute; for then we ſhall have as many points in the *evolute*, through which if a curve line be drawn, it will be the *evolute* ſought.

Wolf. Elem. Math. tom. i. p. 522, ſeq. or the Infinitæ Petites of M. le Marquis de l'Hôpital. Simſon's Fluxions, vol. i. p. 71. &c. And Rowe's Fluxions, edit. 3. 1767, chap. vi. and vii. p. 103—132.

Since the radius of an *evolute* is either equal to an arc of the *evolute*, or exceeds it by ſome given quantity, all the arcs of *evolutes* may be rectified geometrically, whoſe radii may be exhibited by geometrical conſtructions; whence we ſee why an arc of a cycloid is double its chord; the radius of the *evolute* being double the ſame, and the *evolute* of a cycloid being itſelf a cycloid, equal and ſimilar to the involute.

M. Varignon has applied the doctrine of the radius of the *evolute* to that of central forces; ſo that having the radius of the *evolute* of any curve, one may find the value of the central force of a body; which, moving in that curve, is found in the ſame point where that radius terminates; or reciprocally, having the central force given, the radius of the *evolute* may be determined. Hiſt. de l'Acad. Roy. des Sciences, an. 1706.

The variation of curvature of the line deſcribed by the *evolution* of a curve, is meaſured by the ratio of the radius of curvature of the *evolute*, to the radius of curvature of the line deſcribed by the *evolution*. See Maclaurin's Flux. art. 402. prop. 36.

EVOLUTE, *imperfect*. M. Reaumur has given a new kind of *evolute*, under this denomination. Hitherto the mathematicians had only conſidered the perpendiculars let fall on the points of the convex ſide of the curve: if other lines not perpendicular were drawn upon the ſame points, provided they were all drawn under the ſame angle, the effect would be the ſame; that is, the oblique lines would all interſect within the curve; and, by their interſections, form the infinitely ſmall ſide of a new curve; whereof they would be ſo many tangents.

This curve would be a ſort of *evolute*, and would have its radii; but an imperfect *evolute*, ſince the radii are not perpendicular to the firſt curve. Hiſt. de l'Acad. &c. an. 1709.

EVOLUTION, *in Geometry*, the unfolding, or opening, of a curve, and making it deſcribe an EVOLVENT.

The word *evolution* is formed of the prepoſition *e*, *out*; and *volvo*, I *roll*, or *wind*; q. d. an *unwinding*, or *unrolling*.

The equable *evolution* of the periphery of a circle, or other curve, is ſuch a gradual approach of the circumference to rectitude, as that its parts do all concur, and equally evolve, or unbend; ſo that the ſame line becomes ſucceſſively a leſs arc, of a reciprocally greater circle; till, at laſt, they change into a ſtraight line. In the Philoſophical Tranſactions, N° 260. a new quadratrix to the circle is found by this means, being the curve deſcribed by the equable *evolution* of its periphery.

EVOLUTION, is alſo uſed for the EXTRACTION of roots out of powers.

In which ſenſe it ſtands oppoſed to *involution*.

EVOLUTION, in the *Art of War*, is a term applied to the diverſe figures, turns and motions, made by a body of ſoldiers, either in ranging themſelves in form of battle, or in changing their form; and this, whether in the way of exerciſe, or in the time of an actual engagement.

It is by the *evolutions* that the form and poſture of a battalion, ſquadron, &c. are changed, either to make good the ground they are upon, or to poſſeſs themſelves of another, that they may attack the enemy or receive an onſet more advantageouſly

The *military evolutions* are converſions, countermarches, or wheelings, doublings of rank or file, &c. See EXERCISE.

Fa. Hoſte, a Jeſuit, in 1697, printed a Treatiſe on *Naval Evolutions*, in folio. By *naval evolutions* he means the motions made by a fleet, ſquadron, or naval armament, in order to put themſelves in a proper diſpoſition for attacking the enemy, or defending themſelves with the moſt advantage.

EVOLVULUS, in *Botany*, a genus of the *pentandria tetragynia* claſs, having a five-leaved calyx, a rotated corolla divided into five ſegments, a three-leaved capſule, and a ſingle ſeed. There are five ſpecies.

EUONYMOIDES, *in Botany*. See STAFF-*tree*.

EUONYMUS, in *Botany*. See SPINDLE-*tree*.

EUPATORIUM, in *Botany*. See *Hemp* AGRIMONY.

EUPETALOS, in *Natural Hiſtory*, the name of a gem deſcribed by the ancients as famous for its variety of colours. Pliny, lib. xxxvii. cap. 10. tells us, that it ſhewed at once blue, fire-colour, red-lead colour, and yellow. It ſeems to have been the opal, and that Pliny's deſcription of it in this place was taken from ſome author he did not perfectly underſtand, as is the caſe in many of his accounts from the Greeks.

EUPHEMISMUS, Εὐφημισμὸς, of εὖ, *well*, and φημι, I *ſpeak*, in *Rhetoric*, a figure which expreſſes things in themſelves diſagreeable and ſhocking, by terms implying the contrary quality; thus, the Pontus or Black Sea, having the epithet of ἄξενος (i. e. *inhoſpitable*) given it on account of the ſavage cruelty of thoſe who inhabited the neighbouring countries; this name, by *Euphemiſm*, was changed into that of *Euxinus*. Thus Ovid. Triſt. lib. iii. eleg. 13.

Dum me terrarum pars pene noviſſima Ponti
Euxinus falſo nomine dictus habet.

In which ſenſe it only makes a ſpecies of irony. But every *euphemiſm* is not irony; for we ſometimes uſe improper and ſoft terms in the ſame ſenſe with the proper and harſh. See Voſſ. Rhet. lib. iv. cap. 186, ſeq.

EUPHONIC *accent*. See ACCENT.

EUPHONY, Εὐφωνία, in *Grammar*, an eaſineſs, ſmoothneſs, and elegancy of pronunciation.

The word is formed of εὖ, *bene*, *well*, and φωνὴ, *vox*, *voice*. Quintilian calls *euphonia*, *vocalitas*; Scaliger, *facilis pronuntiatio*.

Euphonia is properly a kind of figure whereby we ſuppreſs a too harſh letter, or convert it into a ſmoother, contrary to the ordinary rules. There are examples enough in all languages.

EUPHORBIA, in *Botany*. See SPURGE.

EUPHORBIUM, Εὐφόρβιον, in *Pharmacy*, a gum brought from Africa, in little roundiſh pieces, whitiſh when new, and yellowiſh when old; very pungent to the taſte and void of ſmell.

The principal uſe of *euphorbium* is external; it is a great ingredient in divers reſolutive plaſters as well as in tincture and powder for ſtopping of gangrenes, cleanſing of foul ulcers, and exfoliating carious bones.

Internally taken, it is a purgative; but ſo violent a one, that it is almoſt out of uſe, as tearing off the neceſſary mucus, or covering of the ſtomach or bowels, and occaſioning dyſenteries. Yet, we are told the Africans uſe it

it very commonly; but they firſt quench its fire in purſlain-water.

Its powder is a violent ſternutatory, and to be uſed very cautiouſly, and never alone, but mixed with a ſmall quantity of ſome other powder, to guard againſt its intolerable acrimony.

The gum we call *euphorbium* is formed of the juice of a plant of the ſame name, pretty frequent in Mauritania, though the ſpecies of the plant has been greatly controverted. The generality of our lateſt botaniſts make it a thorny, ſucculent plant; and Mr. Profeſſor Hermannus calls it the *tithymalus Mauritanus aphyllos anguloſus & ſpinoſus*. Hort. Acad. Lug. Batav. 598.

The plant is the *euphorbia aculeata ſexcosta multangulari, ovalem ſeminalis* of Linnæus.

It has no leaves; but in lieu thereof puts forth along its ſtem a kind of long, prickly eyes, or buds; which buds yield that gummy juice, called *euphorbium officinarum*. See Brade. Hiſt. of Succul. Plants, dec. ii. p. 4. and dec. v. p. 12.

Some authors will have it, that the gum is drawn from the plant by inciſion; others, on the contrary, ſay it oozes ſpontaneouſly. The juice, we are told, is ſo very ſubtile and penetrating, that the perſon who taps the plant is forced to ſtand at a good diſtance, and make the inciſion with a long pike; otherwiſe it gets to the brain, and occaſions dangerous inflammations. It eaſes out in great abundance, and is gathered in ſheep's ſkin, wrapped round the plant.

Pliny tells us, that the firſt diſcovery of *euphorbium* is attributed to Juba king of Lybia, who denominated it from Euphorbus his phyſician, brother of Muſa, phyſician to Auguſtus. Enmuller aſſures us, that the plant which yielded the *euphorbium* of the ancients is now unknown to us; but if we follow Pliny's deſcription, the plant called *ſchaidis calli*, in the Hortus Malabaricus, muſt be the ancient *euphorbium*. This diſcovery is owing to Commelinus, a Diſpo-maſter of Amſterdam, and profeſſor of botany.

EUPHORY, ſignifies the ſame as EUCRACY.

EUPHRASIA, in *Botany*. See EYE-BRIGHT.

EUPHROSYNUM, in *Botany*, a name uſed by Pliny and ſome others for the common borrage. See BORRAGE.

EUPNŒA, of *ευ*, *well*, and *πνεω*, *I breathe*, in *Medicine*, is a right and natural reſpiration.

EUPORIA, of *ευ* and *πορος*, *paſſage*, in *Medicine*, is an eaſy preparation of medicines, or the eaſineſs of their operation.

EUPSYCHIANS. See EUNOMIORUPSYCHIANS.

EUREOS, in *Natural Hiſtory*, the name of a ſtone, deſcribed by Pliny, and ſeeming plainly to be the ſame with the tecolithus, which he mentions in another place, and to be the ſtone now called *lapis Judaicus*, and known at this time to be the petrified ſpine of a ſort of echinus marinus, or ſea urchin.

EURIPUS, *Ευριπος*, in *Hydrography*, properly ſignifies a certain ſtreight of the ſea between Bœotia and Eubœa, where the currents are ſo ſtrong, that the ſea is ſaid to ebb and flow ſeven times a day; in which place, as the ſtory commonly goes, Ariſtotle drowned himſelf out of chagrin, for not being able to account for ſo unuſual a motion.

EURIPUS has ſince become a general name for all ſtreights, where the water is in great motion and agitation.

The ancient circules had their *Euripi*, which were no other than pits or ditches, on each ſide of the courſe, into which it was very dangerous falling with their horſes and chariots as they ran races. The term *Euripus* was more particularly applied by the Romans to three canals or ditches which encompaſſed the circus on three ſides, and which were filled occaſionally, to repreſent naumachiæ or ſea-battles.

The ſame people called their ſmaller fountains or canals in their gardens *Euripoſes*; and their largeſt, as caſcades, &c. *Nibl.*

EUROCLYDON, of *Ευρος*, *eaſt-wind*, and *κλυδων*, *tempeſt*, is a ſpecies of wind, of which we have an account only in Acts xvii. 14. and concerning the nature of which critics have been much divided. Bochart, Grotius, Bentley, and others, ſubſtitute another reading, ſupported by the Alexandrian MS. and the Vulgate, viz. *Ευραυλων*, or *Ευροαυστρος*; but Mr. Bryant defends the common reading, and conſiders the *Euraculon*, i. e *Ευρος κλυζων*, as an eaſt-wind that cauſes a deep ſea or vaſt inundation. He maintains, in oppoſition to Dr. Bentley's reaſoning, who ſuppoſes that the mariners in the ſhip, the voyage of which is recited in this paſſage, were Romans, that they were Greeks of Alexandria, and that the ſhip was an Alexandrine ſhip, employed in the traffic of carrying corn to Italy; and therefore, that the mariners had a name in their own language for the particular typhonic or ſtormy wind here mentioned. He alſo ſhews from the paſſage itſelf, that the tempeſtuous wind called *Euroclydon*, beat (κατ' αυτης) upon the iſland of Crete; and therefore, as this is a relative expreſſion, referring to the ſituation of the perſon who ſpeaks of it, who was at that time to the windward or ſouth of it, the wind blew upon ſhore, and muſt have come from the ſouth or ſouth-eaſt; which, he adds, is fully warranted from the point where the ſhip was, and the direction it ran in afterwards, which was towards the north and north-weſt. Bryant's Obſervations, &c. 1767, p. 1, &c.

EURO *Auſter*.
EURO-*Notus*. } See WINDS.
EURUS.

EUROPEAN *Hours*. See HOUR.

EUROPEAN *Ocean*. See OCEAN.

EURYALE, in *Mythology*, one of the Gorgons, daughter of Phorcys, and ſiſter of Meduſa: ſhe was ſubject neither to old age nor death.

EURYDICE, in *Mythology*, the wife of Orpheus, who, flying from Ariſtæus that endeavoured to raviſh her, was ſlain by a ſerpent. Her huſband went down to the ſhades, and by the force of his muſic perſuaded Pluto and Proſerpine to give him leave to carry back his wife; which they granted, provided he did not look on her till he came to the light; but he, breaking the condition, was forced to leave her behind him.

EURYNOMIA, *Ευρυνομια*, in *Antiquity*, an anniverſary ſolemnity in honour of Eurynome, by ſome thought to be the ſame with Diana, by others one of Oceanus's daughters.

EURYTHMY, *Ευρυθμια*, in *Architecture, Painting*, and *Sculpture*, a certain majeſty, elegance, and eaſineſs, appearing in the compoſition of divers members, or parts of a body, building, or painting, and reſulting from the fine proportions thereof.

The word is Greek, and ſignifies literally a *conſonance*, or *fine agreement*, or, as we may call it, a *harmony of all the parts*, being compounded of *ευ*, *well*, and *ρυθμος*, *rhythmus*, *cadence*, or *agreement of numbers*, *ſounds*, or the like things. Vitruvius ranks *eurythmia* among the eſſential parts of architecture: he deſcribes it as conſiſting in the beauty of the conſtruction or aſſemblage of the ſeveral parts of the work, which renders its aſpect or whole appearance graceful; e. gr. when the height correſponds to the breadth, and the breadth to the length, &c.

"From theſe three ideas or deſigns, viz. orthography, "ſcenography, and profile, it is that *eurythmy, majeſtica*, "and *venuſta ſpecies ædificii*, do reſult, which creates that "agreeable harmony between the ſeveral dimenſions, ſo "as nothing ſeems diſproportionate, too *long* for this, "or too broad for that, but correſponds in a juſt and "regular ſymmetry, and conſent of all the parts with "the whole." Evelyn's Account of Archit. &c.

EUSEBES, the name of a ſpecies of marble mentioned by Pliny: he has given us no deſcription of it, but only tells us, that there was a ſeat made of it in the temple of Hercules at Tyre, from which the prieſts pretended that the gods uſed to ariſe.

EUSEBIANS, a denomination given to the ſect of Arians, on account of the favour and countenance which Euſebius, biſhop of Cæſarea, ſhewed and procured for them at their firſt riſe. See ARIANS.

EUSTATHIANS, a name given to the Catholics of Antioch in the fourth century, on occaſion of their refuſal to acknowledge any other biſhop beſide St. Euſtathius, biſhop of Sebaſtia in Armenia, depoſed by the Arians.

The denomination was given them during the epiſcopate of Paulinus, whom the Arians ſubſtituted for St. Euſtathius, about the year 330, when they began to hold their aſſemblies apart. About the year 350, Leontius of Phrygia, called the Eunuch, who was an Arian, and was put in the ſee of Antioch, deſired the *Euſtathians*, to perform their ſervice in his church; which they accepted; and the church of Antioch ſerved indifferently thus both for the Arians and Catholics.

This, we are told, gave occaſion to two inſtitutions, which have ſubſiſted in the church ever ſince: the firſt was pſalmody in two choirs; though Mr. Baillet thinks, that if they inſtituted an alternate pſalmody between two choirs, it was between two Catholic choirs, and not by way of reſponſe to an Arian choir. The ſecond was the doxology, *Glory be to the Father, and the Son, and the Holy Ghoſt*.

This conduct, which ſeemed to imply a kind of communion with the Arians, gave great offence to abundance of Catholics, who began to hold ſeparate meetings, and thus formed the ſchiſm of Antioch. Upon this the reſt, who continued to meet in the church, ceaſed to be called *Euſtathians*; and that appellation became reſtrained to the diſſenting-party.

St. Flavianus, biſhop of Antioch, in 381, and one of his ſucceſſors, Alexander, in 482, brought to paſs a coali-

tion or re-union between the *Eusebians* and the body of the church of Antioch, described with much solemnity by Theodoret, Eccl. lib. iii. cap 2.

EUSTATHIANS were also a sect of heretics in the fourth century, denominated from their founder Eustathius, a monk so foolishly fond of his own profession, that he condemned all other conditions of life. Whether this Eustathius was the same with the bishop of Sebastia and chief of the Semi-arians, is not easy to determine.

He excluded married people from salvation; prohibited his followers from praying in their houses, and obliged them to quit all they had, as incompatible with the hopes of heaven.

He drew them out of the other assemblies of Christians to hold secret ones with him, and made them wear a particular habit: he appointed them to fast on Sundays; and taught them, that the ordinary fasts of the church were needless, after they had attained to a certain degree of purity which he pretended to. He shewed great horror for chapels built in honour of martyrs, and the assemblies held therein.

Several women, seduced by his reasons, forsook their husbands, and abundance of slaves deserted their masters houses.

He was condemned at the council of Gangra, in Paphlagonia, held between the years 326 and 341. Socr. lib. ii. cap. 43. and Sozom. lib. iv. cap. 24. Hard. Concil. Coll. tom. i. p. 530.

EUSTYLE, formed of *ev*, *bene*, *well*, and *στυλος*, *column*, in *Architecture*, a kind of edifice, where the columns are placed at a moft convenient diftance one from another, the intercolumniations being all juft two diameters and a quarter of the column, except thofe in the middle of the fronts, before and behind, which are three diameters diftant. See *Tab. Archit. fig.* 40. C.

The *euftyle* is a medium between the pycnoftyle, and araeoftyle.

Vitruvius, lib. iii. cap. 2. obferves, that the *euftyle* is the moft approved of all the manners of intercolumniation, and that it furpaffes all the reft in conveniency, beauty, and ftrength.

EUTERPE, of *ev*, *well*, and *τερπω*, *I delight*, in *Mythology*, one of the nine Mufes, which preftded over wind-inftruments: the is reprefented with a crown of flowers, playing on a double flute, with Cupid at her knees. To her the invention of tragedy is afcribed.

EUTHYMIA, *Εὐθυμια*, among the Greeks, fignified fuch a difpofition, or ftate of the mind, as could not be ruffled either by good or bad fortune, by ficknefs or health, good or evil. Mem. Acad. Infeript. vol. xiv. p. 131.

EUTYCHIANS, ancient heretics, who denied the duplicity of natures in Chrift; thus denominated from Eutyches, the archimandrite, or abbot of a monaftery at Conftantinople, who began to propagate his opinion A. D 448.

The averfion Eutyches bore to the herefy of Neftorius, threw him into another extreme, not lefs dangerous than that he fo warmly oppofed; though fome paffages in St. Cyril, which raifed the unity of the perfon of Jefus Chrift very high, contributed, likewife, to his delufion.

At firft he held, that the *Logos*, *Word*, brought his body down with him from heaven; which was a near approach to the herefy of Apollinarius; and, though he afterwards teftified the contrary, in a fynod at Conftantinople, wherein he was condemned, yet he could not be brought to acknowledge, that the body of Jefus Chrift was confubftantial with ours.

In effect, he did not feem quite ftedy and conftftent in his fentiments; for he appeared to allow of two natures, even before the union; which was apparently a confequence he drew from the principles of the Platonic philofophy, which fuppofes a pre-exiftence of fouls; accordingly, he believed that the foul of Jefus Chrift had been united to the divinity, before the incarnation; but then he allowed no diftinction of natures in Jefus Chrift fince his incarnation.

See the differtation of H. Hanlouin, De Sacramento Altaris; wherein that Jefuit endeavours to unfold all the fentiments of the *Eutychians*.

This herefy was firft condemned in a fynod held at Conftantinople, by Flavian, in 448, approved by the council of Ephefus, called *Conventus latronum*, in 449, and re-examined and fulminated, in the general council of Chalcedon, in 451. The legates of pope Leo, who affifted at it, maintained, that it was not enough to define, that there were two natures in Jefus Chrift, but inftfted ftrenuoufly, that, to remove all equivocations, they muft add thefe terms, *without being changed, or confounded, or divided*.

The herefy of the *Eutychians*, which made a very great progrefs throughout the Eaft, at length became divided into feveral branches. Nicephorus makes mention of no fewer than twelve; fome called *Phantaftæ*, or *apparentes*, as only attributing to Jefus Chrift, a phantom, or appearance of flefh, and no real flefh; others *Theodofiani*, from Theodofius, bifhop of Alexandria; others *Jacobites*, from one James, *Jacobus*, of Syria; which branch eftablifhed itfelf principally in Armenia, where it ftill fubfifts. Others were called *Acephali*, q. d. *without heads*; and *Severians*, from a monk called Severus, who feized on the fee of Antioch in 513.

Thefe laft were fubdivided into five factions, viz. *Agnoetæ*, who attributed fome ignorance to Jefus Chrift; the followers of Paul; Maximus, that is the *black Angelites*, thus called from the place where they were aflembled; laftly, *Adelites*, and *Cononites*.

EUTYCHIANS was alfo the name of another fect, half Arian, half Eunomian; which arofe at Conftantinople, in the fourth century.

It being then a matter of mighty controverfy among the Eunomians at Conftantinople, whether or no the Son of God knew the laft day and hour of the world, particularly with regard to that paffage in the gofpel of St. Matthew, chap. xxiv. ver. 36. or, rather, that in St. Mark, xiii. 32. where it is expreffed, that *the Son did not know it, but the Father only*; Eutychius made no fcruple to maintain, even in writing, that the Son did not know it; which fentiment difpleafing the leaders of the Eunomian party, he feparated from them, and made a journey to Eunomius, who was then in exile.

That heretic acquiefced fully in Eutychius's doctrine, and admitted him to his communion; Eunomius dying foon after, the chief of the Eunomians at Conftantinople refufed to admit Eutychius; who, upon this, formed a particular fect of fuch as adhered to him, called *Eutychians*.

This fame Eutychius, with one Theophronius, as was faid in Sozomen's time, were the occafions of all the changes made by the Eunomians in the adminiftration of baptifm; which conftfted, according to Nicephorus, in only ufing one immerfion, and not doing it in the name of the Trinity, but in memory of the death of Jefus Chrift.

Nicephorus calls the chief of that fect not Eutychius, but Eupfychius, and his followers Eunomiocupreffians.

EWAGE, *Ewagium*, in our *Old Writers*, the fame with *aquage*, which is paid for water-paffage. It is derived from the French *eau*, *water*.

EWE, the Engliffh name for a female SHEEP.

EWRY, an office in the king's houfhold, where they take care of the linen for the king's table; lay the cloth, and ferve up water in filver *ewers* after dinner, whence the office takes its name.

EXACERBATION, the fame as PAROXYSM.

EXACHORD. See HEXACHORD.

EXACTION, in *Law*, a wrong done by an officer, or one pretending to have authority; in taking a reward, or fee, for that in which the law allows not of any.

The difference between *exaction* and extortion, conftts in this; that extortion is, where the officer takes more than his *duty*; and *exaction*, where he wrefts a fee, or reward, where none is due.

EXACTIS, in *Natural Hiftory*, a name given by Linnæus, and fome other authors, to a fpecies of ftar-fifh, of the more branched kind, whofe rays are fix in number, when they firft part from the body, but very foon branch out into a great number more. See STAR-*fifh*.

EXACTOR *regis*, in *Law*, the king's exactor, or collector. Sometimes it is taken for the fheriff. But generally, *quicunque publicas pecunias, tributa, vectigalia & fifci jura admittit exigitve, propriè nuncupatur exactor regis*.

EXACUM, in *Botany*, a genus of the *tetrandria monogynia* clafs: the calyx has four leaves; the corolla is divided into four fegments, and has a globofe tube; the capfule is bilocular, marked with two furrows, opens at the top, and contains many feeds. There are two fpecies.

EXAGON. See HEXAGON.

EXÆRESIS, *Ἐξαιρεσις*, of *ἐξαιρω*, *I take off*, in *Surgery*, an operation, whereby fomething foreign, ufelefs, and even pernicious, is taken from the human body.

The *exæreſis* is performed two ways; by extraction, when fomething formed in the body is drawn out of the fame; and by detraction, when fomething is taken away, that had been introduced into the body, from without. See LITHOTOMY, &c.

EXAGGERATION, in *Rhetoric*, a figure whereby we enlarge or heighten things; making them appear more than they really are, whether as to goodnefs, badnefs, or other qualities.

The word is formed of the Latin *exaggero*, *I aggerate*; which is a compound of *ex* and *agger*, a *mound*, or *elevation of earth*. See HYPERBOLE.

EXAGGERATION, in *Painting*, is a method of repreſenting things, wherein they are loaded too much, or marked too

too strongly; whether in respect of the design, or the colouring, or the position of the object.

Exaggerating differs from caricaturing; in that the latter perverts, or gives a turn to the features, &c. of a face, which they had not; whereas the former only improves, or heightens, what they had.

The latter is a kind of burlesque on the object, and is generally meant to ridicule: the former is usually an exalting or enlivening of the beauties of the object, beyond what nature allows. The painter is obliged to have recourse to an *exaggeration* of colours, both on account of the surface of his ground, the distance of his work, and of time, and the air, which diminish and weaken the force of the colours; but this *exaggeration* must be conducted in such manner, as not to put the objects out of their natural characters.

EXALTATION, *Elevation*, is chiefly used in a figurative sense, for the raising or advancing a person to some ecclesiastical dignity; and particularly to the papacy.

The term *exaltation* is, in some measure, appropriated to the pope; and expresses his INAUGURATION, coronation, taking possession, and the beginning of his pontificate.

EXALTATION *of the Cross*, EXALTATIO CRUCIS, is a feast of the Romish church, held on the fourteenth of September; in memory, as is generally supposed, of that, that the emperor Heraclius brought back the true cross of Jesus Christ, on his shoulders, to the place on mount Calvary, from which it had been carried away fourteen years before, by Cosroes, king of Persia, at his taking of Jerusalem, under the reign of the emperor Phocas. See CROSS.

The cross was delivered up by a treaty of peace made with Siroe, Cosroes' son. This institution of this treaty is commonly said to have been signalized by a miracle: in that Heraclius could not stir out of Jerusalem with the cross, while he had the imperial vestments on, enriched with gold, and precious stones; but bore it, with ease, in a common dress.

But, long before the empire of Heraclius, there had been a feast of the same denomination observed both in the Greek and Latin churches, on occasion of what our Saviour said in St. John xii. 32. *And I, if I be exalted, or lifted up, will draw all men unto me.* And again, in ch. viii. ver. 28. *When ye have exalted, or lifted up, the Son of man, then shall ye know that I am he.* F. Du Soulier assures us, that M. Chastelain was of opinion, this feast had been instituted, at least at Jerusalem, two hundred and forty years before Heraclius.

The feast of the dedication of the temple built by Constantine was held, says Nicephorus, on the fourteenth of September, the day on which the temple had been consecrated, in the year 335: and this feast was also called the *exaltation of the cross*, because it was a ceremony therein, for the bishop of Jerusalem to ascend a high place, built by Constantine for that purpose, in manner of a pulpit, called by the Greeks, *the sacred mysteries of God*, or *the holiness of God*, and there hoist up the cross, for all the people to see it.

EXALTATION, in *Physics*, denotes the act, or operation, of elevating, purifying, fixating, or perfecting, any natural body, its principles and parts; also the quality, or disposition, which bodies acquire by such operation.

The term *exaltation* has been peculiarly affected by the chemists and alchemists; who, imagining it to have some extraordinary emphasis, are employing it on every occasion.

EXALTATION, in *Astrology*, is a dignity which a planet acquires in certain signs, or parts, of the zodiac; which dignity is supposed to give it an extraordinary virtue, efficacy, and influence. The opposite sign, or part of the zodiac, is called the dejection of the planet.

Thus, the 15th degree of Cancer is the *exaltation* of Jupiter, according to Albumazar, because it was the ascendant of that planet at the time of the creation; that of the sun is in the 19th degree of Aries; and its dejection in Libra; that of the moon is in Taurus, &c. Ptolemy gives the reason of this in his first book De Quadrup.

EXAMEN, or EXAMINATION, an exact and careful search, or inquiry, in order to discover the truth, or falsehood, of a thing.

Self-EXAMINATION is a point much insisted on by divines, and particularly the ancient fathers, by way of preparation to repentance. St. Ignatius reduces it to five points; viz. 1. A returning of thanks to God for his benefits. 2. A begging of grace and light, to know and distinguish our sins. 3. A running over all our actions, occupations, thoughts and words, in order to learn what has been offensive to God. 4. A begging of pardon, and conceiving a sincere sorrow for having displeased him. And, 5. Making a firm resolution not to offend him any more; and taking the necessary precautions to preserve ourselves from it.

EXAMILION, &c. See HEXAMILION, &c.

EXAMINERS, in *Chancery*, are two officers, whose business is to *examine*, on oath, the witnesses produced on both sides, upon such interrogatories as the parties to the suit do exhibit for the purpose.

EXAMPLE, in *Rhetoric*, denotes an imperfect kind of induction, or argumentation; whereby it is proved, that a thing which has happened on some other occasion, will happen again, on the present one, from the similitude of the cases.

EXANNUAL *Roll*. In the old way of exhibiting sheriff's accounts, the illeviable sums and desperate debts were transcribed into a roll, under this name; which was yearly read, to see what might be gotten by it.

EXANTHEMA, formed of *ἐξανθεω*, *I flower*, in *Medicine*, a preternatural eruption, or efflorescence, on the skin.

Exanthemata are of two kinds; the one only a discolouring of the skin; such as the measles, the purple spots in malignant fevers, &c. The other are little eminences, or papillæ, standing out from the skin; such are pustules, small-pox, &c.

EXARCH, Εξαρχος, in *Antiquity*, an appellation given, by the emperors of the East, to certain officers sent into Italy, in quality of vicars, or rather prefects, to defend that part of Italy which was yet under their obedience; particularly the city of Ravenna, against the Lombards, who had made themselves masters of the greatest part of the rest.

The residence of the *exarch* was at Ravenna; which city, with that of Rome, were all that was left the emperors.

The first *exarch* was the patrician Boetius, famous for his treatise, De Consolatione Philosophiæ; appointed in 568, by the younger Justin. The *exarchs* subsisted about a hundred and eighty-five years, and ended in Eutychius; under whose *exarchate* the city of Ravenna was taken by the Lombard king Astulphus, or Astolphus.

F. Popebroch, in his Propylæum ad Acta Sanct. Maii, has a dissertation on the power and office of the *exarch* of Italy, in the election and ordination of the pope.

The emperor Frederic created Heraclius, archbishop of Lyons, a descendant of the illustrious house of Montbouffier, *exarch* of the whole kingdom of Burgundy; a dignity, till that time unknown any where but in Italy, particularly in the city of Ravenna. Menestrier. Hist. de Lyons.

Homer, Pliny, and other ancient authors, give, likewise, the name *exarchus* to the choragus, or master of the singers, in the ancient choruses, or him who sung first; the word *ἀρχω*, or *ἀρχομαι*, signifying equally *to begin*, and *to command*.

EXARCH *of a diocese* was, anciently, the same with *primate*. This dignity was inferior to the patriarchal, yet greater than the metropolitan.

EXARCH also denotes an officer, still subsisting in the Greek church; being a kind of deputy, or legate *a latere* of the patriarch, whose office it is to visit the provinces allotted him, in order to inform himself of the lives and manners of the clergy; take cognizance of ecclesiastical causes; the manner of celebrating divine service; the administration of the sacraments, particularly confession; the observance of the canons; monastic discipline; affairs of marriages, divorces, &c. but, above all, to take an account of the several revenues which the patriarch receives from several churches; and, particularly, as to what regards the collecting of the same.

The *exarch*, after having greatly enriched himself in his post, frequently rises to the patriarchate itself.

EXARCH is also used, in the *Eastern Church Antiquity*, for a general, or superior over several monasteries; the same that we otherwise call archimandrite; being exempted, by the patriarch of Constantinople, from the jurisdiction of the bishops; as are now the generals of the Romish monastic orders.

In 493, Sabas was established *exarch*, or chief, of all the anchorets within the territory of Jerusalem. Du Bois.

EXARTICULATION, a DISLOCATION of some of the jointed bones; or a breach of articulation. See LUXATION.

EXAUCTORATIO, among the Romans, differed from *missio*, or a discharge. In the latter, the soldiers were quite dismissed from the service; and this was done after they had served twenty years: but in the former case, they only left their pay, being still kept under their colours or *vexilla*, though not under the *eagle*, *aquila*, which was the standard of the legion. Whence, instead of *legionarii*, they were called *subsignani*, and were still retained till they had either served out their time, or had land assigned them. The *exauctoratio* commonly took place, after they had served seventeen years.

EXCALCEATION, *ex*, *off*, and *calceus*, *shoe*, *discalceation*, or the act of putting off the shoes.

Among the Hebrews there was a particular law, whereby a wi-

a widow, whom her husband's brother *refused* to marry, had a right to summon him into a court of justice; and, upon his refusal, might *excoriate* him, i. e. pull off one of his shoes, and spit in his face; which were both actions of great ignominy among that people.

The house of the person who had undergone them, was, thenceforward, called the house of the *excoriated*.

EXCAMBIATOR. See ESCAMBIO, and EXCHANGE.

EXCAVATION, formed of *ex*, and *cavus*, *hollow*, or *cave*, a *pit*, &c. the act of hollowing, or digging a cavity, particularly in the ground.

The *excavation* of the FOUNDATIONS of a building, by the Italians called *escavazione*, is settled, by Palladio, at a fifth part of the height of the whole building: unless there be cellars under ground, in which case he would have it somewhat more.

EXCELLENCY, a quality, or title of honour, given to ambassadors, and other persons, who are not qualified for that of highness, as not being princes; and yet are to be elevated above the other inferior dignities.

In England, and France, the title is now peculiar to ambassadors; but it is very common in Germany and Italy.

Those to whom it was first appropriated were the princes of the blood, of the several royal houses; but they quitted it for that of highness, upon several great lords assuming *excellency*.

The ambassadors have only borne it since the year 1593, when Henry IV. of France, sent the duke de Nevers ambassador to the pope, when he was first complimented with *excellency*. After that, the same appellation was given to all the other ambassadors residing at that court; from whence the practice spread through the other courts.

The ambassadors of Venice have only had it since the year 1630, when the emperor and king of Spain consented to allow it them.

The ambassadors of the crowned heads, dispute the giving of that title to the ambassadors from the princes of Italy; where the practice is not established.

The court of Rome never allows the quality of *excellency* to any ambassador who is a churchman, as judging it a secular title. The common rules and measures of *excellency* are a little variable, with respect to the court of Rome. The ambassadors of France, at Rome, anciently gave the title of *excellency* to all the relations of the pope then reigning; to the Constable Colonna; to the duke of Bracciano, and the eldest sons of all those lords; as also the dukes of Savelli, Cesarini, &c. But they are now more reserved in this respect; though they still honour all the Roman princesses with *excellency*.

The court of Rome, in their turn, and the Roman princes, bestow the same title on the chancellor, ministers, and secretaries of state, and presidents of the foreign courts of France; the presidents of the councils in Spain; the chancellor of Poland; and those of the first dignities of other states, if they be not ecclesiastics.

The word *excellency* was, anciently, a title of kings and emperors; accordingly Anastasius the library-keeper calls Charlemagne his *excellency*. The same title is still given to the senate of Venice; where, after saluting the doge under the title of *serenissima*, the senators are addressed under those of your *excellencies*. The Liber Diurnis Pontif. Rom. gives the title *excellency* to the exarch and patricians.

The Italian and French have improved on simple *excellency*; and made *excellentissimo*, and *excellentissime*, which have been bestowed on certain popes, kings, &c.

EXCELSIS, See GLORIA *in excelsis*.

EXCENTRIC, in *Geometry*, is applied where two circles, or spheres, though contained, in some measure, within each other, yet have not the same centre; and, consequently, are not parallel; in opposition to *concentric*, where they are parallel, having one and the same common centre.

The sun's orbit is *excentric*, with regard to the globe of our earth: Mars is very *excentric*, with regard to the sun; that is, his motion is about a very different centre.

EXCENTRIC, in the *New Astronomy*, or *excentric circle*, is a circle; as PDAE (*Tab. Astronom. fig.* 1.) described from the centre of the orbit of the planet C, with half the axis CE, as a radius.

EXCENTRIC, or *excentric circle*, in the ancient Ptolemaic *Astronomy*, was the very orbit of the planet itself, which it was supposed to describe about the earth, and which was conceived *excentric* thereto; called also the DEFERENT.

In lieu of *excentric circles* round the earth, the moderns make the planets describe elliptic orbits round the sun; which accounts for all the irregularities of their motions, and their different distances from the earth, &c. more justly and naturally.

EXCENTRIC, *anomaly of the*, is an arch of the *excentric circle*; as AK, intercepted between the aphelion A, and the right line KL, which, passing through the centre of the planet K, is drawn perpendicularly to the line of the apsides AP.

EXCENTRIC *equation*, in the *Old Astronomy*, is an angle made by a line drawn from the centre of the earth, with another drawn from the centre of the *excentric*, to the body, or place, of any planet; the same with the prosthaphæresis, and equal to the difference (accounted in an arch of the ecliptic) between the sun's, or a planet's, real, and apparent place. See EQUATION *of the centre*.

EXCENTRIC *place of a planet*, in its orbit, is the PLACE wherein the planet is seen from the sun.

EXCENTRIC *place*, in the ecliptic, is the point of the ecliptic to which the planet, viewed from the sun, is referred.

This coincides with the heliocentric place.

EXCENTRICITY, the distance between the centres of two circles, or spheres, which have not the same centre.

EXCENTRICITY, in the *Old Astronomy*, is the distance of the centre of the orbit of a planet from the centre of the earth.

That the five planets have such an *excentricity*, is allowed on all sides, and may be evinced from several considerations; chiefly this, that Saturn, Jupiter, Mars, Venus, and Mercury, at sometimes appear larger, and at others less; which can only proceed from hence, that their orbits being *excentric* to the earth, in some parts thereof they are nearer us, and in others more remote: but as to the *excentricities* of the sun and moon, some dispute has been made.

Many of the moderns hold, that the sun and moon appear sometimes larger, and sometimes less; not that they are nearer us at one time than another, but because they are viewed through different columns of air, which, producing a difference in the refraction of their light, may occasion those different appearances. Accordingly, we find very sudden alterations of the apparent magnitude of the moon, where nothing but a change in the air can take place.

Thus Kepler, on the 2d of March, in the year 1588, found the moon's apparent diameter 31 minutes, presently after 32′ 2″, then 30′ 3″; and the preceding day it had been 33′. And again, on the 22d of February, 1591, he observed the moon's diameter twice 31′, six times 32′, seven times 33′, and six times 34′.

They add, that when the sun and moon are in the southern signs, and consequently lower, being then seen through a longer column of dense air, they must appear bigger; consequently, in the winter-time, when the sun is in Capricorn, being seen through a greater quantity of air, he must appear larger than in summer, when, being nearer our zenith, the quantity of air he is seen through is less. And the like may be said of the moon.

But others take the *excentricities* of the sun and moon to be sufficiently proved, from eclipses; from the moon's greater and less parallax, at the same distance from the zenith; and from the sun's being observed to continue longer in the northern hemisphere than in the southern; viz. 186 or 187 days in the first, and only 178 or 179 days in the latter.

If we suppose the mean distance of every planet from the sun to be divided into 1000 equal parts, the *excentricities* of their orbits, both in such parts, and in English miles, will be as follow: Mercury's 210 parts, or 7,730,000 miles; Venus's 7 parts, or 482,000 miles; the earth's 17 parts, or 1,018,600 miles; Mars's 93 parts, or 13,486,000 miles; Jupiter's 48 parts, or 23,760,000 miles; Saturn's 55 parts, or 48,940,000.

EXCENTRICITY, in the *New Astronomy*, is the distance of the centre of the orbit of a planet, as C, from the centre of the Sun S, i. e. the distance between the centre of the ellipsis and the focus thereof; called also *simple* or *single excentricity*.

If the greatest EQUATION *of the centre* be given, the *excentricity* of the earth's orbit may be found by the following proportion: as the diameter of a circle in degrees is to the diameter in equal parts, so is the greatest equation of the centre in degrees to the *excentricity* in equal parts: thus circumference 3,1415926 : 1 its diameter : : 360° : 114°,591599, the diameter in degrees; and if the greatest equation of the centre be 1° 55′ 33″ = 1°,9268166, &c. we shall have 114°,591599 : 1,00, &c. : : 1,9268166 : 0,168061, the *excentricity*.

Hence 1,016806 (= 1,000000 + 0,016806) = the aphelion distance:

And 0,983194 (= 1,000000 − 0,016806) = the perihelion distance. Robertson's Elem. of Navig. book v. p. 286.

EXCENTRICITY, *double*, is the distance between the two foci in the ellipsis; which is equal to twice the *single excentricity*.

To find the *excentricity* of the sun: since the sun's greatest apparent semidiameter is to his least, as 32′ 43″ to 31′ 38″,

or as 1963 to 1898; the sun's greatest distance from the earth will be to his least as 1963 to 1898. Since then PS+SA=PA=1963 (*Tab. Astron. fig.* 1.); the radius of the *eccentric* CP will be found 1930; and consequently SC=PC−PS=32. Wherefore CP being 10000, CS will be found=165,8.

Hence, as the earth's *eccentricity* SC is so small a part of the radius of the *eccentric* CP, the earth's elliptic orbit does not deviate much from a circular one; so that it is no wonder a calculus, made on the supposition of an exact circle, should answer near enough to observation.

EXCEPTION, something reserved, or set aside, and not included in a rule.

It is become proverbial, that there is no rule without an *exception*: intimating, that it is impossible to comprehend all the particular cases under one and the same maxim. But it is dangerous following the *exception* preferably to the rule.

EXCEPTION, in *Law*, is a stop or stay to an action.

The term is used indifferently, both in the civil and common law; and in each, *exceptions* are divided into *dilatory* and *peremptory*.

In law proceedings, *exception* is a denial of a matter alledged to bar to the action; and in chancery it is that which is alledged against the sufficiency of an answer, &c. *Exceptions*, in a general sense, includes all the kinds of defence, or vindication, which a person, against whom a process is brought, makes use of to prevent or retard its effect.

The civilians reckon three kinds of *exceptions*; viz. *declinatory*, whereby the authority of the judge, or court, is disallowed; *dilatory*, intended to defer, or prevent the thing from coming to an issue; and *peremptory*, which are proper and pertinent allegations, founded on some prescription that stands for the defendant; as want of age, or other quality, in the party; or other matter, that may be decided, without entering into a full discussion of the merits of the cause.

EXCEPTION *to evidence*, in *Law*, is where a demurrer is offered in any civil cause, on account of the insufficiency of the evidence given, and the court does not agree to it; in which case, the court, or judge are required to seal a *bill of exceptions*, by Stat. Westm. 2. 13 Edw. I. cap. 31. which is in the nature of an appeal, examinable in the next immediate superior court, upon a writ of error, after judgment given in the court below. See DEMURRER.

EXCEPTION *in deeds and writings*, is the saving of a particular thing out of a general one granted by deed, as a room, shop, or cellar, out of a house; a field, or timber trees out of land, &c. *Exceptions* of this kind must not exist the grant, nor be repugnant to it, or else they are void of course; yet there may be a kind of *exception*, or saving out of an *exception*, so as to make a thing as if never excepted; as where a lease is made of a rectory, excepting the parsonage house, saving to the lessee a chamber, this shall pass by the lease.

EXCEPTIVE *conjunction*. See CONJUNCTION.

EXCEPTIVE *proposition*, are those wherein something is affirmed of a whole subject, abating some one of the parts thereof, which is *excepted* by a particle, thence called an *exceptive* particle, or particle of *exception*.

Thus, "All the sects of the ancient philosophers, except the Platonists, held God to be corporeal. Cumberland's is inexcusable in respect of every thing, but time."

EXCESS is distinguished into *natural* and *moral*: the *first*, is a part whereby one quantity is greater than another.—Thus, we say, this line is longer than that; but the *second* is reconsiderable.

The *latter*, is an intemperance, or going beyond the just bounds and measures prescribed for any thing. Thus, we say, *excess* in wine, women, &c. is prejudicial to the health.

EXCHANGE, in *Arithmetic*, is the reduction of different coins, or any denominations of money, whether there be real coins answering to them, or no, from one to another; or the method of finding how many of one species, or denomination, are equal in value to a given number of another; in order to which it is necessary to know the value of the coins and monies of account of different countries, and their proportion to each other, according to the settled rate of *exchange*. See COIN. The several operations in this case are only different applications of the RULE *of three*.

Ex. 1. England *exchanges* with France on the crown or *ecu* of three livres Tournois, allowing a certain number of pence sterling, more or less according to the rate of *exchange*, for this crown. Accounts are kept in France in *livres*, *sols*, and *deniers*. See COIN. Suppose then that a remittance is made from Paris to London of 1006 livres 14 sols, at 29*d.* sterling *exchange*, what is the amount in pounds, &c.? Divide the livres, sols, and deniers by 3, in order to reduce them into French crowns; then multiply the crowns by 29, the number of pence in a crown, and take the aliquot parts for the fractional parts, according to the subdenominations of the integers, or reduce them into decimals, and reduce the pence into shillings and pounds as below:

Divide by 3. 1006 . 14

Cr. 335 . 11.4

Mult. by 29

3015
670
14½
1
½

1219732

20812

40*l.* 11*s.*

When sterling money is to be reduced into French *exchange* crowns, reduce the sum given, and price of *exchange*, into the same denomination, and divide the former by the latter; and the crowns may be reduced to livres by multiplying the quotient by 3. The rate of *exchange* may be had by dividing the number of pence sterling by the number of French crowns, &c. in the given sum.

Ex. 2. England exchanges with Holland, Antwerp, and Hamburgh, at so many schellings, or stivins and groots Flemish per pound sterling. See *Dutch* COINS.

If London draws on, or remits to Amsterdam 8524 *l.* 12*s.* 6*d.* sterling, at 34 *s.* 4½ *gr.* Flemish per £ sterling, how many guilders, stivers, and pennings, must be paid or received in bank money in Amsterdam? i.e. if 1*l.* sterling gives 34 *s.* 4½ *gr.* what will 8524 *l.* 12*s.* 6*d.* give? Reduce the price of *exchange* to ½ groots, which, multiplied by the pounds sterling, gives the half groots contained in that sum; and, for the 12*s.* 6*d.* take 12*d.* as the half of 8524, and as 6*d.* as the fourth of that ancient; add the whole together, and the sum total is the number of half Flemish groots contained in the sterling money; which, being divided by 80, the half groots in a guilder, gives the answer in guilders; and the remaining half groots must be reduced to stivers and pennings. The operation is as follows:

l.	*s.*	*d.*		*Sc.*	*gr.*
8524	12	6	at	34	4½
8525				12	
34200				402	
1704				2	
68816		half gr.		825 =	*l.* sterling.

10*l.* = 402½
1*l.* 6*d.* = 103½

850 | 70341½

8792 guilders, 55 half groots ½. But 55 half groots are = 27½ groots = 13 stivers 12 pennings and ½ of the half groot = 2½ pennings; therefore the whole sum will be 8792 guilders 13 stivers 14½ pennings bank money.

This example may be easily reversed, by reducing the Dutch money, and price of *exchange*, into one denomination, and dividing the sum by the price; the quotient will give the answer in pounds sterling.

Ex. 3. England *exchanges* with Spain upon the piastre, or dollar of 8 rials, for an uncertain number of pence sterling. See *Spanish* COINS.

Suppose Cadiz remits to London 3537 dollars, 6 rials, at 49 per dollar, what will the remittance amount to in England? Multiply the dollars by 49½; take the half of 49½ for 4 rials, and the fourth for 2 rials; add the whole, which will give the sum in pence: thus,

3537 . 6
49½

121480
30942
20,½
10,¼

12) 1446054
210)120450.5½

602*l.* 10*s.* 5½*d.* sterling.

Ex. 4. England *exchanges* with Portugal on the *milreis*, and gives pence, more or less, for it. See *Portuguese* COINS.

Suppose that Lisbon, or Oporto, remits to London 4360 milreis, 183 rees, at 52 5d. ½ exchange, how much sterling must be paid in London for this remittance? The milreis, consisting of 1000 rees, these may be considered as decimals; then 52 being ½ of a pound, 5d. ½ of 52, and ½ the ½ of 52, divide accordingly, and sum up the whole, then reduce decimals of a pound into shillings, &c. The operation is as follows:

4360,183

52 = ½	·	1201,54175
5d. = ½	·	0,09021484 &c.
½ = ¼	·	11,360265 &c.

£.1213,83813 &c.
20

17,1563
12

6,756
4

3,024

The answer is 1213l. 17s. 6d. ¾ sterling.

The following examples illustrate the general method of setting the exchange between England and any other countries to which its commerce extends. But as considerable advantages may often be made by arbitrating the exchanges between different countries with accuracy, the following examples will explain the method of doing this in all common cases.

Ex. 5. Suppose London exchange on Amsterdam at 35—2¾
And on Paris at 32 4

What is the proportional arbitrated price between Amsterdam and Paris?

1 Paris crown = 32¼d. London.
240d. London = 422½ groots Amsterdam = 35 7. 12 ½ 2½
See Cor. 12.

Then if 240d. gives 422½ groots, what will 32¼d. give? But as the multiplication and division of quantities, partly integral and partly fractional, require a knowledge of vulgar and decimal fractions, which some men of business are not perfected in, there are methods which may be recurred to in practice, that will obviate such difficulties. It is well known, that if equal quantities are multiplied and divided by equal quantities, the numbers resulting from such operations will bear the same proportion to each other with the numbers first given.

Thus, in the preceding example, $\frac{422\frac{1}{2}\ gr. \times 32\frac{1}{4}d.}{240d.} =$

$$\frac{\frac{845}{2} \times \frac{129}{4} \times 8}{240 \times 8} = \frac{845 \times 257}{240 \times 32} = \frac{\frac{217165}{4}}{\frac{240}{8} \times 2 \times 8} = \frac{54291\frac{1}{4}}{48 \times 2 \times 8}$$

= 56 groots Amsterdam 2¼

Ex. 6. Let Paris exchange on London at 32¼
On Amsterdam at 56 9½

What is the proportional arbitrated price between London and Amsterdam?

1l. sterling = 240d.
32¼d. = 369½ groots.

$32\frac{1}{4}d. : 369\frac{1}{2} :: 240 : \frac{240 \times 369\frac{1}{2}}{32\frac{1}{4}}$ = (multiplying numerator and denominator by 368 and 8)

$$\frac{240 \times 8 \times 4743}{4 \times 129} = \text{(dividing both by 8 and 48)} \frac{4743 \times 5}{129 \times 2} = 221\tfrac{1}{2} \text{ groots}$$

= 35—3½.

Ex. 7. Let Amsterdam exchange on Paris at 56 9½.
On London at 35—4.

What is the proportional arbitrated price between London and Paris?

1 Paris crown = 56 9½ groots.
422½ groots = 240d. sterling.

$422\frac{1}{2}\ gr. : 240d. :: 369\frac{1}{2}\ gr. : \frac{240 \times 369\frac{1}{2}}{422\frac{1}{2}} =$

$$\frac{15 \times 369\frac{1}{2} \times 368 \times 2}{422\frac{1}{2} \times 2} \times \frac{96 \times 4743}{1692 \times 368} = \frac{15 \times 4743}{1692 \times 3} = \frac{71145}{1692 \times 3} =$$

$\frac{4743}{1692 \times 8} = 32\frac{1}{4}d.$ sterling.

Ex. 8. Suppose that 100l. sterling is circulated from London to Amsterdam at the price of exchange in the preceding examples, viz. at 35—½, how many guilders of Holland will this sum produce? 100l. sterling, at 422½ groots Amst. per £. sterling, will produce 1056—10 guilders of Amsterdam, by Ex. 5. Then 1056—10 guilders, circulated from Amsterdam to Paris, will produce at the arbitrated price of exchange, viz. 56 9½ groots per French crown, 747 crowns—1—7½ of France; and these crowns drawn home to London, at the above exchange of 32¼d. sterling, per French crown, will produce the same 100l. sterling. Whence it follows that if the real price of exchange, at the time when these computations are made, is more or less between Amsterdam and Paris than the exact arbitrated price, in example 7, one may draw home more or less than 100l. sterling.

In all transactions of this kind, the skilful merchant will watch the occasion to buy bills of exchange when they are cheapest, in order to dispose of them at such places, where, at the same time, they are dearest. See next article.

Exchange, *Permutation*, in *Commerce*, an agreement, whereby one thing is traded or given for another.

The first commerce carried on among men, was by exchanges, people furnishing each other mutually with what things they wanted; but such exchanges were clogged with two considerable difficulties. 1. On account of the unequal values of commodities; and, 2. Because every body had not just what might accommodate the person with whom he would exchange.

To remove these inconveniences, money was invented for a common medium; and instead of exchanging, buying and selling were introduced.

Yet there are nations among whom the primitive way of exchange still obtains; and even among the most civilized people, there are frequent occasions, in which they have recourse to this method. Such, for instance, is the trade of several cities of the North, and Baltic Sea, where the French exchange their wines and brandies for wood, metals, hemp, and furs.

The commerce of bills of exchange is, itself, a mere trading by exchanges, a truck of money for money.

Exchange, therefore, properly denotes the bargain, or trade of money, as carried on between one place and another, by means of bills of exchange, i.e. by giving money in one city, and receiving a bill to entitle the giver to receive the value in another city. See Bill of Exchange.

There is also another species, called *dry exchange*, or *sham*, or *usance exchange*, which consists in giving money at one place, to be repaid at after a certain time, in the same place, with a certain interest, which is usually more than common interest.

The customary or ordinary supplement for this is fictitious Usance, which is only a mere real borrowing money. The borrower draws a bill of exchange on any imaginary person, perhaps at Amsterdam, at one month's exchange, then gets it accepted, and delivers it to the lender. After the time elapsed comes a protest from Amsterdam for nonpayment, with the reexchange of the money from thence to London; all which with some little additional charges, postage at the walking of the bill, &c. the borrower must pay.

Exchange is also used for the profit which a merchant, negociant, or broker makes of a sum of money received, and for which a bill of exchange is drawn, payable in some other place, and by some other person: for the interest of his money, and the salary and reward of his negociation. This profit is exceedingly various; being sometimes 2, sometimes 3, 4, or even 10 and 15 per cent. according as the value of the species differs, or as money is more or less plentiful, or bills of exchange more or less scarce, in the places. This kind is ordinarily called *real exchange*, and sometimes *mercantile* or *round exchange*.

The price of exchange is regulated according to the course of the place where the bill is drawn, or that of the place where the remittance is to be made: some pretend that it is the city of Lyons gives the law, or rule, for the price of exchange to most of the other cities of Europe.

The word *exchange*, according to some, is derived from that perpetual alteration observed in the price of this exchange, which is sometimes higher and sometimes lower, there being encouragers determined to get, and determined to lose thereby; and sometimes nothing to be either got or lost, as is the case, when the exchange is at par.

From this diversity in the price of exchange, arises that common proverb, *Par exchange, joy of mind, exceeds marriage.* But the more natural way of deriving the word exchange is from this; that a man buys exchange for money for a bill; or that he changes present money for absent money; or changes his debts.

Exchange is not to be looked on as a trade, from which it differs, because in the one, the risque, or danger, lies on the person who borrows; and in the other, on him who lends. It likewise differs from interest, because exchange is not paid in proportion to the time, as interest is.

Exchange is also used in divers places for the principal reward for exchanging one sort, or species of money for another.

This is particularly called *small exchange*, *petit exchange*, &c.

EXCHANGE is sometimes also used for the AGIO, or profit allowed for the monies advanced in any one's behalf.

Exchange is a raising of the actual and momentary value of money. Silver as a metal has a value like all other merchandises and an additional value, as it is capable of becoming the sign of other merchandize. If it was no more than a mere merchandize, it would perhaps lose much of its nominal value. As a money, silver has a value which the prince in some respects can fix, but in others he cannot.

The prince establishes a proportion between a quantity of silver, as metal, and the same quantity, as money. He fixes the proportion between the several metals made use of as money; he establishes the weight and standard of every piece of money; in fine, he gives to every piece that ideal value already spoken of. We shall call the value of money in these four respects, its positive value, because it may be fixed by law.

The coin of every state has, besides this, a relative value as it is compared with the money of other countries. This relative value is established by the *exchange*, and greatly depends on its positive value. It is fixed by the current course of commerce, and by the general opinion and consent of merchants, but never by the decrees of the prince, because it is liable to excellant variations, depending on the accidental circumstances of trade, the money-transactions between nations, and the state of public credit, &c.

The several nations in fixing this relative value, are chiefly guided by that which possesses the greatest quantity of specie. If the law as much specie as all the others together, it is then most proper for the others to regulate their's by her standard; and this regulation between all the others, will nearly agree with the regulation made with this principal nation.

The relative abundance or scarcity of specie in different countries, forms what we called the course of *exchange*; and this plenty or scarcity, on which the mutability of the course of *exchange* depends, is not real but relative: e. g. when France has greater occasion for funds in Holland than the Dutch at having funds in France, specie is said to be common in France, and scarce in Holland: and *vice versâ*. See BALANCE of *Trade*.

We may observe, in general, that there is much specie in a place, when there is more specie than paper; there is little, when there is more paper than specie: and in order to judge of the scarcity or plenty of specie, we must know, for example, that if there are more bills from Holland than there are from France, then specie is scarce in France, and common in Holland; and therefore it becomes necessary that the *exchange* should rise, and the Dutch give more for specie of the same value in France, than the French for that of an equivalent value in Holland. When money of the same standard and weight in France yields more of the same standard and weight in Holland, the *exchange* is then said to be at PAR. Thus in the year 1744, the par was nearly as 54 gros to the French crown of three livres: when the *exchange* is above 54 gros, the French would say it is high; when below 54 gros, they say it is low. When the *exchange* is below par between one country and another, the former loses as debtor and buyer, and gains as creditor and seller. Thus if France owes Holland a certain number of gros, the more of these there are in a crown, the more crowns she has to pay; and as there must be the same number of gros to have the same quantity of merchandize, while the *exchange* is low, every French crown is worth fewer gros. On the contrary, if France is creditor for a certain number of gros, the less of them there are in a crown, the more crowns she will receive; and if France sells her merchandize in Holland for a certain number of gros, the more crowns will the society, in proportion as each crown contains fewer of these gros. The same reasoning will apply, *mutatis mutandis*, to the commercial intercourse of other countries, and to any par of *exchange*. It is evident, that a merchant may send his stock into a foreign country, when the *exchange* is below par, without injuring his fortune; because when it returns, he receives what he had left: but a prince, who sends only specie into a foreign country, which can never return, is always a loser. When merchants have great dealings to any country, the *exchange* there infallibly rises, on account of their numerous engagements, buying great quantities of merchandize, and receiving on foreign countries to pay for them. The arbitration of *exchanges* is an article of great importance in the discussion of this subject: this is a kind of trade, which two bankers or merchants manage by means of their bills upon different parts, at a conditional price and course of *exchange*.

In order to understand this branch of commerce, it is necessary to know how to reduce the several money of England into the foreign monies of *exchange* and of account of all places through Europe, according to the different courses of *exchange* established for these purposes; and *vice versâ*; and also those of other places, with which England has no direct established courses of *exchange*, but is under the necessity of making use of the intermediate changes of other places. The nature of the AGIO, and the manner of converting bank monies into current, and the reverse, should likewise be well understood. The method of reducing the foreign monies of Europe into those of every other distant country, according to the direct or intermediate *exchange*, should be thoroughly known: besides, it is necessary to know the intrinsic value of foreign monies, according to the most accurate assays that have been made for that purpose; and also the general natural causes of the rise and fall of the courses of *exchange* between one nation and one city, and another; which depend on the balance of trade being either in favour of or against such trading nation or city.

By an accurate observation and comparison of the courses of *exchange* between various countries and cities, the merchant will have an opportunity of profit, which should not escape his cognizance. He will find that they seldom ebb and flow in an exact equality of proportion, since the balance of trade differs between different nations. The greatest profit may be made by seizing the opportunity of drawing and remitting to certain places preferably to others. Further, when the *exchange* is lower than the specie of a country, a profit may be made by sending it abroad; when it is higher, there is a profit in causing it to return; but there is a case in which profit may be made, by sending the specie out of the kingdom, when the *exchange* is at par; that is, by sending it into a foreign country, to be received; when it returns, an advantage may be made of it, whether it be circulated in the country, or paid for foreign bills. See further on this subject, Poll. Dict. Com. articles *Arbitration* and *Exchange*.

EXCHANGE also denotes a public place, in most considerable cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, meet, on certain days, and at certain times thereof, to confer, and treat together of matters relating to *exchanges*, remittances, payments, adventures, assurances, freightments, and other mercantile negociations both by land and sea.

In Flanders, Holland, and several cities of France, these places are called *bourses*; at Paris and Lyons, *places des changes*; and in the Hanse towns, *colleges of merchants*.

These assemblies are held with so much exactness, and merchants and negociants are so indispensably required to attend at them, that a person's absence alone makes him be suspected of a failure or bankruptcy.

The most considerable *exchanges* in Europe, are that of Amsterdam; and that of London, called the Royal *Exchange*. But an account of the latter, see ROYAL *Exchange*.

The former is a large building, two hundred and thirty feet long, and a hundred and thirty broad, round which runs a portico, or portico, twenty feet wide. The columns of the portico, amounting to forty-six, are numbered, for the convenience of finding persons.

That of Antwerp was little inferior to either of them, till a variety of circumstances concurred to effect its ruin, and to transfer its trade to Amsterdam; the æra of this important event in commercial history is about the year 1585.

Even in the time of the ancient Romans there were places for the merchants to meet, in most of the considerable cities of the empire. That said by some to have been built at Rome in the year of the city 550, 203 years before our saviour, under the consulate of Appius Claudius, and Publius Servilius, was called *ante ad mercurium*; whereof it is pretended there are still some remains, called by the modern Romans *loggie*, the *loges* and now, usually, the *Piazza di S. George*.

This notion of a Roman *exchange* is supposed to be founded on the authority of Livy, whose words are as follow; viz. *Cernunt confestim aedilitati, ædes ad mercurii adem. Senatui si ea res ex sententia reipsi uti rerum dedicatio justa, pontificum decretum sit, comprecatio omnium, mercatorum cessatio esse videri justa.* Liv. lib. ii. But it muſt be here remarked, that *templum* never signified a building for a society in the purer ages of the Latin tongue; so that *collegium mercatorum templum* could not be rendered to build an *exchange* for the merchants, but to incorporate the merchants into a company. As Mercury was the god of traffick, this *adis Mercurii* seems to have been chiefly designed for the devotions of this company as corporation.

EXCHANGE, in *Law*, is a mutual grant of equal interest in lands or tenements, the one in *exchange* for the other; and in our common law it more particularly denotes the com-

compositions which the warrantie itself make the warrantee value for value, if the land warranted be recovered from the warrantee. Bratton lib. ii. See WARRANTY.

EXCHANGE, *the King's*, is the place appointed by the king for *exchange* of plate, or bullion for the king's coins. Three places have formerly been therein; but now there is only one, viz. that in the Tower of London, joined with the Mint.

EXCHANGE, *bill of*. See BILL of *Exchange*.

What we call *exchange*, is the *fine*, or premium of a second *exchange*, when a bill is granted. See RE-EXCHANGE.

EXCHANGE-*brokers*, are persons who make it their business to know the state of the course of exchange, to inform merchants how it goes, and to notify to those who have money to receive or pay beyond sea, who are proper persons for every one to employ their orders.

EXCHANGERS are those who return money beyond sea, by bills of *exchange*, &c. called anciently *alle exambiatores*, and *intercambiatores*.

EXCHEQUER, or simply CHEQUER, originally denotes a Chess-board, or a frame divided into sixty-four squares, of two colours, whereon to play at draughts, chess, &c. See CHESS, &c.

The word is formed from the French *echiquier*, which signifies the same. Hence, trees are said to be planted *exchequerwise*, or *quincunxwise*, when disposed so as to form *directe* figures resembling a *chequer*.

EXCHEQUER is more particularly used for a chamber, or apartment, in Westminster-hall, consisting of two parts; the *court of exchequer* and the *office exchequer*. See COURT of *Exchequer*.

EXCHEQUER-*bills* are a species of paper first established by Mr. Montague, in 1696, to supply the want of circulating cash, during the re-coinage at that period. They were then taken at the *exchequer* for all payments of the revenue, and, when re-issued, they were allowed 7*l.* 12*s.* *per cent.* interest. They have since been issued yearly; and the bank of England, ever since the year 1706, have been the contractors for their circulation, at a certain premium. The commissioners of the treasury are empowered, by various statutes, to borrow money, within a specific sum, limited by those statutes, by issuing *exchequer* bills on the credit of certain duties; which bills, by 12 Anne, cap. 11. & 12 Geo. I. cap. 11. bear an interest of 3*d.* a day *per cent.* payable to the bearers. These bills are numbered arithmetically, and registered accordingly, so that the principal sums may be paid off in course, and the interest shall be payable every three months. The said *exchequer* bills shall be current to all receivers and collectors of the customs, excise, or any revenue, and at the receipt of the *exchequer*; and as any of them are paid or lent into the *exchequer*, the officers there shall cause tallies to be levied and delivered to the payers or lenders, as if they had made such payments or loans in specie. If any *exchequer* bills be lost, upon affidavit before a baron of the *exchequer*, and certificate from him, and security given to pay the same if found, duplicates are to be made out; and when bills are defaced, new ones shall be delivered. Forging of these bills, or of the indorsements on them, is felony.

EXCHEQUER, *messenger of the*. See MESSENGER.

EXCHEQUER, *Book kept of the*, is a book under the keeping of the two chamberlains of the *exchequer*; said to have been compiled in 1175, by Gervais of Tilbury, nephew of king Henry II. and divided into several chapters.

Herein is contained a description of the court of England, as in that time, its officers, their ranks, privileges, wages, perquisites, power, and jurisdiction; and the revenues of the crown, both in money, grain, and cattle.

Here we find, that for one shilling, as much bread might be bought as would serve a hundred men a whole day; that the price of a fat bullock was only twelve shillings, and a sheep, four, &c. Lamy, p. 4. p. 304. See also DOMESDAY-*book*.

EXCIPIENT, in *Pharmacy*, a term used to express that ingredient in a compound medicine, the business of which is to receive all the rest; such is the conserve in electuaries, the syrup in julapes, &c.

EXCISE, a duty, or imposition, charged on beer, ale, cyder, liquors made to sale, and other commodities, within the kingdom of Great Britain, and town of Berwick upon Tweed.

The duty of *excise*, as well as the term, was first introduced in 1643, not afterwards granted to king Charles II. by act of parliament, in the year 1660, during the life of that prince: it has since been continued and augmented by diverse parliaments, under the several succeeding princes, and extended to Scotland.

The several commodities that are liable to the duty of *excise*, are ale, beer, cyder, perry, mum, metheglin, mead, sweets, verjuice, vinegar, candles, coaches, coffee, tea, and chocolate; glass, hops, leather, linen-cloth, silks and cottons; malt, paper, plate, salt, soap, spirituous liquors, starch, and hair-powder, and wire. See the several articles.

Besides the particular duties, there are three additional duties of 5 *per cent.* on all customed and excised goods, except candles, soap, malt, beer, and sider or perry, &c. by 19 G. III. c. 25. 21 G. III. c 17. and 22 G. III. c. 66.

The *excise* is one of the most considerable branches of the king's revenue. The amount of the *excise* in England, including the malt-tax, estimated at a medium of three years, ending in 1773, was 4,629,893*l.* and the expence of collecting, being the average of the years 1767 and 1768, when their produce was 4,531,075*l.* per ann. 6 *per cent.* of the gross produce, or 269,887*l.*; and in Scotland, estimated in the same manner, 95,270*l.* and the expence of collecting, being the medium of 1772 and 1773, and the difference between the gross and nett produce, 31 *per cent.* of the gross produce, or 43,254*l.* It was formerly farmed out, but is now managed for the king by nine commissioners, in England, who sit in the *general excise office*, receive the whole product of the *excise* of beer, ale, and other liquors, and malt, collected all over England, and pay it into the EXCHEQUER.

Their salary is 1000*l.* per annum each, and they are obliged by oath to take no fee, or reward, but from the king only. From the commissioners of *excise* there lies an appeal to four others, called *commissioners of appeals*. The commissioners of *excise* in Scotland are five, and each has a salary of 500*l.* per annum.

The number of officers employed in this branch of the revenue, is very great. Besides the commissioners above mentioned, and their subordinate officers, as registers, messengers, &c. there is an auditor of the *excise*, and an auditor of bides, with their clerks, &c. A comptroller of cash, and another of accompts, with their clerks; a register; secretary; solicitor; receiver-general, with his clerks; clerk of tenantries; store-keeper, house-keeper; door-keepers; general accomptants, with their assistants; accomptant for bides, and two accomptants for the London brewery; clerk of the bills of exchange; examiners; clerk for supervisors duties; five general surveyors; general surveyors of distillery and brandy; examiners of the distillery; of the brewery, and of soap and candles; surveyors of glass, of coaches, and plate licences; inspector of spirituous liquors, licences, and coaches; inspectors general of coffee, tea, &c. and of brewery through England and Wales. Beside which, there are in England and Wales, exclusive of the bills of mortality, forty-nine collectors, who go their respective rounds once in six weeks: the province of a collector comprehends several districts, within each of which there is a supervisor, under the inspection of the collector; and each district is parcelled out into out-rides and foot-walks, within each of which there is an inferior officer, constituted under the hands and seals of the commissioners, or sub-commissioners, in their respective divisions, as necessity requires, and called gauger, or *excise-man*, under the inspection of the supervisor, who every six weeks draws out a diary of every day's business, with remarks, and transmits it to the chief officer. Every person, previous to his appointment to the office of gauger, must procure a certificate of his age, which must be between twenty-one and thirty; he must understand the four first rules of arithmetic, be of the communion of the church of England, and, if married, not have more than two children; he must nominate two able persons to be his sureties; and the certificate, containing these particulars, and written by himself, must be signed by the supervisor of the district where he lives, and accompanied with an affidavit, that he has used no bribes for obtaining this office. He is then ordered for instruction, under the care of an experienced officer, and to wait till a vacancy happens. Upon admission of officers of every kind relating to the excise, the oaths of allegiance and supremacy, and an oath of faithfulness in the execution of the particular office, must be taken, and the declaration against transubstantiation must be subscribed. Officers of *excise*, taking a bribe, are liable to a forfeiture of 200*l.* 25 Car. II. cap. 11. and a person liable to *excise* duties, offering them a bribe, &c. shall forfeit 500*l.* 12 Geo. cap. 30. Officers meddling in elections are subject to a penalty of 100*l.* and an incapacity of holding any office under the king. 5 W. cap. 20. The concealment of excisable goods is subject to a forfeiture of those goods, and treble value. 12 Geo. cap. 30. Any person obstructing an officer in the execution of his duty, shall forfeit 10*l.* 6 Geo. cap. 21. And an officer, either of the *excise* or customs, dealing in excisable liquors, shall forfeit 50*l.* and be incapable of any office in the revenue. 12 Geo. cap. 28.

EXCISION, in *Surgery*, the cutting out, or cutting off any part of the body.

EXCLAMATION, in *Rhetoric*, a figure, wherein, by raising the voice, and using an interjection either expreſly or underſtood, we teſtify an uncommon warmth, and paſſion of mind; and expreſs the magnitude of the thing, or the importance of the occaſion.

Such is, O heavens! O earth! &c. Such alſo is that of Cicero againſt Cataline: O times! O manners! this the ſenate knows, the conſul ſees—and yet he lives! Lives, ſaid I? nay, and comes into the ſenate!

In *Engliſh*, the interjections O! or oh! alas! or good God! are generally adjoined in an *exclamation*. In Latin they uſe *O! hei! væ! eheu! ah! vah! pro fidem! pro ſuperi! pro ſuperum atque hominum fidem!* Sometimes, however, the interjection is underſtood, as, Woe is me! *Miſerum me! miſerum me!*

EXCLUSION, the act whereby a perſon or thing is excluded, i. e. ſhut out, or ſet aſide. A crown imports an *excluſion* from the papacy: he appointed a ſtranger his heir, in *excluſion* of his own relations.

Great efforts were made towards the cloſe of the reign of king Charles II. to procure a *Bill of excluſion*, for ſetting aſide the duke of York, the king's brother, on account of his being a papiſt. See CROWN.

EXCLUSION, in *Mathematics*. The *method of excluſions* is a way of coming at the ſolution of problems (in numerical caſes) by previouſly ejecting, or *excluding* out of conſideration, ſuch numbers as are of no uſe in reſolving the queſtion; whereby, of conſequence, the proceſs may be regularly, and judiciouſly abbreviated.

EXCLUSIVE, is ſometimes uſed adjectively, for the force, or power, or *excluding* an, a patent carries with it an *excluſive* privilege.

Sometimes it is alſo uſed adverbially: as, he ſent him all the Gazettes, from N° 295, to N° 300, *excluſive*: i. e. all between thoſe two numbers, which themſelves were excepted.

EXCLUSIVE *propoſitions*, are thoſe wherein the predicate ſo agrees with its ſubject, as to agree with no other. See PROPOSITION. E. gr. Virtue alone makes nobility: nothing elſe renders a man truly noble.

EXCLUSORIUM, in *Medicine*, a name uſed, by ſome, for ſuch drugs, or compoſitions, as are capable of producing abortion.

EXCOECARIA, in *Botany*, a genus of the *dioecia triandria* claſs, bearing male and female flowers, each of which has a naked catkin, without calyx or corolla: the female flowers have three ſtyles, and a capſule with three cells, and a ſingle ſeed in each cell. There is one ſpecies.

EXCOMMUNICATION, an anathema, or eccleſiaſtical cenſure, and puniſhment; whereby a heretic is cut off from the ſociety of the faithful, or an obſtinate ſinner from the communion of the church, and the participation of the ſacraments.

This cenſure of *excommunication* was originally inſtituted for preſerving the purity of the church; but ambitious eccleſiaſtics converted it by degrees into an engine for promoting their own power, and inflicted it on the moſt frivolous occaſions.

The power of *excommunication* properly belongs to the biſhop; but he may delegate it to any grave prieſt, with the chancellor.

Every *excommunication* ſhould be preceded by three public admonitions, two days, at leaſt, diſtant from each other; but this is to be underſtood of *excommunications* impoſed by the eccleſiaſtical judge; for thoſe impoſed by the law are incurred to all intents and purpoſes the moment the action is committed.

Theſe latter are called *excommunications by the canon*, or *latæ ſententiæ*; and are ſo very numerous, that it would be difficult, even for the beſt canoniſts, to give an exact liſt of them; there are fifty in the Clementines; twenty in the bull *Cœna Domini*, &c. Wilkins's Mag. Conc. vol. iv. p. 660.

Reboulle, on the Concordat, reckons up ſixty penalties accruing upon *excommunication*.

Excommunication is founded on a natural right which all ſocieties have, of excluding out of their body ſuch as violate the laws thereof.

Excommunication is either *major* or *minor*, i. e. *greater* or *leſs*; the firſt, which is that underſtood when we ſay ſimply, *excommunication* ſeparates, or cuts off, the delinquent from all communion and fellowſhip with other Chriſtians; diſables him from defending his rights, bringing an action at law, be a witneſs, &c. The ſecond, or leſſer, only excludes from the communion of the Lord's ſupper.

The greater *excommunication*, called alſo *ab homine*, is when a prelate, or his deputy, *excommunicates* any man perſonally, and interdicts him all ſociety with the faithful, all uſe of ſacraments, &c.

In the ancient church, the ſentences of the greater *excommunication* were ſolemnly promulged four times in the year, with candles lighted, bells tolling, the cloſe, and other ſolemnities.

The leſſer *excommunication* is incurred *ipſo jure*, by having any communication with a perſon *excommunicated* in the greater *excommunication*. And this too imports a privation of communion, but not an interdiction from entering the church, nor having commerce with the faithful.

Anciently, the *excommunicated* were obliged to procure abſolution from their biſhop, and make ſatisfaction to the church, in forty days time; otherwiſe they were compelled to it by the ſecular judge, by a ſeizure of their chatls, impriſonment of their perſons, &c. See EXCOMMUNICATO *capiendo*. In France they were allowed a whole year.

By an edict of St. Louis, in the year 1228, vaſſals, tenants, &c. were diſpenſed, or freed from the oath of fidelity, homage, &c. they had taken to their lords, or ſuperiors, when excommunicate, till they had made their ſubmiſſion.

In *Spain*, to this day, a perſon who is not abſolved from his *excommunication* in a year's time, is deemed a heretic. There was a time, when the people were fully convinced, that the bodies of the *excommunicated* perſons, unleſs they were firſt abſolved, would not rot, but remain entire for ſeveral ages, a horrible ſpectacle to poſterity! as is atteſted by Matthew Paris, and other writers. And the Greeks are ſtill of the opinion; and affirm, they have many proofs thereof, as is ſhewn by Du-Cange, from the teſtimony of a vaſt number of authors.

By the laws, an *excommunicated* perſon was not to be buried, but the body flung into a pit, or covered with a heap of ſtones; which was called *tumulus corpi*. And by the rubric in the Book of Common Prayer, the burial office ſhall not be read for any that die *excommunicated*. See FUNERAL, &c.

In the ancient church, there were diverſe degrees of *excommunication*. In effect, *excommunication* did not always import an interdiction of the ſacraments; but frequently, a ſeparation, or kind of ſchiſm, between the ſeveral churches, or a ſuſpenſion of ſpiritual communication between the biſhops.

But afterwards, the occaſions of *excommunication* growing more frequent, they began to uſe it with leſs circumſpection and reſerveneſs.

In the ninth century, the eccleſiaſtics were continually making uſe of this ſpiritual weapon, to repel any violences, or affronts, offered them; and time and familiarity rendering offenders more and more obdurate, they proceeded, by degrees, to rigours unknown to antiquity; as the *excommunicating* of whole families, or provinces; prohibiting the exerciſe of all religion therein; and even accompanying the *excommunication* with horrible ceremonies, and direful imprecations.

In the tenth and eleventh centuries, the ſeverity againſt the *excommunicated* was carried to its higheſt pitch: nobody might come near them, not even their own wives, children, or ſervants: they forfeited all their natural and legal rights and privileges, and were excluded from all kinds of offices. Thus was an *excommunicated* king reduced to the condition of a private man. By thus ſtretching the power of the church to extravagance, they rendered it contemptible. Gregory VII. tempered it a little; exempting the wives and children of *excommunicated* perſons from incurring *excommunication*, by holding converſation with their huſbands and parents.

To render the *excommunicated* ſtill more odious, the prieſt was obliged to ſtop, and break off divine ſervice, if an *excommunicated* perſon entered the church; nothing of which averſion is any where diſcovered in the practice of the primitive church. At preſent we have but little of the terror or reſpect of our forefathers for *excommunication*; and it is even judged, and proclaimed, an abuſe whenever impertinently employed.

The form of *excommunication* in the Romiſh church, as related by Ferrer, is to take lighted torches, throw them on the ground with curſes and anathemas, and trample them under-foot to the ringing of the bells.

Auctoritate Dei Patris omnipotentis, & Filii, & Spiritus Sancti, & beatæ Dei genetricis Mariæ, omniumque ſanctorum, excommunicamus, *anathematizamus, & a limitibus ſanctæ matris eccleſiæ ſequeſtramus illos malefactores, N. ſententiamus quoque & damnamus; & niſi reſipuerint, & ad ſatisfactionem venerint, ſic extinguatur lucerna eorum ante vindictam in ſæcula ſæculorum. Fiat: Amen: Amen: Amen.* Ex Emendat. Will. Leg. Conqueſt.

We have now none of this folly; the ſentence is gravely read, and the perſon remains *excommunicated* without farther ceremony.

See the form of *excommunication* of the Engliſh church in Concilia M. Brit. & Hib. vol. iv. p. 665, &c.

Petrus Bleſenſis aſſures us, that in England it was anciently

only the practice only to *excommunicate* such as had killed an ecclesiastic; whereas they were put to death who had killed a layman. But the reason was, they held *excommunication* a greater punishment than death.

The causes with us are contempt of the bishop's court, heresy, neglect of coming to church, and of receiving the sacrament, incontinency, adultery, simony, &c.

We have instances of bishops, who have pronounced formal *excommunications* against caterpillars, and other insects, after a formal juridical process against them, wherein those animals were allowed an advocate, and proctor, to defend their cause. See Ecnocius.

Favyn relates divers instances of such *excommunications* against rats, mice, and other animals, for infesting a country. See the form of these *excommunications* in that author, Traité de l'Abus.

In the ancient church there were two different kinds of *excommunication* in use: the one called *minor*, whereby persons convicted of a crime by their own confession, were removed from communion; the other, called *major*, was fulminated against rebels, who persisted obstinately in their errors and impieties.

The power of *excommunicating* was lodged in the whole church in general; that is, the bishops and priests had the administration thereof, by and with the consent of the people, which was practised even in St. Cyprian's time. But afterwards they ceased to consult the people about the matter; the bishop and clergy arrogated the whole power to themselves. Recourse, however, might still be had to a synod of the province, to judge of the validity of an *excommunication*.

Excommunication, was also practised among the Jews, who used to expel from their synagogue such as had committed any grievous crime. See the Gospel according to St. John, ix. 22. xii. 42. xvi. 2. And Joseph. Antiq. Jud. lib. ix. cap. 12. and lib. xvi. cap. 2.

The Elect, when *excommunicated*, durst not so much as receive food at any person's hand, for fear of violating their oath; but contented themselves to live on herbs; insomuch that they frequently perished, and died for want. See Joseph. de Bell. lib. ii. cap. 12.

Godwyn, in his Moses and Aaron, distinguishes three degrees, or kinds of *excommunication* among the Jews. The first he finds intimated in St. John ix. 22. The second in St. Paul, Epist. 1 Cor. v. 5. And the third, in the 1st Ep. to Corinth. xvi. 22. See Nidui.

The rule of the Benedictines gives the name *excommunication* to the being excluded from the oratory, and the common table of the house, in one sense of court called *discommuning*. This was the punishment of such monks as came too late.

Excommunication, or being secluded, or cut off from a participation in the mysteries of religion, was also in use under paganism.

Such as were thus *excommunicated* were forbidden to assist or attend at the sacrifices, or to enter within the temples; and were afterwards delivered out to the demons and furies of hell, with certain imprecations; which was called among the Romans, *dirus devovere*. See Execration.

The Druids, among the ancient Britons and Gauls, likewise made use of *excommunication* against rebels; and interdicted the communion of their mysteries to such as refused to acquiesce in their decisions. See Druids.

That this is the true origin of the extensive and horrid influence of the European and papal *excommunication*, will appear evident by the following passage of Cæsar, De Bello Gallico, lib. vi. cap. 13. *Si quis aut privatus aut publicus Druidum decreto non stetit, sacrificiis interdicunt. Hoc pœna apud eos est gravissima. Quibus ita est interdictum, hi numero impiorum & sceleratorum habentur, iis omnes decedunt, aditum eorum sermonemque defugiunt, ne quid ex contagione incommodi accipiant; neque iis petentibus jus redditur, neque honos ullus communicatur.*

Excommunicato *Capiendo*, or *Significavit*, a writ directed to the sheriff, for the apprehension of one who stands obstinately *excommunicated* the space of forty days. Such a one, not seeking absolution, hath, or may have, his contempt certified into the chancery; whence this writ issues for laying him up, without bail or mainprize, until he conform himself.

Excommunicato *Deliberando*, is a writ directed to the under sheriff for the delivery of an *excommunicated* person out of prison; upon certificate of the ordinary of his conformity to the ecclesiastical jurisdiction.

Excommunicato *Recipiendo*, is a writ whereby persons *excommunicated*, being for their obstinacy committed to prison, and unlawfully delivered from thence before they have given security to obey the authority of the church, are commanded to be sought for, and laid up again.

EXCORIATION, in *Medicine* and *Surgery*, the galling or rubbing off of the cuticle; especially of the parts between the thighs, or about the anus.

In adults, it is occasioned by riding, much walking, or other vehement exercise, and may be cured by vulnerary applications.

In children, there is often an *excoriation* of the parts near the pudenda, chiefly of the groin and scrotum, but likewise in the wrinkles of the neck, under the arms, and in other places, proceeding from the acrimony of the urine and sweat, and occasioning itching pains, crying, watching, and restlessness.

To remedy this, the parts affected may be washed often with warm water, and sprinkled with drying powders, as chalk, hartshorn, but especially tutty, lapis calaminaris, and ceruse; which may be tied loosely in a rag, and the powder shook out on the disordered place. If the parts tend to a real ulceration, it will be proper to add a little sugar of lead to the powder, or to anoint the place with unguent. alb. camphor. Likewise a little vitriol dissolved in spring water, and daubed upon the part, will dry and heal it very powerfully.

We also say, an *excoriation* in the throat, &c. when the membrane that covers it, or lines it, is torn by the acrimony of a humour, a medicine, or the like; which is ordinarily the case in what we call a *sore throat*.

EXCORIATION, the act of stripping off the cortex, or bark, from any thing; called also DECORTICATION.

EXCREMENT, that which is evacuated, or *excreted*, out of the body of an animal, after digestion; being what in other respects is superfluous and prejudicial thereto. See Excretion.

Excrements is all that matter taken in by way of food, which cannot be assimilated; and which, of consequence, not growing or adhering to the body, wanders about through the lacteal, and more potent parts thereof, till it be ejected.

The urine and faces, or fecal matter, are the *great excrements*, expelled from the bladder, and the intestines, by stool, &c.

The matter of insensible perspiration is also an *excrement*, and a more considerable one than either of the others.

Among *excrements* are likewise ordinarily ranked diverse humours and matters, separated from the blood by the several strainers, or emunctories of the body, though far from being useless, but having several valuable purposes of the economy. Such are the cerumen, or ear-wax; the mucus of the nose; lachrymæ, or tears; saliva, bile, lympha, menses, lochia, &c. See Cerumen, Mucus, Tears, Saliva, Bile, Menses, &c.

Unless the excretions are regular, health cannot be maintained; and therefore if they are too plentiful, defective, or suppressed, they will occasion various disorders. Hence if a person be costive, it is generally the forerunner of some disease. As a man generally takes more aliment than is necessary to generate blood and serum, and the common excretions are not sufficient to carry off superfluous humours, extraordinary ones sometimes happen at stated times; as the piles, hæmorrhages, &c.

Excrement is also attributed, by way of analogy to plants. Thus gums, dracha juices, balms, &c. issuing spontaneously from their respective trees, are sometimes called *excrements*.

EXCRESCENCE, in *Surgery*, denotes superfluous, or luxurious flesh, or other matter, growing on certain parts of the bodies of animals, contrary to, or beyond the ordinary structure, and disposition of nature.

The word is formed of the Latin *ex*, and *crescit*, *I grow*; q. d. something that grows from, or out of another.

Such are warts, warts, nevises, polypuses, &c.

Natural, or customary *excrescences*, as that of bones, &c. are called by physicians *apophyses*.

EXCRETION, formed of *excernere*, *to separate*, in *Medicine*, the act of expelling or ejecting out of the body some humour that is useless or even hurtful thereto.

Most critics are effected by *excretions*, as fluxes of blood and urine, sweat, vomitings, loosenesses, &c.

EXCRETORY, in *Anatomy*, is applied to certain little ducts, or vessels, in the fabric of the glands.

Excretory ducts are the tubes through which the humours, separated in the several glands, are emitted, or discharged out of the gland, into some immediate receptacle, or emunctory.

A capillary artery, to which a capillary vein is joined, with an *excretory* duct, compacted, or bound together, make up the body of the glands, the organs of secretion.

The *excretory* ducts spring from the extremities of the arteries and veins, and carry off a liquor separated from the blood. Drake.

The lymphatic glands have either lymphæ ducts for their *excretory ducts*, or lacteal vessels, as in the mesentery. Idem.

EXCURSION, in *Astronomy*. See Elongation.

Excursion, *circles of*. See Circles.

EXCUSATI, in *Church History*, a term used to denote slaves, who flying to any church for sanctuary, were excused

cused and pardoned by their masters; but these were obliged to take an oath to that purpose before they could have them again; and, if they broke the oath, they were punished and fined as perfons guilty of perjury.

EXCUTIA *ventriculi*, the *stomach-brush*, a name given, by modern surgeons, to an instrument made of soft bristles formed into a bundle, and fixed upon a flexible brass wire, for cleaning the throat, or even the stomach.

The *stomach brush* is composed of soft hair, fastened together into a bundle by a twisted brass or steel wire, and the handle or stem of it is invested with silk. This has been greatly recommended, by some, to remove foreign bodies out of the fauces and œsophagus, and to scour the stomach. The method of using it is this.

The patient is first to drink a small draught of warm water, then the brush is to be received into the œsophagus, and gently protruded down into the stomach, by twisting round and round its handle, and, when in the stomach, it is to be drawn up and down many times, like the sucker in a syringe, and at length wholly extracted. The advantages said to arise from this are very great, such as the prolonging life to a great age, and the like; but few people have been willing to try the effects of so disagreeable and troublesome an operation. Wedelius and Teichmeir have written expressly treatises on this instrument; and one of them has attempted to prove it no new contrivance, but a thing very early known, described, and used in physic. Heister's Surgery, part ii. p. 2.

EXEAT, in *Church Difcipline*, a Latin term, used for a permission, which a bishop grants a priest to go out of his diocese; or an abbot, to a religious, to go out of his monastery.

The word is also used in several great schools for leave given a scholar, or student, to go out. His master has given him an *exeat*.

EXECRATION, *Execratio*, among the *Jewiſh*, a kind of punishment, consisting of direful curses and marks of infamy. Levy relates an instance of it, which was used against Philip, king of Macedon, by the Athenians. A general assembly of the *people* being called, they made a decree, that all the statues and images of the king, and of all his ancestors, both of the male and female sex, should be demolished, and their very names razed; that all the festivals, sacred rites, priests, and whatever else had been instituted in honour of him, should be profaned; that the very places, where these had been any monument or inscription to his honour, should be detestable, and that nothing should be set up, or dedicated in them, which could be done in clean places; and, lastly, that the public priests, as often as they prayed for the Athenian people, allies, armies, and fleets, should as many times detest and execrate Philip, his children, kingdom, land and sea forces, and the whole race and name of the Macedonians.

Cornelius Nepos, in his Life of Alcibiades, calls it *devotio*.

At the taking and demolishing of a city, it was frequent to pronounce direful curses and *execrations* upon any person who should endeavour to rebuild it; which some imagine was the reason that Troy could never be raised out of its ashes, though several persons attempted it, being devoted to eternal and irreparable ruin by Agamemnon. This seems to have been a very ancient custom, and derived from the eastern nations; for we find Joshua, at the destruction of Jericho, to have fixed an imprecation upon the person who should rebuild it, which was thought to be accomplished in Hiel the Bethelite many ages after. Potter, Archæol. tom. ii. p. 57.

EXECUTED *fine*. See FINE.

EXECUTION, the act of executing, i. e. of accomplishing, finishing, or achieving any thing, to be done.

We say, the *execution* of a testament; of a law; of a treaty; of a building, or the like.

EXECUTION is particularly used, in the French *Muſic*, for the manner of singing, or of the performance of a song. As to the manner of singing, called in France *execution*, no nation may, with any probability, dispute it with the French. If the French, by their commerce with the Italians, have gained a better composition, the Italians have made their advantage of the French, in learning of them a more polite, moving, and exquisite *execution*. St. Evremont.

EXECUTION, in *Common Law*, signifies the last performance of an act, as of a writ, a judgment, or the like.

EXECUTION *of a judgment*, is the obtaining of the poſſeſſion of any thing recovered by judgment of law.

There are two sorts of *executions*; one *final*, another *with a quoniam*, as only tending to an end.

EXECUTION, *final*, is that which maketh money of the defendant's goods, or extendeth his lands, and delivers them to the plaintiff: for this the party accepts in satisfaction; and this is the end of the *suit*, and all that the king's writ commands to be done.

EXECUTION *with a quoniam*, is that which only extends to an end; as is the case of a *capias ad ſatisfaciendum*, &c. This is not final; but the body of the party is to be taken, to the intent and purpose to satisfy the plaintiff; and his imprisonment is not absolute, but till he doth satisfy, fo that the body is but a pledge for the debt.

Executions are either in perſonal, real, or mixed actions. In a perſonal action, the *execution* may be made three ways, viz. by the writ of CAPIAS *ad ſatisfaciendum*, against the body of the defendant; FIERI *facias*, against his goods; or ELEGIT, against his lands. In a real and mixed action, the *execution* is by writ of HABERE *facias ſeiſinam*, and *habere facias poſſeſſionem*.

EXECUTION, *tenant by*. See TENANT.

EXECUTION, *military*, is the pillage or plundering of a country by the enemies army.

EXECUTION, *military*, also denotes every kind of punishment inflicted on an army by sentence of a court martial. This is of various kinds; as tying up to three halberts, and receiving a number of lashes with a whip, compoſed of nine cord-lashes, and each lash of nine knots, from the drummer; or running the gantlope through the parade at guard-mounting, drawn up in two lines for that purpoſe. On this occasion the provoſt marches through with twigs or switches, and every soldier takes as many as there are criminals to be punished; the criminal then marches through the two lines, and each soldier giving him a hard stroke, the major riding up and down to see that the men lay on properly. When a soldier is to be punished with death, a detachment of about two hundred men from the regiment to which he belongs forms the parade, and a file of grenadiers shoots the prisoner to death.

EXECUTION *of criminals* muſt be according to judgment; and the king cannot alter the judgment from hanging to beheading, because no *execution* can be warranted, unleſs it be pertinant to the judgment. 3 Inſt. 52. 211. H. P. C. 252. But there are ancient precedents wherein men condemned to be hanged for felony, have been beheaded by force of a ſpecial warrant from the king. Dract. 104. Staundf. 178. And the king may pardon part of the *execution* in judgment for treaſon, *viz.* all but beheading. The court may command *execution* to be done without any writ; though ſometimes *execution* is commanded by writ. 2 Hawk. P. C. 462. Judgment belongs to the judge; but the *execution* muſt be done by the sheriff, &c. and an *execution* cannot be lawfully made by any but the proper officer; who may do it by the precept of the judge under his ſeal; and if the sheriff, or other officer, alters the *execution*, or any other executes the offender, or if he is killed without the authority of law, it is felony. 2 Hawk. ib.

In caſe a man, condemned to die, come to life after he is hanged, as the judgment is not executed till he is dead, he ought to be hung up again. Finch, 389. The body of a traitor, or felon, is forfeited to the king by the *execution*.

EXECUTIONE *faciendo*, a writ commanding execution of a judgment.

EXECUTIONE *facienda in withernamium*, lies for taking the cattle of one who had formerly conveyed out of the county the cattle of another.

EXECUTIONE *judicii*, in *Law*, a writ directed to the judge of an inferior court, to do *execution* upon a judgment therein, or to return ſome reaſonable cauſe wherefore he delays the *execution*. F. N. B. 20.

If *execution* be not done on the firſt writ, an *alias* ſhall iſſue, and a *pluries*, with this clauſe, *vel cauſam nobis ſignifiet quare*, &c. And if, upon this writ, *execution* be not done, or ſome reaſonable cauſe returned why it is delayed, the party ſhall have an attachment againſt him who ought to have done the *execution*, returnable in B. R. or C. B. New Nat. Br. 43.

EXECUTIVE *power, ſupreme*, is by the conſtitution of theſe kingdoms lodged in a ſingle perſon, the king or queen, for the time being. See CROWN.

EXECUTOR, a perſon nominated by a teſtator, to take care to ſee his will and teſtament *executed* or performed, and his effects diſpoſed of according to the tenor of the will.

The teſtaments made in Latin in the fourteenth century, call *executors*, *promiſores teſtamentarii*.

All perſons are capable of being *executors*, that are capable of making wills, and others beſides; as feme-coverts and infants, and infants unborn; but no infant can act, as *executor*, till he is ſeventeen years of age. This appointment of an *executor*, either by expreſs words, or by ſuch as ſtrongly imply the ſame, is eſſential to the making of a will; but if the teſtator names no *executors*, or names incapable perſons, or if the *executors* that are named refuſe to act, the ordinary muſt grant letters of adminiſtration. See ADMINISTRATOR.

A perſon appointed to be *executor* is not compellable to

execute

execute the will; he may refuse the *charge*, before he has administered as *executor*, or performed such acts, as paying debts due by the testator, or receiving debts due to him, or giving acquittances for the same; but if he meddles with the goods of the testator, as *executor*, his subsequent refusal is void, and he shall be charged as *executor*. A person to whom a legacy is left may be compelled either to stand the executorship, or to resign his legacy. The *refusal* of executorship must be entered and recorded in court. If several *executors* are named in a will, and some of them refuse, and others prove the will, they who refuse may afterwards administer and act; and they shall be joined in all suits, where the *co-executors* are plaintiffs; but not where they are defendants, because the plaintiff in the action is not bound by law to take notice of any besides those who have proved the will.

As to the office or duty of an *executor*, it is to be observed that he may do many things before he proves the will, which an administrator cannot do; because the former derives his power from the will, and not from the probate, or appointment of the ordinary, as the latter does. He may maintain actions of trespass, replevin, or detinue; release an action, assent to a legacy, be sued, alien, or otherwise intermeddle with the goods of the testator; by administering, the *executor* is entitled to receive all debts due to the testator, and all payments made to him are good, though he should die, and never prove the will; but he cannot maintain a suit or action of debt, or the like, before he has proved the will. The ordinary, &c. may cite the *executor*, either to prove the will, or refuse the office; and he may sequester the goods of the deceased, till the *executor* has proved it; and if he does not appear on the process, the ordinary may excommunicate him. On the other hand, the ordinary is compellable by mandamus to proceed to PROBATE, when the will is not controverted. The *executor* must bury the deceased in a manner suitable to the estate he leaves behind him; necessary funeral expences are allowed, previous to all other debts and charges; but if he be extravagant, he is chargeable with devastation, or waste of the substance of the deceased, which shall be only prejudicial to himself, and not to the creditors or legatees of the deceased. He is then to make an inventory of all the goods and chattels, whether in possession or action of the deceased, which he is to deliver in to the ordinary upon oath, if lawfully required, at the time of probate. He is then to collect all the goods and chattels so inventoried; for which purpose the law confers on him ample powers, as the representative of the deceased; and having the same property in his goods as the principal had when living, and the same remedies to recover them; and if there be two or more *executors*, a sale or release by one of them shall be good against all the rest. The *executor* must in the next place pay the debts of the deceased, in the order of their priority. See DEBTS, and DEBTS *executor*.

If no suit is commenced against him, the *executor* may pay any one creditor in equal degree his whole debt though he has nothing left for the rest; for, without a suit commenced, the *executor* has no legal notice of the debt. After the debts, the *executor* is to pay the legacies, which he is to pay as far as his assets will extend; but he may not give himself the preference herein, as in the case of debts. In case of a deficiency of assets, all the *general* legacies must abate proportionably, in order to pay the debts; but a *specific* legacy, as of a piece of plate, house, &c. is not to abate at all, unless there be not sufficient without it. If the legatees have been paid their legacies, and debts come in more than enough to exhaust the residuum, they are afterward bound to refund a ratable part. See LEGACY, and DONATION *causa mortis*.

When all the debts and legacies are discharged, the surplus or residuum must be paid to the *residuary* LEGATEE, if any be appointed by the will; if there be none, it was formerly understood to belong to the *executor*; but it seems to be now the general opinion, that, if there be an express legacy given to an *executor*, and no devise of the surplus, such surplus shall not go to the *executor*, but be disposed to the next of kin, according to the statute of distributions; the *executor* standing on the same footing as an ADMINISTRATOR. See INTESTATE.

Where no express legacy is given to the *executor*, the surplus shall go to the *executor*, if not otherwise disposed of by WILL. When there are several *executors*, and some of them are dead, the legacy must vest in the surviving *executors*, and not the *executors* or administrators of those that are dead. And if all the *executors* are dead, he must sue the *executors* or administrators of those that died last, and not those of the rest.

By the French law, an *executor* should be seised of all the moveables of the deceased during one year; at the end whereof he is to account for them. To the validity of a testament, it is not necessary there be an *executor* nominated therein.

EXECUTOR *de son tort*, or of his own wrong, is he who takes on him the office of an *executor* by intrusion, not being constituted thereto by the testator, or deceased, nor authorized by the ordinary to administer.

If an *executor* in his own wrong takes upon himself the office of an *executor* without lawful authority, he is chargeable to the rightful *executor*, and to all the creditors of the testator, and likewise to the legatees, so far as the goods amounted to, which he wrongfully possessed; and such an *executor* is made by any act of acquisition, transferring, or disposing himself of any of the effects or goods of the deceased, but not by acts of necessity, piety, or charity. 2 Nelson 895, 903. Such an *executor* cannot bring an action in right of the deceased; neither can he retain for his own debt or legacy. In case of his death, his *executors* or administrators are liable to the suit of the lawful *executor*, creditors, and legatees, by 30 Car. II. cap. 7.

EXECUTOR, *Dutch*. See DEVISEE.

EXECUTORY, that which has, or carries with it a sufficient authority for being executed.

A contract is only *executory*, when it is in form, and sealed: the great seal of England is *executory* throughout the whole island.

EXECUTORY *devise*, is where a future interest is devised, that vests not in the death of the testator, but depends on some contingency which must happen before it can vest. Thus, if a particular estate is limited, and the inheritance passed out of the donor, this is a CONTINGENT *remainder*; but where the fee by a devise is vested in any person, and to be vested in another upon contingency, this is an *executory* devise. And in all cases of *executory* devises, the estates descend until the contingencies happen.

EXECUTORY *estate* is an estate in fee, created by deed or WILL, which is to be afterwards executed by entry, livery, writ, or the like; and others executed are those which pass presently to the person to whom they are conveyed, without any subsequent act.

EXECUTORY *writ*. See WRIT.

EXEDENS *hæres*. See HEREDES.

EXEDRÆ, Εξεδραι, among the *Ancients*, were places wherein the philosophers, sophists, rhetors, &c. used to hold their conferences and disputes.

M. Perrault is of opinion, the *exedræ* were a sort of little academies, where the men of learning met together. See ACADEMY.

Budæus rather thinks, that what the ancients called *exedræ*, might answer to what we call *chapters* in the cloisters of monks, or collegiate churches.

EXEGESIS, Εξηγησις, a term sometimes used by the learned, to signify *explication*.

Several interpreters of the Bible are of opinion, that in the passages of Scripture, where we meet with Abba Pater, two words, the first Syriac, and the second Greek or Latin, but both signifying the same thing; the second is only an *exegesis*, or explanation of the first.

EXEGESIS is also used for an entire discourse by way of explication, or comment, on any thing.

EXEGESIS *numerosa*, or *linealis*, signifies the numeral, or lineal solution, or extraction of roots, out of affected equations, first invented by Vieta. Ozanam calls it *la rhetorique*. See EXTRACTION *of roots*.

EXEGETES, formed of εξηγεομαι, *I explain*, among the Athenians, persons learned in the laws whom the judges used to consult in capital causes.

EXEGETICA, in *Algebra*, the art of finding, either in numbers or lines, the roots of the equation of a problem according as the problem is either numerical, or geometrical. See ROOT, and EQUATION.

EXEMPLAR, a MODEL, or original, to be imitated, or copied.

EXEMPLAR also denotes the idea, or image, conceived, or formed in the mind of the artist, whereby he conducts his work. Such is the idea of Cæsar, which a painter has in his mind when he goes to make a picture of Cæsar.

The *exemplar* is ordinarily numbered among the causes. See CAUSE.

EXEMPLIFICATION *of letters patent*, denotes an exemplar, or copy of letters patent, made from the inrolment thereof, and sealed with the great seal of England.

Such *exemplifications* are as effectual to be shewed, or pleaded, as the letters patent themselves.

EXEMPLIFICATION, in *Law*, is a writ granted for the exemplification of an original record. Reg. Orig. 290.

EXEMPTION, a privilege or dispensation, whereby a person is excepted out of some general rule.

Exemption is particularly applied to churches, chapels, and monasteries, which have a privilege given them by the pope, or princes, whereby they are exempted from the jurisdiction of the bishop, or ordinary.

The council of Constance revoked all *exemptions*, to restore to the general law weakened and diminished by a relaxation of several ages, its ancient force and vigour, and make it every where obtain in all its latitude.

The council of Trent prohibited and declared them null for the future: confirming only such as were well founded on legal concessions from the holy see.

EXEMPTION, in *Law*, denotes a privilege to be free from service or appearance; thus, knights, clergymen, &c. are exempted from appearing at the county courts by statute, and peers from serving on inquests. Persons seventy years of age, apothecaries, &c. are also exempted by law from serving on juries, and justices of peace, attorneys, &c. from parish offices.

EXERCISE, a repetition of any operation for the strengthening, or retaining of a habit.

Thus we use *exercise* of the body for acquiring, or maintaining health; as it conduces both to the expulsion of the excrements, and preserving the tone and spring of the fibres.

People who live a sedentary life, and do not use *exercise*, are liable to an universal relaxation of the solids, which brings on other disorders, as nervous obstructions, weak nerves, and defect of perspiration. Games of hazard are to be discountenanced, and those of *exercise* to be promoted.

Exercise and diet make one of the physicians NON-NATURALS. See GYMNASTICS.

Labour, or *exercise*, Dr. Cheyne observes, is indispensibly necessary to preserve the body any time in due plight. Let meats be purest, savoury, well-assisted, both in quantity and quality; let evacuative excretions be used to relieve the stomach, or any inconvenience be proposed to prevent the generation, still our bodies are to waste, and the natural œconomy is to continued, that, without due labour and *exercise*, the juices will thicken, the solids will fatten, the nerves will relax; and, from these disorders, chronical diseases, and a crazy old age, must ensue. Essay on Health, p. 90.

Of all the *exercises* that are, or may be, used for health, as walking, riding on horse-back, or in a coach, fencing, dancing, bowling, digging, pumping, rinsing, &c. walking is the most natural, and would be the most useful, if it did not spend too much of the spirits of the weakly. But riding is certainly the most manly, the most healthy, and is less laborious and expensive of spirits than any.

It is generally said that *riding* is a more healthful *exercise* than walking; which appears to be an allusion a little too general; for walking is much more effectual in promoting an increase of muscular strength, and in imparting to the fibres a due elasticity, than riding. But where any of the aforesaid much obstructed, and a patient is too weak to support sufficient walking *exercise*, in such case riding may be more beneficial. Upon the whole it may be said, that walking is best for the preservation of health, but riding for the relief of chronical distempers; but in those which are acute, neither of them is advisable.

Those organs of the body that are most used, always become strongest; so that we may strengthen any weak organ by *exercise*. Thus, the legs, thighs, and feet of chairmen; the arms and hands of watermen; the backs and shoulders of porters, grow thick, strong, and brawny, by their employ. It is certain, also, that speaking strong and loud will strengthen the voice, and give force to the lungs. To the asthmatic, therefore, and those of weak lungs, I would recommend, says Dr. Cheyne, talking much, and loud; walking up easy ascents, &c. to those of weak nerves, and digestion, riding on horseback; to those troubled with the stone, riding over rough causeways in a coach; to those troubled with rheumatic pains, playing at billiards, cricket, or tennis; to those of weak arms, or hands, playing at tennis, or foot-ball: to those of weak backs, or breasts, ringing a bell, or working at the pump. Walking through tough roads, even to lassitude, will belt recover the use of the limbs to the gouty; though riding will belt prevent the disease; but the studious, the contemplative, the sedentary, and those of weak nerves, must make *exercise* a part of their religion. A condition necessary to render *exercise* as beneficial as may be, is, that it be used on an empty stomach. Under the head of *exercise*, cold bathing, and the flesh-brush come also to be recommended. Id. ibid. p. 103, 104, &c.

Proper exercise conduces much to the health of soldiers in camp.

The *exercise* of a soldier may be considered under three heads; the first relating to his duty, the second to his living more commodiously, and the third to his diversions.

The first, consisting chiefly in the *exercise* of his arms, will be no less the means of preserving health, than of making him expert in his duty; and frequent returns of this early, and before the sun grows hot, will be made more advantageous than repeating it seldom, and staying too long out at a time; for a camp allowing little convenience for refreshment, all unnecessary fatigue is to be avoided.

As to the second article, cutting boughs for shading the tents, making trenches round them for carrying off the water, airing the straw, cleaning their cloaths and accoutrements, and shifting in the business of the mess, ought to be no disagreeable *exercise* to the men for some part of the day.

Lastly, as to diversions, the men must be encouraged to them, either by the example of their officers, or by small premiums to those who shall excel in any kind of sports, as shall be judged most conducive to health; but herein great caution is necessary, not to allow them to fatigue themselves too much, especially in hot weather, or sickly times; and above all, that their cloaths be kept dry, wet cloaths being the most frequent cause of camp diseases.

EXERCISE, in the *Art of War*, denotes the ranging of a body of soldiers in form of battle, and making them practise the several motions and military evolutions, with the diverse management of their arms, &c. to make, or keep them expert therein against occasion.

This is what Vegetius, and other Latin writers, call *meditatio*.

EXERCISE, *infantry*, or *manual*, consists in the observance of certain words of command appointed for this purpose. When a regiment is drawn up, or paraded for *exercise*, the men are placed three deep, either by companies, or divided into platoons, with the grenadiers on the right. When soldiers are drawn up for *exercise*, the ranks and files should be exactly even, and each soldier should be instructed to carry his arms with ease, keep his firelock steady, and rest upon his shoulder, with the right hand hanging down, and the whole body without constraint. The distances between the files must be equal, and the ranks eight inches distant from each other. Every motion should be performed with life, and the greatest exactness observed in all firings, wheelings, and marching; and therefore a regiment should never be under arms longer than two hours.

The following is an abstract of the words of command in the manual *exercise*, with their explanations. 1. *Poise your firelock*, i. e. seize the firelock with your right hand, and turn the lock outwards, keeping the firelock perpendicular; then bring up the firelock with a quick motion from the shoulder, and seize it with the left hand, just above the lock, so that the fingers may lie upon the flock, with the elbows down, and the thumb upon the flock; the firelock must not be held too far from the body, and the left hand must be of an equal height with the eyes. 2. *Cock your firelock*; i. e. turn the barrel opposite to your face, and place your thumb upon the cock, raising your elbow square at this motion: then cock your firelock, by drawing your elbow down, placing your right thumb on the breech-pin, and the fingers under the guard. 3. *Prime*; i. e. step back about six inches to the rear with the right foot, bringing the left toe to the front; at the same time the butt-end of the firelock must be brought to an equal height with the shoulder, placing the left hand on the swell, and the fore-finger of the right hand before the trigger, sinking the muzzle a little. 4. *Fire*; i. e. pull the trigger briskly, and immediately after bringing up the right foot to the inside of the left, come to the priming position, with the look opposite to the right breast, the muzzle to the height of the hat, keeping it firm and steady; and at the same time seize the cock with the fore-finger and thumb of the right hand, the back of the hand being turned up. 5. *Half-cock your firelock*; i. e. half-bend the cock briskly with a draw-back of the right elbow, bringing it close to the butt of the firelock. 6. *Handle your cartridge*; i. e. bring your right hand with a short round to your pouch, flapping it hard; seize the cartridge, and bring it with a quick motion to your mouth; bite the top well off, and bring the hand as low as the chin, with the elbow down. 7. *Prime*; i. e. shake the powder into the pan, placing the three last fingers behind the rammer, with the elbow up. 8. *Shut your pan*; i. e. shut your pan briskly, drawing your right arm at this motion towards your body, holding the cartridge fast in your hand, as before; then turn the piece nimbly round to the loading position, with the lock to the front, and the muzzle to the height of the chin, bringing the right hand behind the muzzle, with both feet kept fast in this motion. 9. *Charge with cartridge*; i. e. force up your hand, and put the cartridge

into the muzzle; shaking the powder into the barrel; place your ram-rod, clinch with a quick and strong motion, upon the rammer. 10. *Draw your rammer*; i. e. draw the rammer with a quick motion half out, seizing it at the muzzle back-handed; *draw it quite out, turn it*, and enter it into the muzzle. 11. *Ram down your charge*; i. e. ram the cartridge well down in the barrel, instantly recovering and seizing the rammer back-handed at the centre, turning it, and entering it as far as the lower pipe, placing at the same time the edge of the hand on the butt-end of the rammer, with fingers extended. 12. *Return your rammer*; i. e. return the rammer, bringing up the piece with the left hand to the shoulder, seizing it with the right hand under the cock, keeping the left hand fall at the same time, turning the body square to the front. 13. *Shoulder your firelock*; i. e. quit the left hand, and place it strong upon the butt; quit the right hand, and throw it down the right side. 14. *Rest your firelock*; i. e. seize the firelock with the right hand, turning the lock outwards; raise the firelock from the shoulder, and place your left hand with a quick motion above the lock, holding the piece right up and down in both hands before you, and your left hand even with your eyes; step briskly back with your right foot, placing it a hand's-breadth distance from your left heel, and the same time bring down your firelock as quick as possible to the reft, sinking it as far down beside your left hand as your right hand will permit without constraint; your left hand being at the feather-spring, and your right, with fingers extended, held under the guard, taking care to draw it the muzzle well towards your body, and to dress in a line with the butt end. 15 *Order your firelock*; i. e. place your firelock nimbly with your left hand against your right shoulder; quit the firelock with your right hand, sinking it at the same time with your left; seize at the muzzle, which must be of an equal height from the chin, and hold it close against your right side; lift up your right foot, and place it by your left; at the same time throw back your left hand by your left side, and with your right bring down the butt-end thrice upon the ground, placing it even with the toe of your right foot; the thumb of your right hand lying along the barrel, and the muzzle kept at a little distance from your body. 16. *Ground your firelock*; i.e. half face to the right upon your heels, and at the same time turn the firelock, so that the lock may point to the rear, and the flat of the butt-end be against the infide of your foot; at the same time flipping the right foot behind the butt of the firelock, the right toe pointing to the right, and the left to the front: ftep directly forward with the left foot, about as far as the fwell of the firelock, and lay it upon the ground; your left hand hanging down by your left leg, and your right kept full, with the back-end against it; raife yourfelf up again nimbly, bringing back your left foot to its former pofition, keeping your body facing to the right; face again to the left upon your heels, and come to your proper front, letting your hands hang down without motion. 17. *Take up your firelock*; i. e. face to the right upon both heels; fink your body down, and come up to the pofition defcribed in the fecond motion of grounding; raife yourfelf and firelock, bringing it clofe to your right fide; come to your proper front, feizing your firelock at the muzzle, as in explanation 15. 18. *Reft your firelock*; i.e. bring your right hand as far as the fwell; raife the firelock high up in a perpendicular line from the ground with your right hand, and feize it with your left above the firing, the cock being at the height of the waift-belt; ftep back with your right foot, placing it behind your left heel, and come to the reft. 19. *Shoulder your firelock*; i. e. lift up your right foot, and place it by your left; bring the firelock at the fame time to your left fhoulder, and feize the butt-end with the left hand, keeping it in the fame pofition as above defcribed; throw your right hand briskly back. 20. *Secure your firelock*; i. e. bring the right hand briskly up, and place it under the cock, keeping the firelock fteady in the fame pofition; quit the butt with the left-hand, and feize the firelock with it at the fwell, bringing the elbow clofe down upon the lock; the right hand being kept faft in this motion, and the piece ftill upright: quit the right hand, and bring it down your right fide, bringing the firelock nimbly down to the *fecure*; the left hand in a line with the waift-belt. 21. *Shoulder your firelock*; i. e. bring the firelock up to a perpendicular line, feizing it with the right hand under the cock; quit the left hand, and place it ftrong upon the butt; quit the right hand, and bring it fmartly down the right fide. 22. *Fix your bayonet*; i. e. firft and fecond motions, as in the two firft of the *fecure*; quit the right hand, and bring the firelock fmartly down to the left fide with the left hand, as far as it will admit without conftraint, feizing the bayonet at the fame time with the right hand, and fixing it, placing that hand juft below the brafs, with the piece kept clofe to the hollow of the fhoulder. 23 *Shoulder your firelock*; i. e. quit the right hand, and bring up the firelock with the left; feize it again under the cock with your right, as in the fecond motion of the *fecure*; quit the left hand, and place it ftrong upon the butt; quit the right hand and bring it down the right fide. 24. *Present your arms*; i. e. as explained in the three motions of the fourteenth word of command. 25. *To the right face*; i. e. bring up the firelock with a quick motion high before you, till your left hand comes even with your eyes, with the fingers of that hand extended along the lock, juft above the feather-fpring; the right foot to be brought clofe up to the left heel in this motion: face to the right taking care in facing to hold the firelock right up and down, and ready in your hands; ftep back with your right foot, and come down to your *prefent*, as in the foregoing explanation. 26. *To the right face*; i. e. as in the foregoing explanation, facing to the right. 27. *To the right about face*; i. e. as in the twenty-fifth explanation, only coming to the right about inftead of to the right. 28. *To the left face*; i. e. bring the right foot briskly to the hollow of your left, with the firelock in the fame pofition as in the firft motion of *facing to the right*; face to the left; come down to the *prefent*, as before. 29. *To the left face*; i. e. as in the foregoing explanation. 30. *To the left about face*; i. e. as before, coming to the left about inftead of the left. 31. *Shoulder your firelock*; i. e. as in the two motions of the nineteenth explanation. 32. *Charge your bayonet*; i. e. as in the firft explanation; bring the fwell of the firelock down ftrong upon the palm of the hand, grafping the piece at the fmall, behind the lock, and as high as the waift-belt; the firelock upon a level with the barrel upwards. 33. *Shoulder your firelock*; i. e. bring up the firelock to the fhoulder, place the left hand upon the butt, bringing the feet fquare to the front; quit the right hand, and throw it down the right fide. 34. *Advance your arms*; i. e. firft and fecond motions, as in the firft explanation; bring the firelock down the right fide, with the right hand, as low as it will admit without conftraint, ftepping up the left hand at the fame time to the fwell: the guard between the thumb and forefinger of the right hand, the three laft fingers under the cock, with the barrel to the rear; quit the left hand. 35. *Shoulder your firelock*; i. e. bring up the left hand, and feize it at the fwell; come fmartly up to the pofition; fhoulder. 36. *Prime and load*; i. e. come fmartly to the *recover*, by fpringing the firelock ftraight up with the left hand, turning the barrel inwards to the proper height of the recover; at the fame time that the left hand fprings the firelock, the right hand is raifed briskly along the right fide, and feizes the firelock across the breaft; as it rifes below the cock, the left hand comes with a quick motion from the butt, and feizes the firelock ftrong above the lock, the little finger of the left hand at the fpring of the lock, the left hand at an equal height with the face, the butt clofe to the body, but not preffed, the firelock perpendicular, oppofite the left fide of the face: bring the firelock down with a brifk motion to the priming pofition, the left hand holding the firelock, as in priming; the thumb of the right hand placed againft the face of the fteel, the fingers clinched, and the elbow a little turned out, that the wrift may be clear of the cock; open the pan by throwing up the fteel with a ftrong motion of the right arm, turning the elbow in and keeping the firelock ready in the left hand: handle your cartridge; prime; fhut your pan; caft about; load; draw rammers; ram down the cartridge; return the rammers; fhoulder. N. B. The motion of recover, and coming down to the priming pofition and opening pans, are to be done in the ufual time. The motions of handling cartridge to fhutting the pans, are to be done as quick as poffible: when the pans are fhut, a fmall paufe is to be made, and then caft about together; then the leading motions are to be done as quick as poffible; but before the rammer is returned, another fmall paufe is to be made, counting 1, 2, between each motion, till the firelock is fhouldered. *Prime and, make ready*; i. e. fpring the firelock briskly to the *recover*, keeping the left foot faft in this motion; as foon as the firelock is at the *recover*, without any ftop, fink the body briskly without ftooping forward, with a quick motion down upon the right knee; the butt-end of the firelock, at the fame time, falls upon the ground; the front part of the butt being in a line with the heel of the left foot. As foon as the butt comes to the ground, the firelock is to be cocked, immediately feizing the cock and fteel in the right hand; the firelock to be held firm in the left hand, about the middle of that part of the firelock between the lock and the fwell of the ftock; the point of the left thumb to be clofe to the fwell, pointing upwards. As the body is finking, the right knee is to be thrown as far back as the left leg may be

be right up and down; the right foot to be thrown a little to the right; the body to be kept ſtraight; the head up, looking to the right along the rank, the ſame as if ſhouldered; the firelock to be upright, and the butt about four inches to the right of the inſide of the left foot. *Preſent*, i. e. bring the firelock briſkly down to the *preſent*, by extending the left arm to the full length with a ſtrong motion; at the ſame time ſpring up the butt by the cock with the right hand, and raiſe up the butt ſo high upon the right ſhoulder, that you may not be obliged to ſtoop too much with the head; the right cheek to be cloſe to the butt, and the left eye ſhut, and look along the barrel with the right eye from the breech-pin to the muzzle; keep the left elbow down in an eaſy poſition, and ſtand as ſteady as poſſible; the thumb of the right hand to remain in the poſition as deſcribed in the third explanation of the manual. *Fire*; i. e. pull the trigger as directed in the manual; and as ſoon as the piece is fired, give yourſelf a ſtrong ſpring upon your left leg, raiſing your body briſkly, and ſtraight up, keeping your left foot faſt, and bringing the right heel to the inſide of the left; at the ſame time the firelock is to be brought up to the priming poſition, and half-cocked immediately; a ſhort pauſe is to be made, then handle cartridge, and go on with the loading motions deſcribed in the explanation of *prime* and *load*. *Centre rank, make ready*; i. e. ſpring the firelock briſkly to the *reverſe*, ſo ſoon as the left hand ſeizes the firelock above the lock the right elbow is to be nimbly raiſed a little, placing the thumb of that hand upon the cock; the fingers open by the plate of the lock, and as quick as poſſible force the piece to the cock, by dropping the elbow, and forcing down the cock with the thumb, ſtopping at the ſame time a moderate pace to the right, keeping the left foot faſt; as the firelock is cocked, the thumb is to fall below the cock, the right hand ſeizing the firelock cloſe under the cock, firmly; the fore-finger not to be before the trigger; the piece to be held in this poſition perpendicular, oppoſite the left ſide of the face, the butt cloſe to the left breaſt, but not preſſed; the body to be ſtraight, and as full to the front as poſſible; the head kept up, looking to the right of the rank, that the body and the firelock may not ſtoop forward, nor lean much out of the rank. *Preſent*; i. e. ſpring the firelock from the body to the arm's length with a quick motion, preſſing down the muzzle with the left hand, and ſpring up the butt with the right hand, as in the foregoing explanation of the *front-rank*. *Fire*. As in explanation 4, in the manual, with this difference, that the left foot is to be brought up to the right, at the ſame time that the firelock is brought down to the priming poſition. The loading motions as in the explanations of priming and loading, and at the laſt motion of ſhouldering, to ſpring to the left again, and cover the file leaders. *Rear rank make ready*; i. e. recover the firelock, and cock as before directed for the centre rank; as the firelock is recovered and cocked, ſtep briſkly ſtraight to the right, with the right foot a full pace; bring the left heel about ſix inches before the right foot; the body ſtraight, and as ſquare to the front as poſſible, as in explanation of the *centre rank*. *Preſent*. As in explanation *preſent*, before. *Fire*. As in explanation of the *centre rank*, and as the firelock is coming down to the priming poſition, the left is to be brought back to the right; and at the laſt motion of ſhouldering, to ſpring to the left again, and cover the file-leaders.

There are ſome peculiar words of command at the manual *exerciſe* of the grenadiers, when apart from the battalion; and alſo for the cavalry and artillery.

EXERCISE, *cavalry*, is of two ſorts; one huſtback and on foot. When a regiment is formed into ſquadrons, the ranks are to be arranged at the diſtance of twenty-four feet, and the files muſt keep toot-top to toot-top. In all wheelings, the flank which wheels, muſt come about in full gallop.

EXERCISE, *artillery*, is the method of teaching the regiments of artillery the uſe and practice of all the various engines of war, as of the light field-pieces of the garriſon and battering artillery, of the mortar and howits. See Smith's Milit. Dict. art. EXERCISE, WORDS of *command*. See *Exerciſe of* GUNS.

EXERCISE, in a *Naval Senſe*, is the preparatory practice of managing the artillery and ſmall arms, in order to make the ſhip's crew perfectly ſkilled therein, ſo as to direct its execution ſucceſsfully in time of battle. The words of command introduced, during the late war, for the *exerciſe* of the great guns, are the following; *Silence; caſt looſe your guns; level your guns; take out your lumpions; run out your guns; prime, point your guns; fire; ſponge your guns; load with cartridge; ſhift your guns; put in your lumpions; haule your guns*; and *ſecure your guns*. Falconer's Marine Dict. art. EXERCISE.

Exerciſe may alſo denote the execution of the movements, which the different orders and diſpoſitions of fleets occaſionally require, and which the ſeveral ſhips are required to perform, by means of ſignals.

EXERCISES, in the plural, are particularly underſtood of what is taught young gentlemen, in the academies, or riding-ſchools, &c. As, riding the great horſe, dancing, fencing, vaulting, drawing fortifications, &c.

EXERGASIA, *Exergaſia, Expoſition*, in *Rhetoric*, a figure, conſiſting of ſeveral equivalent expreſſions, or ſuch as are nearly ſo, in order to repreſent the ſame thing in a ſtronger manner.

EXERGUM, EXERGUE, or EXERGE, among *Medalliſts*, a word, motto, date, or the like, ſometimes found under the ground, whereon the figures are repreſented.

The word is derived from the Greek ἐξ, and ἔργον, *aſide, work*. Evelyn often writes it *exergo*.

Exergues are moſt commonly placed on the *reverſes*, though ſometimes, alſo, on the fronts, or face-ſides, of medals.

EXFOLIATION, compounded of *ex* and *folium*, *leaf*, in *Surgery*, the ſcaling of a bone, or its riſing, and ſeparating in leaves, or lamine.

Any part of the ſurface of the cranium that has been bared, is liable to *exfoliation*. The wound muſt not be ſtopped too much, but the bone left at liberty to recover itſelf, which it ſometimes does, without *exfoliating*, particularly in children.

EXFOLIATIVE. An *exfoliative* trepan is a trepan proper to ſcrape, and at the ſame time, pierce, a bone, and ſo to *exfoliate*, or raiſe, ſeveral leaves, or ſcales, one after another.

The uſe of the *exfoliative* trepan is very dangerous; as being apt to ſhake and diſorder the brain. See RASPATORY, and TREPAN.

EXPREDIART, in our *Old Writers*, denotes the breaking of the *peace*, or committing open violence. Leg. Hen. I. cap. 11.

The word is formed from the Saxon *freoſe, peace*.

EX GRAVI QUERELA, in *Law*, a writ that lies for him to whom any lands or tenements in fee are deviſed by will (within any city, town, or borough, wherein lands are deviſable by cuſtom) and the heir of the deviſor enters, and detains them from him. Reg. Orig. 234. Old Nat. Br. 87. And if a man deviſes ſuch lands or tenements unto another in tail, with remainder over in fee, if the tenant in tail enter, and is ſeiſed by force of the ſtatute, and afterwards dieth without iſſue, he in the remainder ſhall have the writ, *ex gravi querela*, to execute that deviſe. New Nat. Br. 441. Alſo where a tenant in tail dies without iſſue of his body, the heir of the donor, or he who hath the reverſion of the land, ſhall have this writ, in the nature of a *formedon* in the reverter. Ibid.

EXHÆREDATIO. See EXHEREDATION.

EXHALATION, a fumes or ſteam, *exhaling*, or iſſuing, from a body, and diſtuſing itſelf in the atmoſphere.

The terms *exhalation* and *vapour* are ordinarily uſed indifferently, but the more accurate writers diſtinguiſh them; appropriating the term *vapour* to the moiſt fumes raiſed from water and other liquid bodies; and *exhalation* to the dry ones emitted from ſolid bodies; as earth, fire, minerals, ſulphurs, ſalts, &c.

In this ſenſe, *exhalations* are dry, ſubtil corpuſcles, or effluvia, incenſed from hard terreſtial bodies, either by the heat of the ſun, or the agitation of the air, or ſome other cauſe; and emitted upwards to a certain height of the atmoſphere, where, mixing with the *vapours*, they help to conſtitute clouds, and return back again in dews, miſts, rains, &c.

Sir Iſaac Newton takes true and permanent air to be formed from the *exhalations* raiſed from the hardeſt and moſt compact bodies. See AIR, DAMP, EVAPORATION, and VAPOUR.

EXHAUSTED *receiver*, a glaſs, or other veſſel, applied on the plate of an air-pump, and having the *air* extracted out of it by the working of the engine. See AIR-*pump*.

Things placed in an *exhauſted receiver*, are ſaid to be in *vacuo*. See VACUUM.

EXHAUSTIONS, in *Mathematics*, Method of *exhauſtions*, is a way of proving the equality of two magnitudes, by a *reductio ad abſurdum*; ſhewing, that if one be ſuppoſed either greater or leſs than the other, there will riſe a contradiction.

The *method of exhauſtions* was of frequent uſe among the ancient mathematicians; as Euclid, Archimedes, &c.

It is founded on what Euclid ſays in his tenth book; viz. that thoſe quantities whoſe difference is leſs than any aſſignable quantity, are equal; for if they were unequal, be the difference ever ſo ſmall, yet it may be ſo multiplied, as to become greater than either of them; if not ſo, then it is really nothing.

This he aſſumes in the proof of prop. 1. book x. which, impoſſe,

imports, that if, from the greatest of two quantities, you take those that are half, and from the remainders more than its half, and so continually, there will, at length, remain a quantity less than either of those proposed.

On this foundation it is demonstrated, that if a regular polygon of infinite sides be inscribed in, or circumscribed about, a circle; the space, which is the difference between the circle and the polygon, will, by degrees, be quite exhausted, and the circle become equal to the polygon.

EXHEREMUM, in *Natural History*, the name of a white and smooth stone, used by the ancient artificers in polishing gold. It seems to be the same with the lapis Samius, a small smooth stone which they often found in the Samian earth.

EXHEREDATION, EXHEREDATIO, in the *Civil Law*, with us ordinarily called *disinheriting*, is the father's excluding his son from inheriting his estate.

There are fourteen causes of *exheredation* expressed in Justinian's Novels; without some one of which causes he decrees the exheredation null, and the testament inofficious, as the civilians call it.

Indeed, by the ancient Roman law, the father might pronounce *exheredation* without any cause; but the rigour of this law was restrained, and moderated, by Justinian.

EXHIBIT, in *Law*. When a deed, acquittance, or other writing, in a chancery suit, *exhibited* to be proved by witness; and the examiner writes on the back, that it was shewed to the witness at the time of his examination; this is called an *exhibit*.

EXHIBITION, a producing, or shewing, of titles, authorities, and other proofs, of a matter in contest.

Anciently, they used the phrase, *exhibition* of a tragedy, comedy, or the like; but now we say *representation*, in lieu thereof.

EXHIBITION, *Exhibitio*, in our *Old Writers*, is used for an allowance of meat and drink, such as was customary among the religious appropriators of churches, who usually made it to the depending vicar. The benefactions settled for the maintaining of scholars in the universities, but depending on the foundation, are also called *exhibitions*.

EXHORTATION, *Hortatio*, in *Rhetoric*, differs only from *suasion*, in that the latter principally endeavours to convince the understanding, and the former to work on the affections.

EXHUMATION, of *ex*, *out of*, and *humus*, *ground*, the act of digging up a body interred in holy ground, by the authority of the judge.

In France, the *exhumation* of a dead body is ordered, upon proof that he was killed in a duel. By the French laws, a parson has a right to demand the *exhumation* of the body of one of his parishioners, when interred out of the parish, without his consent.

EXIGENCE, or EXIGENCY, that which a thing requires, or which is expedient and suitable thereto.

EXIGENT, in *Law*, a writ which lies where the defendant, in a personal action, cannot be found, nor any thing of his within the county, whereby to be attached, or distrained.

It is directed to the sheriff, ordering him to proclaim and call the party five county-court days successively, and charge him to appear, under pain of outlawry.

The same writ also lies in an indictment of felony, where the party indicted cannot be found.

It is called an *exigent*, because it *exigity*, i. e. *exactis*, or requires the party to appear, or, by contempt, to suffer the law. If he appear not at the last day's proclamation, he is said to be *quinquies exactus*, and then is outlawed. See OUTLAWRY.

EXIGENTERS, four officers of the court of common pleas, who make all *exigents* and proclamations, in all actions where the process of outlawry lies.

Anciently, the making writs of *supersedeas* upon such exigents as failed in their offices, did likewise belong to them; but this branch of business was taken from them under king James I. and committed to a particular officer in the court of common-pleas, created by patent. See SUPERSEDEAS.

EXILE, *banishment*. See BANISHMENT.

Among the Romans, the word *exsul*, *exilium*, properly signified an interdiction, or exclusion from water and fire; the necessary consequence of which was, that the interdicted person must betake himself into some other country, where there was no living without fire and water.

Hinc, Cicero, *Ad Herennium*, observes, that the form of the sentence did not express *exile*, but only *aquæ & ignis interdictio*. See INTERDICTION.

The same author remarks, that *exile* was not properly a punishment, but a voluntary flying, or avoiding the punishment decreed: Exilium non *est supplicium, sed perfugium, portusque supplicii*. Pro Cæcina.

He adds, that there was no crime among the Romans, as among other nations, punished with *exile*; but *exile* was a recourse people flew voluntarily to, in order to avoid chains, ignominy, flarving, &c.

The Athenians frequently fent their generals, and great men, into *exile*, out of fear of their merits, or diftruft of the leaft great authority.

EXILE is fometimes alfo ufed for the relegating a perfon into a place, whence he is obliged not to ftir without leave.

The word is derived from the Latin *exilium*, or from *exul*, a banifhed perfon; and that, probably, from *extra folum*, out of his native foil.

Figuratively, we ufe the phrafe, *honourable exile*, for an office, or employment, which obliges a man to reftde in fome remote or diftant place.

Under the reign of Tiberius remote employments were a kind of myfterious *exile*. An ambaffador, or even a lord-lieutenancy, in Ireland, has been fometimes deemed a kind of *exile*. A refidence, or ramble, in fome barbarous country, is alfo a fort of *exile*.

EXILIUM, in *Law*, fignifies a fpoiling; and, by the ftatute of Northampton, is returned to the injury done to tenants, by abetting their tenure, ejecting them, &c. And alfo in the fame ftatute it is ufed for the difference between *wafte*, *deftruction*, and *exilium*. For he tells us, that *wafte* and *deftruction* are almoft the fame, and are properly applied to houfes, gardens, or woods; but *exilium* is when fervants are entrenched, and afterwards unlawfully turned out of their tenements. Fleta, lib. 1. cap. 11. Stat. Marlebridge 27.

EXINANITION, the fame as EVACUATION.

EXISTENCE, that whereby a thing has *an* actual effence, or is faid *to be*, *eft*.

The notion of *exiftence* is applicable not only to a created but an uncreated fubftance: but it muft be added, that the *exiftence* of created fubftances, and efpecially corporeal ones, implies a refpect to place, time, and even an efficient caufe; whence the fchoolmen generally define it, that whereby a thing is formally and extrinfically without (extra) its caufes, and that here, and now.

Exiftence and effence come very near the nature of each other; in effect, they only differ in that we have different manners of conceiving the fame thing.

For, 1. Effence is ufually explained either by the firft, nobleft, and radical attribute of the thing, e. gr. that of body, by extenfion; that of mind, by thinking, &c. or by fpecifying all the intrinfic attributes; and *exiftence*, either by fpecifying all place and all time as in that of God; or by fpecifying fome definite place, and time, together with the caufe, as in the creatures.

2. The foundation and occafion of this diftinction are this; that effence belongs to the queftion, *What is it? Quid eft?* but *exiftence* to the queftion, *Is it? An eft?*

3. *Exiftence* neceffarily pre-fuppofes effence, and cannot be conceived without it; but effence may be conceived without *exiftence*, in that effence belongs equally to things that are *in exiftentia*, and *in actu*; but *exiftence* only to thofe *in actu*. Note, however, that this does not obtain in God, whofe nature and effence the mind cannot think without conceiving his *exiftence*.

We have divers ways of arriving at the knowledge of the *exiftence* of things. Our own *exiftence* we know by intuition; that of *exiftence* of a God, by demonftration; and that of other things, by fenfation.

As for our own *exiftence*, we perceive it fo plainly, that it neither needs, nor is capable of any proof. In every act of fenfation, reafoning, or thinking, we are confcious to ourfelves of our own being, and in this matter come not fhort of the higheft degree of certainty.

As to our knowledge of the *exiftence* of a God, though he has given us no immediate view of himfelf, yet, having furnifhed us with faculties of mind, perception, and reafon, we can never want a clear proof thereof. See GOD.

The knowledge of the *exiftence* of other things, i. e. of external objects, bodies, a world, &c. we only have by fenfation; for there being no neceffary connection of real *exiftence* with any idea a man hath in his memory, nor of any other *exiftence* but that of God, with the *exiftence* of any particular thing; no particular man can know the *exiftence* of any other being, but only when, by actually operating upon him, it makes itfelf be perceived by him.

The having of the idea of any thing in our mind, no more proves the *exiftence* of that thing than the picture of a man evidences his being in the world, or the vifions of a dream make a true hiftory. It is, therefore, the actual receiving of ideas from without that gives us notice of the *exiftence* of other things, and makes us know that fomething doth *exift* at that time without us, which caufes that idea in us, though we neither know nor confider how it doth it.

This notice which we have by our senses, of the *existence* of things without us, though it be not altogether so certain as intuition and demonstration, yet deserves the name of knowledge, if we persuade ourselves, that our faculties act and inform us right concerning the *existence* of those objects that affect them.

Now, besides the assurance of our senses themselves, that they do not err in the information they give us of the *existence* of things without us, we have other concurrent reasons: as, 1. It is plain those perceptions are produced in us by exterior causes affecting our senses; because those that want the organs of any sense never have the ideas belonging to that sense produced in their minds. 2. Because we find we cannot avoid having those ideas produced in our minds. When our eyes are shut, we can at pleasure recal to our mind the ideas of light or the sun, which former sensations had lodged in our memories; but if we turn our eyes towards the sun, we cannot avoid the idea which the light or the sun then produces in us, which shews a manifest difference between those ideas laid up in the memory, and such as force themselves upon us, and we cannot avoid having; besides, there is no one who doth not perceive the difference in himself between actually looking upon the sun, and contemplating the idea he has of it in his memory; and therefore he hath certain knowledge, that they are not both memory or fancy. 3. Add to this, that many ideas are produced in us with pain, which we afterwards remember without the least offence; thus, the pain of heat, or cold, when the idea of it is received in our mind, gives us no disturbance, which, when felt, was very troublesome; and we remember the pain of hunger, thirst, head-ach, &c. without any pain at all, which would either never disturb us, or else constantly do it, as often as we thought of it, were there nothing more but ideas flitting in our minds, and appearances entertaining our fancies, without the real *existence* of things affecting us from abroad. 4. Our senses, in many cases, bear witness to the truth of each other's report concerning the *existence* of sensible things without us: he that doubts, when he sees a fire, whether it be real, may feel it too if he please; and, by the exquisite pain, may be convinced, that it is not a bare idea or phantom. Such is Mr. Locke's demonstration of the *existence* of external bodies.

The ingenious Dr. Berkeley has a different system; external bodies, he contends, have no *existence*, but in a mind perceiving them; that is, they only *exist, quatenus*, they are perceived; and of this he has given us what he and many others account a demonstration.

In reality, "that neither our thoughts, passions, nor "ideas, formed by the imagination, exist without the "mind, he observes, is allowed; and that the various "sensations imprinted on the mind, whatever objects "they compose, cannot exist otherwise than in a mind "perceiving them, is not less evident. This appears "from the meaning of the term *exist*, when applied to "sensible things. Thus, the table I write on, *exists*, i. e. "I see and feel it; and were I out of my study, I should "say it *existed*; i. e. that were I in my study I should see "and feel it as before. There was an odour; i. e. I "smelt it, &c. but the *existence* of unthinking beings, "without any relation to their being perceived, is un-"intelligible, their *esse* is *percipi*." The notion of bodies, he endeavours to shew, is founded on the doctrine of abstract ideas: "What are light and colours, heat "and cold, extension and figure; in a word, the things "we see and feel, but so many sensations, notions, ideas, "or impressions on the sense? And is it possible to se-"parate, even in thought, any of these from perception? "The several bodies, then, that compose the frame of "the world, have not any subsistence without a mind: "their *esse* is to be perceived or known: and as long as "they are not perceived by me, nor any other thinking "being, they have no being or *existence* at all. The "things we perceive, are colour, figure, motion, &c. "that is, the idea of those things; but has an idea any "*existence* out of the mind? To have an idea is the "same thing as to perceive; that, therefore, wherein "colour, figure, &c. exist, must perceive them. It is "evident, therefore, there can be no unthinking substance or substratum of those ideas: but you may argue, "if the ideas themselves do not exist without the mind, "there may be things like them, whereof they are co-"pies or resemblances, which exist without the mind. "It is answered, an idea can be like nothing but an "idea; a colour or figure can be like nothing else but "another figure or colour. It may be further asked, "whether those supposed originals, or external things, "whereof our ideas are the pictures, be themselves per-"ceivable or not? If they be, they are ideas; if they "be not, I appeal to any one, whether it be sense to "say, a colour is like somewhat which is invisible; "hard or soft, like somewhat intangible, &c. Some distinguish between primary and secondary qualities; "the former, viz extension, solidity, figure, motion, "rest, and number, they maintain have a real *existence* "out of the mind; as for the latter, under which come "all other sensible qualities, as colours, sounds, tastes, "&c. they allow the ideas we have of them are not resemblances of any things existing without the mind, "or unperceived, but depend on the size, texture, mo-"tion, &c. of the minute particles of matter. Now, "it is certain, that those primary qualities are inseparably united with the other secondary ones, and cannot "even in thought be abstracted from them, and there-"fore must only exist in the mind. Can any man con-"ceive the extension and motion of a body without its "other sensible qualities? For my part, I find it im-"possible to frame an idea of a body extended and mov-"ing, without giving it some colour, &c. In effect, "extension, figure, and motion, abstracted from all "other qualities, are inconceivable: where the others, "therefore, are, there these too must be, i. e. in the "mind, and no where else. Again, great and small, "swift and slow, are allowed to exist no-where with-"out the mind, being merely relative and changing, as "the frame or position of the organ changes: the ex-"tension, therefore, that exists without the mind, is "neither great nor small, the motion neither swift nor "slow; i. e. they are nothing. That number is a crea-"ture of the mind, is plain (even though the other "qualities were allowed to exist) from this; that the "same thing bears a different denomination of number, "as the mind views it with different respects; thus, the "same extension is 1, or 3, or 36, as the mind con-"siders it, with reference to a yard, a foot, or an inch. "Nay, many of the modern geometricians hold, that a "finite line may be divided into an infinite number of "parts, and each of those infinitesimals into an infinity "of others; and so on, *in infinitum*; so that the same "thing is either unity or infinity, either no number or "all number. In effect, after the same manner as the "modern philosophers prove colours, tastes, &c. to "have no *existence* in matter, or without the mind; the "same thing may be proved of all sensible qualities "whatsoever: thus, they say, heat and cold are only "the affections of the mind, not at all patterns of real "beings existing in corporeal substances; because the "same body which seems cold to one hand seems warm "to another. Now, why may we not as well argue, "that figure and extension are not patterns or resem-"blances of qualities existing in matter; because to the "same eye, at different times or eyes of different "structure, at the same station, they appear various? "Again, Sweetness, it is proved, does not exist in the "thing tasted, because the thing remaining unaltered, "the sweetness is changed to bitterness, as in a fever, "or by an otherwise vitiated palate. Is it not as reason-"able to say, that motion does not exist out of the mind? "since, if the succession of ideas in the mind become "swifter, the motion, it is acknowledged, will appear "slower, without any external alteration. Again, were "it possible for solid figured bodies to exist out of the "mind, yet it were impossible for us ever to know it: "our senses, indeed, give us sensation of ideas, but do "not tell us that any things exist without the mind, or "unperceived, like those which are perceived: this the "materialists allow. No other way therefore remains, "but that we know them by reason's inferring their "*existence* from what is immediately perceived by sense. "But how should reason do this, when it is confessed, "there is not any necessary connection between our sen-"sations and these bodies? It is evident, from the "phenomena of dreams, phrenzies, &c. that we may be "affected with the ideas we have now, though there "were no bodies existing without them; nor does the "supposition of external bodies at all forward us, in "conceiving how our ideas should come to be produced. "The materialists own themselves unable to conceive in "what manner body can act on spirit, or how it should "imprint any idea on the mind. To suppose, there-"fore, bodies existing without the mind, is little else "than to suppose God has created innumerable beings "entirely useless, and serving to no purpose at all. On "the whole it appears, that the *existence* of bodies out "of a mind perceiving them, is not only impossible, and "a contradiction in terms; but were it possible, nay "real, it were impossible we should ever know it. Also "again, that supposing that there are no such things, "yet we should have the very same reason to suppose "there were that we now have. Suppose, e.gr. an in-"telligence affected with the same train of sensations, "imprinted in the same order, and with the same vivid-"ness,

" ness, would it not have all the reason to believe the
" *existence* of bodies represented by his ideas that we have?
" All our ideas and sensations are visibly inactive; nay,
" the very being of an idea implies passiveness and in-
" activeness; so that it is impossible for an idea to do any
" thing, or, in strictness, be the cause of any thing: it
" cannot, therefore, be the resemblance or pattern of
" any active being, unless opposites can be said to re-
" semble one another. Now, we find a continual suc-
" cession of ideas in the mind; but these, it has been
" proved, do not depend on any external body as their
" cause; it remains, therefore, that their cause is an in-
" corporeal active substance or spirit: for that I am not
" the cause of my own ideas, is plain from this, that
" when I open my eyes in broad day-light, I cannot help
" seeing various objects. Now, the fixed rules or me-
" thods wherein the mind we depend on excites in us
" the ideas of sense, are called *laws of nature*; these we
" learn by experience, which teaches us, that such and
" such ideas are attended with such and such other ideas
" in the ordinary course of things. Ideas are not any
" how, and at random, produced; there is a certain
" order and connection established among them, like
" that of cause and effect; and those are several combi-
" nations of them made in a very regular artful manner,
" which we call *bodies*; and the system of those, *the*
" *world*. In strictness, however, the connection of ideas
" does not imply the relation of cause and effect, but
" only of a mark or sign of the thing signified: the fire
" I see is not the cause of the pain I feel, but the mark
" that forewarns me of it; the noise I hear is not the
" effect of this or that motion or collision of natural bo-
" dies, but the sign thereof. The Cartesians own some-
" what like this; the action of bodies in our organs, say
" they, is not the efficient cause of our ideas and per-
" ceptions, but only the occasional cause, which deter-
" mines God to act on the mind, according to the laws
" of the union of the soul and body." See CAUSE. Dr. Berkeley, indeed, taking away bodies, takes away what these philosophers account the occasions of their ideas: "by an occasion, he says, must either be meant
" the agent that produces an effect, or something ob-
" served to accompany or go before it in the ordinary
" course of things; but matter is allowed to be passive
" and inert, and cannot therefore be an agent or efficient
" cause; and this matter primitively, and in itself, is al-
" lowed imperceivable, and devoid of all particular sen-
" sible qualities; i. e. it has not this or that particular
" colour, this or that particular figure, &c. but has co-
" lour in the general, figure in the abstract, &c. but an
" abstract is no object of sense; matter, therefore, can-
" not be the occasion of our ideas in the latter sense."
See Berkel. Princip. of Human Knowl. See ABSTRACTION.

How far the great argument of the maintainers of a material world from the impossibility of God's deceiving us and from the evidence that he does so, if there be no such thing, will go against this reasoning, we leave to the reader. See Stanl. Hist. Philosoph part xii. p. 816. where the objections of the ancient Pyrrhonists to the *existence* of bodies are recited.

As to the *existence* of spirits, Mr. Locke allows, that our having ideas of them does not make us know that any such things do exist without us; or that there are any finite spirits, or any other spiritual beings, but God. We have ground from revelation, and several other reasons, to believe with assurance that there are such creatures; but our senses being not able to discover them, we want the means of knowing their particular *existence*: for we can no more know that there are finite spirits really existing by the idea we have of such beings, than by the ideas any one has of fairies or centaurs, he can come to know that things answering to those ideas do really exist.

EXIT, properly expresses the departure of a player from off the stage, when he has acted his part.

The word is also used in a figurative sense, to express any kind of departure, even death.

EXITERIA, Ἐξίτηρια, in *Antiquity*, oblations or prayers to any of the gods for a prosperous expedition or journey. There were also feasts under this denomination, which were celebrated by the Greeks with sacrifices and prayers, when their generals undertook expeditions against any enemy.

EXITUS, *Issue*, in *Law*, the yearly rents or profits of lands or tenements. See ISSUE, &c.

EXLEGALITUS, in *Law*, the same with an outlawed person. See OUTLAW.

EX MERO MOTU, formal words used in the king's charters and letters patent, signifying that he does what is contained therein of his own will and motion.

The effect of these words is to bar all exceptions that might be taken to the instrument, by alledging that the prince in passing such charter was abused by false suggestion.

EXOCATACŒLUS, in *Antiquity*, a general denomination, under which were included several grand officers of the church at Constantinople; as, the grand œconomus, grand sacellarius, grand master of the chapel, grand sceuophylax or keeper of the vessels, grand chartophylax, the master of the little chapel, and the protecdicus, or first advocate of the church.

There are many opinions with respect to the etymology of this term. P. Goar apprehends, that all the inferior priests were called Καλλιανοὶ, *canarei*, q. d. people of a low condition; and that their superiors were called *exocatacœli*, q. d. people out of the number of *canarei*, or above them. Upon the whole, however, he adheres to the sentiment of G. Cornelius, who says, that the patriarchal palace, and the apartments of the syncellus, and of the monks in the patriarch's service, were in a very low part of the city, which, with regard to the rest, seemed a valley or pit; and that the officers above mentioned had their several houses or prospects *from*, out of the valley; whence the name *exocatacœli*. M. Du-Cange derives the appellation from their being above the level or rank of the other clerks, and seated at church, &c. in more honourable places erected for that purpose on either side of the patriarch's throne.

The *exocatacœli* were of great authority: in public assemblies they had the precedence of bishops; and in the patriarchate of Constantinople did the office of deacons, as the cardinals originally did in the church of Rome. Accordingly, in the letter of John IX. to the emperor Basilius Leo, they are called *cardinales*.

At first they were priests; but some patriarchs of Constantinople, whom Codin does not mention, would have them for the future to be no more than deacons. The reason was, that being priests, each of them had their several churches, wherein they were to officiate on all the grand festival days; so that it unhappily fell out, the patriarch on the most solemn days was deserted by all his chief ministers.

EXOCIONTES, Ἐξοκιόντες, in *Church-history*. The Arians were first called *Exocionites*, because, when expelled the city by Theodosius the Great, they retired into a place called *Exocionium*, and there held their assemblies. Justinian gave the orthodox all the churches of the heretics, excepting that of the *Exocionites*.

The word is derived from Ἔξωσις, or Ἐξώσιον, the name of the place above mentioned. Codin, in his Origines, says, that the *Exocionium* was a place encompassed with a wall, built and adorned by Constantine; and that without the circumference of the wall there was a column, with a statue of that emperor, whence the place took its name, viz. from ἔξω, *without*, and κίων, *column*.

EXOCŒTUS, in *Ichthyology*, the name of a genus of fishes, of the order of *abdominales* in the Linnæan system, and in the Artedian, of the malacopterygious or soft-finned kind; the characters of which are these: the branchiostege membrane contains ten bones, four of which are broad, and are covered by the opercula of the gills, and all of them are very difficult to be counted. The pectoral fins are very long: there is but one fin on the back, and that is placed toward the lower part of it. The scales are large. Artedi and Linnæus enumerate only two species of this genus. See *Ich. IV. Fish.* No. 41. and article FLYING-*fish*.

EXODIARY, EXODIARIUS, in the *Ancient Roman Tragedy*, was a droll, or mime, who appeared on the stage when the tragedy was ended, and performed what they called the *exodium*, or conclusion of the shew, to divert the company.

EXODIUM, Ἔξοδιον, in the *Ancient Greek Drama*, was one of the four parts or divisions of a tragedy.

The word is formed from the Greek, ἔξοδος, *going out, departure*, of ἐξ and ὁδὸς, *way, road*. Pollux, lib. iv. cal. 8. it *exitus*.

The *exodium*, according to Aristotle, was so much as was rehearsed after the chorus had ceased to sing for the last time; so that *exodium* with them was far from being what the epilogue is with us, as several people have imagined it was.

The *exodium* was so much of the piece as included the catastrophe and unravelling of the plot; which catastrophe, &c. in pieces regularly composed, always began after the last singing of the chorus, answering nearly to our fourth and fifth acts. M. Dacier's Comment. on Aristotle's Poetic, chap. 12. See CATASTROPHE and CHORUS.

Among the Romans the *exodium* was a different thing; it was pretty nearly what farces are with us. After the tragedy was over, came a pantomime on the stage, call-

ed

ed the *exoletarii*, who, by his grimace, jesting and buffoonery, diverted the people, composed their minds, and wiped away the tears which the tragic spectacle had occasioned to be shed.

Vignier on T. Livy says, the *exodium* consisted of certain humorous, drolling verses, rehearsed by the youth at the end of the *fabulæ atellanæ*, and answering to our farces. In another place, the same author says, that the *exodia* were a kind of interludes in the intervals between the acts, partly fable and pleasantry, partly music, &c. to give time both for the spectators and actors to recover breath. The passage in Livy, whence he takes the notion, is lib. vii. dec. 1. *Ridicula intenta versibus, quæ juventus inter se more antiquo jactare cœpit, exque conserta sunt fabulis pæsiffimum atellanis.* See also Juvenal.

Urbanis exodia risum movet atellana
Gestibus Autumni.

EXODIUM, in the *Septuagint*, signifies the end or conclusion of a feast.

The Hebrew text calls the day עצרת, which the Seventy render Ἔξοδον.

In particular, *exodium* is used for the eighth day of the feast of tabernacles, which, it is said, had a special view to the commemoration of the Exodus, or departure out of Egypt, though there is nothing of it expressed in Scripture.

EXODIUM, was also the name of a song sung at the conclusion of a meal or feast.

EXODUS, the second of the five books of Moses.

The word in its original Greek, Ἔξοδος, literally imports a *going out*, or *journey*; and was applied to this book, because the history of the Israelites' passage out of Egypt is related therein. Beside this, it contains the story of what was transacted in Egypt from the death of Joseph to the delivery of the Jews; as well as what passed in the wilderness, and particularly at mount Sinai, to the building of the tabernacle.

The Hebrews call it *veel'leh schemoth*, q. d. *hæc nomina*, these are the initial words of the book; for the same reason they call Genesis, *bereschit*, q. d. *in principio, in the beginning.*

EX OFFICIO, denotes the power a person has in virtue of his office, to do certain things without being applied to.

By a branch of statute 1 Eliz. the queen, by her letters patent, might authorise any persons exercising ecclesiastical jurisdiction to administer an oath, *ex officio*, whereby supposed offenders were forced to confess, accuse, or clear themselves of any criminal matter, &c. but this branch relating to this oath is repealed by 17 Car. I. cap. 11.

Ex officio *Informatur.* See Information.

EXOLICETUS, in *Natural History*, a name used among the writers of the middle ages, to express a small stone which had such a variety of colours that it dazzled, as they say, people's eyes in looking at them. It is said to have been found in Lybia. The name is probably only a corruption of the hexacontalithos of Pliny and the older writers; and this seems to have been no other than a name for the opal.

EXOMIS, of ἐξ, *out of*, and ὦμος, *shoulder*, in *Antiquity*, a strait narrow garment through which the shoulders appeared. It had something in common with the tunic, and something with the pallium. It was worn by slaves, servants, and the lower classes of people among the Romans.

EXOMOLOGESIS, Ἐξομολογησις, formed of Ἐξομολογεῖσθαι, *I confess*, a term little used but in speaking of the ancient ceremonies of repentance, wherein the *exomologesis*, by us called *confession*, was a part.

Some of the ancients, and particularly Tertullian, de Pœnit. cap. 9. use the word in a greater latitude, as comprehending the whole of repentance.

A public *exomologesis* was never commanded by the church for secret sins, as may be seen in the capitulars of Charlemagne, and the canons of divers councils.

EXOMPHALUS, Ἐξόμφαλος, of ἐξ, *out*, and ὀμφαλος, *navel*, in *Surgery*, a general name, comprehending all kinds of navel-ruptures. The first are tumors or swellings of the solid parts, wherein there are three varieties, denominated from the several parts affected, as the *enterompholus*, *epiplomphalus*, and *enter-epiplomphalus*. The second are tumors formed by collections and gatherings of humours, of which there are four varieties, distinguished by the particular humours they are formed of, as the *hydromphalus*, *pneumatomphalus*, *sarcomphalus*, and *varicomphalus*. The third are those compounded of both the other, viz. the *enterohydromphalus* and *epiplosarcomphalus*. See each species under its several head.

In one of those cases which Mr. Mery has given an account of, the infant was born alive, but died after fourteen hours; the tumor was very large; and on opening it the liver, spleen, stomach, and intestines, were found all inclosed in it; yet its aperture at the navel was but little more than an inch in diameter. The most natural conjecture in this case seemed, that the viscera had been forced out of the body by some accident during pregnancy, and that the peritoneum, as they enlarged in growth, had extended itself by degrees to the dimensions of this sack: but, on a strict enquiry, the sack was found to be composed of a double membrane; so that it could not be a production of the peritoneum, which is single, but it must necessarily have been an extension of the membranes of the placenta, which, uniting, form the umbilical cord; and it was not less easy to determine that the viscera could not have been forced out of the body when at any considerable growth, as the aperture was so small, the liver alone being of six times its diameter. It appears, therefore, that in those cases the viscera get out while very small, and grow and enlarge in their unnatural situation. The parent of the infant being asked if she had received any injury during her pregnancy, could not recollect any; but only observed, that while young with child, she had been very strongly affected by the sight of the entrails of an ox hanging out of its belly at a butcher's. Mem. Acad. Par. 1716. See Hernia.

EXONEIROSIS, from ἐξ, *out*, and ὄνειρος, *dream*, a nocturnal pollution or emission of the semen in dreams. This, if it happens but rarely, is usually a sign only of redundant vigour; but if it happens frequently, is a sign of weakness of the seminal vessels, which is most frequently the case.

EXONERATIONE *sectæ*, in *Law*, a writ that lay for the king's ward, to be freed from all suit to the county-court, hundred-court, leet, &c. during the wardship. F. N. B. 158.

EXONYCHOS, of ἐξω, *without*, and ὀνυξ, a *nail*, in *Botany*, a name given by some of the ancient writers, among whom are Dioscorides and Pliny, to the Cronwell or lithospermum. See Μονονυχιον.

EXOPHTHALMIA, of ἐξ, *out*, and ὀφθαλμος, *eye*, in *Surgery*, is a protuberance of the eye out of its natural position.

EXORCISM, Ἐξορκισμος, prayers or conjurations wherewith to *exorcise*, *i. e.* drive out devils or demons from persons apprehended to be possessed or to preserve from danger. The word is derived from the Greek, ἐξορκιζειν, *adjurare*, *conjurare*, *to adjure*, or *conjure*. In most dictionaries, *exorcism* and conjuration are used as synonymous; but, in reality, conjuration is only a part of the *exorcism*; and the *exorcism* the ceremony entire. The conjuration is properly the formula, where the devil is commanded to come forth, &c.

Exorcisms are of great use in the Romish church: their prelates, &c. are frequently exorcising dæmoniacal persons. The priests make holy water by exorcising common water a certain number of times. In reality, the *exorcism* is a part in most of their consecrations.

Exorcisms had anciently another and farther purpose; being applied by way of trial or purgation to exort the truth from the accused.

The *exorcism*, in this sense, was a sort of bread conjured and exorcised for the purpose; and the opinion was, that if the person was criminal he could not swallow the bread.

This, it seems, was a frequent practice in the time of our Edward III. and the bread thus exorcised was said to be corsned.

Lindenbrock gives instances of *exorcisms* with barley-bread, and others with cheese; and hence, probably, might arise that popular imprecation, "May this bread "choak me, if I tell a lye." See Ordeal and Judicium *Dei*.

EXORCIST, in the *Romish Church*, a priest, or tonsured clerk who has received the four lesser orders, one of which is that of *exorcist*.

The term is likewise applied to a prelate, or to a priest delegated by a prelate, who actually exorcises a person possessed.

It is a dispute among divines whether ever the Greeks had any such order as that of *exorcist*. Fa. Goar, in his Notes on the Greek Euchologion, has made it probable they had, from several concurring passages in St. Dionysius and St. Ignatius Martyr.

The ordination of *exorcists* is performed in the time of mass, their principal office being to expel devils. The fourth council of Carthage, can. 7. appoints, that in the ordination of *exorcists*, the bishop, putting the book of exorcisms in their hands, shall say these words: "Receive it, and keep it in remembrance, and have power "to lay hands on *energumeni*, whether baptised or cate-"chumens;" which form still obtains.

M. Fleury

M. Fleury mentions certain people among the Jews who travelled round the country, making profeſſion of driving out devils by invocations, which they pretended, had been taught them by Solomon: theſe were alſo called *exorciſts*. See Joſeph. Antiq. Jud. lib. viii. cap. 2. Origen. Tract. xxxv. in Matt. 35. 63.

EXORDIUM, in *Oratory*, the preamble or beginning of a diſcourſe or ſpeech, ſerving to prepare the audience, and introduce the matter in hand.

The word is formed from the Latin *ordiri, to begin*, by a metaphor taken from the weavers, who are ſaid, *ordiri telam, to begin or warp a web* by diſpoſing and ordering the threads in a certain manner for the future work. See WARP.

The *exordium*, on other occaſions, is called the *prologue*, *proem*, and *preface*.

Cicero defines *exordium*, a part of an oration, whereby the minds of the audience are duly prepared for what remains to be ſaid. The *exordium* is a part of principal importance, and is to be laboured with extraordinary care; whence Tully calls it *difficilima pars orationis*.

Exordiums are of two kinds; either juſt and formal, or vehement and abrupt. In the firſt, the audience is prepared and conducted by due and eaſy ſteps; in the ſecond, the orator, as if ſeized with ſome ſudden paſſion, breaks out upon his audience at once. Such is that *exordium* of Iſaiah; *Hear, O heavens! and give ear, O earth!* Or that of Cicero againſt Catiline: *Quouſque tandem abutere patientia noſtra, Catilina?* Abrupt *exordiums* are moſt ſuitable on occaſions of extraordinary joy, indignation, or the like; though we have inſtances of panegyrics of the greateſt orators, begun abruptly, without any ſuch occaſions. Such is that of Gorgias, who began his elege of the city and people of Elis with HAIL, WHITE-FOOTED, *Elis beata civitas*. Abrupt, bally, *exordiums*, were more to the taſte and manner of the Greeks than of the Latins. The objects which the orator ſhould have in view in this part of his diſcourſe, are to gain the good opinion of his hearers, to ſecure their attention, and to give them ſome general notion of his ſubject; and therefore the requiſites in an *exordium* are, 1. *Propriety*, whereby the *exordium* appears eaſy and natural, becomes of a piece with the whole diſcourſe, and matches it as a part does the whole; ſo that it could not be accommodated to any other, or, perhaps, a contrary occaſion. The ancient orators were very deſective in this point; their *exordiums* had frequently nothing in common with the ſubject.

2. *Modeſty*, or an ingenious bathfulneſs, which recommends the orator exceedingly to the favour of his audience. This is what Cicero calls ſo much in L. Crafſus, *Fuit enim in L. Craſſo pudor quidam, qui non modo non obeſſet ejus orationi, ſed etiam probitatis commendatione proderet.* The ſame Tully owns of himſelf, that at the beginning of his oration every limb trembled, and his whole mind was in a flutter. The vain glory of that mother ſhould be carefully avoided, of whom Horace ſpeaks, and who began his poem *Fortunam Priami cantabo & nobile bellum*.

3. *Brevity*, not amplified or ſwelled with a detail of circumſtances, or a long circuit of words; and in this reſpect it ſhould be accommodated to the length of the diſcourſe.

4. The ſtyle of the *exordium* ſhould be juſt, eaſy, and pleaſant. Quinctilian facetiouſly compares a faulty *exordium* to a fcarred face, which is preſently diſcerned, and very diſagreeable. Thus Cicero, *Feſtibula, acuiſque ad cauſam facies illuſtres*.

The *exordium* appears an eſſential part of an oration; though anciently, in the Areopagus, Julius Pollux tells us they ſpoke without any *exordium*, and paſſions, and any peroration or epilogue. The like is ſaid to have been done by Xenophon, who began thus: *Darius & Pariſatis duos habuere filios*.

EXORMISTOS, in *Ichthyology*, a name given by ſome of the old writers to that ſpecies of the *petromyzon* which other authors call the *lampetra fluviatilis*, and we in Engliſh the *lamprey*. This is diſtinguiſhed by Artedi by the name of the *petromyzon*, with only one ſeries of ſmall teeth in the verge of the mouth, and ſome large ones below. See MUSTELA, LAMPETRA, and PETROMYZON.

EXOS *ſpicil*, in *Ichthyology*, a name given by Geſner and Rondeletius to the fiſh which we call the *huja* or *ichthyocolla piſcis*, from the drug called *ichthyocolla*, or *piſcis glus*, being procured from it. It is properly a ſpecies of the acerpenſer, and is diſtinguiſhed from the common STURGEON by its having no tubercles. See ACCIPENSER.

EXOSTOSIS, from ἐξ, *out*, and ὀστεον, a *bone*, in *Anatomy*, is properly an acute eminence or exceſſrence, puſhing preternaturally above the bone, but creating ſometimes no diſturbance, pain, or deformity, and unaccompanied with a caries or ſpina ventoſa. When this is the caſe, it is always beſt to let it alone; for the attempt to remedy often proves much worſe than the diſeaſe; and by laying the bone bare, a caries, or other inconvenience is brought on. On the other hand, when this diſorder occaſions pain or deformity, or impedes any action, or produces other miſchief, it may be remedied by taking off the protuberant part of the bone in the ſame manner as in caſes of the SPINA *ventoſa*.

EXOSTRA, in the *Ancient Theatre*, a place where ſuch parts of the play were recited as were ſuppoſed to be acted privately in the houſe.

EXOSTRA, was likewiſe the name of a warlike engine uſed in the ſieges of towns.

EXOTERIC and ESOTERIC, are terms denoting *external* and *internal*, and applied to the double doctrine of the ancient philoſophers: the one was public, or *exoteric*; the other ſecret, or *eſoteric*. The firſt was that which they openly profeſſed and taught to the world; the latter was confined to a ſmall number of choſen diſciples. This method was derived originally from the Egyptians, who, according to the united teſtimony of Herodotus, Diodorus Siculus, Strabo, Plutarch, &c. had a twofold philoſophy, one ſecret and ſacred, another public and common. The ſame practice alſo obtained among the Perſian Magi, the Druids of the Gauls, and the Brachmans of India. The Egyptian prieſts, with whom it originated, ſuſtained the character of judges and magiſtrates, and probably introduced this diſtinction with a view to the public welfare, and to ſerve the purpoſes of legiſlation and government. Clement of Alexandria informs us, that they communicated their myſteries principally to thoſe who were concerned in the adminiſtration of the ſtate; and Plutarch confirms the ſame declaration. However, others have ſuppoſed that they invented the fables of their gods and heroes, and the other external ceremonies of their religion, to diſguiſe and conceal natural and moral truths; whatever was the motive of their [illegible] and whether applied to political purpoſes.

EXOTIC, ἐξωτικος, a term uſed in ſignifying *foreign*, or *extraneous*, i. e. ſomething coming from a remote or ſtrange country. In which ſenſe it is ſometimes toy, *exotic*, or *barbarous term or word*.

The word is derived from the Greek, ἐξω, ἐξωθεν, *extra, without, on the outſide*.

EXOTIC, is chiefly applied to plants which are natives of foreign countries, particularly thoſe brought from the Eaſt and Weſt Indies, and which do not naturally grow in Europe.

The generality of *exotics*, or *exotic* plants, do not thrive in England without ſome peculiar care and culture; they require the warmth of their own climates; whence the uſe of hot-beds, glaſs-frames, green-houſes, &c. See GREEN-*houſe*, and STOVE.

In ſending plants from one country to another, great cautions are neceſſary. The plants ſent from a hotter country to a colder ſhould be always put on board in the ſpring of the year, that the heat of the ſeaſon may be advancing as they approach the colder climates; and on the contrary, thoſe which are ſent from a colder country to a hotter ſhould be ſent in the beginning of winter.

The beſt way of packing up plants for a voyage, if they be ſuch as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as cloſe together as may be; the plants ſhould be ſet in theſe boxes three weeks before they are to be put on board, and in good weather they ſhould be ſet upon the deck, and in bad removed or covered with a tarpaulin.

If they are going from a hotter country to a cold one, they muſt have very little moiſture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely; and being ſhaded from the heat of the ſun, they will come ſafe.

Many plants, however, will live out of the earth a great while; as the ſedums, euphorbiums, ficoides, and other ſucculent ones. Theſe need no other care than the packing of them up with moſs in a cloſe box; and there ſhould be a little hay put between them, to prevent them from wounding or bruiſing one another, and holes bored in the boxes to keep them from heating and putrefying. In this manner they will come ſafe from a voyage of two or three, or even four or five months.

Several trees alſo will come ſafely in the ſame manner, taking them up at a ſeaſon when they have done growing, and packing them up with moſs. Of this ſort are oranges, olives, capers, jaſmines, and pomegranate-trees. Theſe, and many others, are annually brought over thus from Italy; and though they are three or four months in the paſſage, ſeldom miſcarry. And the beſt way of ſend-

ing over feeds is in their natural husks, in a bag or packed up in a gourd-shell, keeping them dry, and out of the way of vermin. Miller.

Dr. Lister has a discourse in the Philosoph. Trans. on *Exotic Diseases*, i. e. such diseases as are never bred among us, but brought, from time to time, by infection, from other countries. Such, according to this author, are, 1. The *plague*, which is properly a disease of Asia, where it is epidemic. 2. The *small-pox*, which is an oriental disease, and not known to Europe, or even Asia Minor or Africa, till a spice trade was opened to the remotest part of the Indies, whence it originally came, and where it still rages more cruelly than among us. 3. The *griping of the guts*, which he takes for a disease peculiar to the West Indies, and yearly received from thence: for this he adds, is a quite different disease from the *tormina ventris* of the ancients, and is scarce ever known in the mid-land countries, or far in the North of England.

EXOUCONITÆ, in *Church History*, a kind of Arian heretics, who maintained that the Son of God was made out of nothing: i. e. ἐκ τοῦ οὐκ ὄντος, opposed by Gothofred to be the same with the EXOUCONITÆ; but this opinion is contradicted by the authority of Theodoret.

EXPANSION, in *Metaphysics*, expresses the idea we have of lasting, or preserving distance, i. e. of distance, all the parts whereof exist together.

EXPANSION, in *Physics*, is the dilating, stretching, or spreading out of a body; whether from any external cause as the cause of *rarefaction*, or from an internal cause, as chalkiness. Bodies naturally expand by heat beyond their dimensions when cold, whence their specific gravities are different at the different seasons of the year. Air compressed or condensed, as soon as the compressing or condensing force is removed, expands itself by its elastic power to its former dimensions.

Dr. Halley found by experiment, that water expands itself by one twenty-fifth part of its bulk, when made to boil; but a moderate heat does not induce any sensible *expansion* at all. Mercury, with a very gentle heat, expands itself one seventy-fourth part of its ordinary dimensions.

Spirit of wine with a heat less than that of boiling water expanded itself by one-twelfth part of its bulk, and then began to boil. The most sensible *expansion* of water is in freezing. Mr. Boyle, in his Hist. of Cold, assures us, that ice takes up one-twelfth part more space than water. Dr. Gregory, in his Astron. p. 407, proves, that a globe of ice, of an inch diameter, if it were removed to the distance of a semidiameter of the earth, would expand itself so as to fill all the planetary region as far as, nay, far beyond the sphere of Saturn. See AIR. Solid bodies, as well as fluids, easily expand with heat. See HEAT, PENDULUM, and PYROMETER.

EXPANSUM *Folium*. See FOLIACEUM.

EX PARTE, i. e. *party*, or of *one part*. A *commission ex parte* is that taken out and executed by one part only: where both parties join it is called a *joint commission*. See COMMISSION.

EX PARTE FALIS, in *Law*, a writ that lies for a bailiff or receiver, who having auditors assigned to take his account, cannot obtain of them reasonable allowance, but is cast into prison. The course in this case is to sue this writ out of chancery, directed to the sheriff, to take four mainpernors to bring his body before the barons of the exchequer at a certain day, and to warn the lord to appear at the same time. F. N. B. 129.

EXPECTANT *Fee*, in *Law*, where lands are given to a man and his wife, and the heirs of their bodies; in which sense it differs from *fee simple*, where lands are given to a man and his wife in frank marriage, to hold to them and their heirs.

EXPECTANCY, *estates in*, are of two sorts; one created by act of the parties called a REMAINDER; the other by act of law, called a REVERSION.

EXPECTATION, in the *Doctrine of Chances*, is applied to any contingent event, and is capable of being reduced to the rules of computation. Thus, a sum of money in *expectation*, when a particular event happens, has a determinate value before that event happens; so that if a person is to receive any sum, e. gr. 10*l.* when an event takes place, which has an equal PROBABILITY of happening and failing, the value of the *expectation* is half that sum, or 5*l.* and in all cases, the *expectation* of obtaining any sum is estimated by multiplying the value of the sum expected by the fraction, which represents the probability of obtaining it. The *expectation* of a person who has three chances in five of obtaining 100*l.* is equal to $\frac{3}{5} \times 100$ or 60*l.* and the probability of obtaining 100*l.* in this case is equal to $\frac{3}{5} = \frac{1}{2}$.

If the obtaining of any sum requires the happening of several events that are independent on each other, the value of the *expectation* of that sum is found by multiplying together the several probabilities of happening, and by multiplying the product by the value of the sum expected. E. gr. Suppose, that in order to obtain 90*l.* two events must happen, one of which has three chances to happen and two to fail, and the other has four chances to happen, and five to fail; the value of the *expectation* is $= \frac{3}{5} \times \frac{4}{9} \times 90 = \frac{12}{45} \times 90 = \frac{1080}{405} = 24l.$ for if the first event had actually happened, the value of the *expectation*, depending solely on the second event, would be $\frac{4}{9} \times 90 = 40l.$ and therefore the happening of the first event in the conditions of obtaining an *expectation* worth 40*l.* but the probability of the first happening is $\frac{3}{5}$, and the *expectation* sought for is evidently worth $\frac{3}{5} \times 40 = \frac{2}{5} \times \frac{4}{9} \times 90 = 24l.$ The rule will be the same if an *expectation* depends on the happening of one event and the failing of another; and also on the failing of two events; and on the happening or failing of any number of events that may be assigned. It is here supposed that the events are independent, or that the happening of one neither forwards nor obstructs the happening of the other. But if two events are dependent, i. e. if they are so connected together, as that the probability of either's happening is altered by the happening of the other, the probability of their happening is the product of the probability of the happening of one of them by the probability which the other will have of happening, when the first is considered as having happened; and the same rule will extend to the happening of any assigned number of events: thus, in a heap of thirteen cards of the same colour, the probability of taking out the ace is $= \frac{1}{13}$, and the probability of taking the ace out of another heap of the same number is $= \frac{1}{13}$ and the probability of both these independent events happening will be $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$: but the probability of taking the ace first out of a single heap of thirteen cards is $= \frac{1}{13}$, and that of taking the deus afterwards is $= \frac{1}{13}$ and therefore the probability of both happening is $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$. If a person has several *expectations* on several sums, the value of his *expectation* on the whole is the sum of his *expectations* on the particulars: thus, let one event be such that the probability of obtaining any sum, e. gr. 90*l.* in case it happens, may be $\frac{1}{3}$; in which case the value of the *expectation* is $\frac{1}{3} \times 90 = 54l.$ Let the probability of another event, on which depends a second sum of 60*l.* be $\frac{2}{3}$, and the value of the *expectation* in this case is $\frac{2}{3} \times 90 = 40l.$ and the value of the *expectation* on the whole $54 + 40 = 94l.$ But if a person is to receive 90*l.* once for all for the happening of one or other of the two forementioned events, then, the *expectation* of the first event being worth 54*l.* as before, yet the *expectation* of the second will be different; because this depends on the happening of the first, and takes place only in case the first happens to fail, the probability of which is $\frac{1}{3}$; and on the supposition of its having failed, the *expectation* of the second will be 40*l.* therefore, $\frac{1}{3}$ is the measure of the probability of obtaining an *expectation* worth 40*l.* and consequently the *expectation* will be worth $\frac{1}{3} \times 40 = 16l.$ and the value of the *expectation* on the whole will be $54 + 16 = 70l.$ See the farther illustration and application of these principles and rules in De Moivre's Doctrine of Chances, edit. 3. 1756. See GAMING.

EXPECTATION *of Life*, in the *Doctrine of Life-annuities*, denotes, according to the most obvious sense of the term, that particular number of years which a life of a given age has an equal chance of enjoying, or the time which a person of a given age may justly expect to continue in being. But Mr. Simpson has shewn, that this period does not coincide with what the writers on annuities call the *expectation of life*, except on the supposition of an uniform decrease in the probabilities of life; and Dr. Price adds, that even on this supposition, it does not coincide with what is called the *expectation of life*, in any case of joint lives: for two lives of 40 have an even chance, according to M. De Moivre's hypothesis, (see COMPLEMENT *of life*) of continuing together only $13\frac{3}{4}$ years. According to that hypothesis, the *probability* that a life aged 40 will continue $13\frac{3}{4}$ years, will be expressed by $\frac{32\cdot5}{40}$; and this fraction multiplied by itself is the probability that two lives of this age shall both continue $13\frac{3}{4}$ years; i. e. $\frac{32\cdot5}{40} \times \frac{32\cdot5}{40} = \frac{1056\cdot25}{2116} =$ nearly $\frac{1}{2}$, which represents an even chance; but the *expectation* of two joint lives being (according to the same hypothesis) always a third of the common complement, will be in this case $15\frac{1}{2}$ years. Therefore, *the expectation of life*, or as it may be otherwise called, *the share of life due to a person*, is used to signify the mean continuance of any given single, joint, or surviving lives, according to any given table of observations; or the number of years which, taking them one with another, they actually enjoy, and

may be conſidered as ſure of enjoying; ſo that if 46 perſons are alive, all 40 years of age, and one be ſuppoſed to die every year, according to Mr. De Moivre's hypotheſis, till they are all dead in 46 years, half 46 or 23 will be their *expectation of life*; i. e. the number of years enjoyed by them all will be juſt the ſame as if every one of them had lived 23 years, and then died; ſo that ſuppoſing no intereſt of money, there would be no difference in value between annuities payable for life to every ſingle perſon in ſuch a ſet, and equal annuities payable to another equal ſet of perſons of the ſame common age, ſuppoſed to be all ſure of living juſt 23 years, and no more.

In like manner, the third of 46 years, or 15 years and 4 months, is the *expectation* of two joint lives both 40; and this is alſo the *expectation* of the ſurvivor. The *expectation of life*, in this laſt ſenſe of the terms, coincides with the ſums of the preſent probabilities, that any given ſingle or joint lives ſhall attain to the end of the firſt, ſecond, third, &c. moments, from this time to the end of their poſſible exiſtence; or (in the caſe of ſurvivorſhips) with the ſum of the probabilities, that there ſhall be a ſurvivor at the end of the firſt, ſecond, third, &c. moments, from the preſent time to the end of the poſſible exiſtence of ſurvivorſhip. From theſe principles Dr. Price has ſhewn how to deduce the demonſtration of Mr. De Moivre's rules for finding the *expectations of lives*, which he has omitted: we ſhall here ſubjoin them for the information and amuſement of our mathematical readers.

Let x ſtand for a moment of time, and n be the COMPLEMENT of any aſſigned life; then $\frac{n-x}{n}$, $\frac{n-2x}{n}$, $\frac{n-3x}{n}$, &c. will be the preſent probabilities of its continuing to the end of the firſt, ſecond, third, &c. moments; and $\frac{n-x}{n}$ the PROBABILITY of its continuing to the end of x time; therefore, $\frac{n-x}{n} \times x$ will be the fluxion of the ſum of the probabilities, or of an area repreſenting this ſum, whoſe ordinates are $\frac{n-x}{n}$, and axis x. The fluent of this expreſſion, or $x - \frac{x^2}{2n}$, is the ſum itſelf for the time x; and this, when $x = n$, becomes $\frac{1}{2}n$, the *expectation* of the aſſigned life, or the ſum of all the probabilities juſt mentioned for its whole poſſible duration. Thus, $\frac{n-x}{n} \times \frac{n-x}{n}$, or $\frac{\overline{n-x}^2}{n^2}$, is the probability that two equal joint lives will continue x time, and $\frac{\overline{n-x}^2}{n^2} \times x$ will be the fluxion of the ſum of the probabilities; the fluent of which, or $x - \frac{x^3}{3n^2}$, becomes, when $n = x$, $\frac{n}{3}$, or the *expectation* of two equal joint lives. Again, ſince $\frac{n-x}{n} \times \frac{2x}{n}$ is the probability that there will be a ſurvivor of two equal joint lives at the end of x time, $\frac{n-x}{n} \times \frac{2x}{n} \times x$ will be the fluxion of the ſum of the probabilities; and the fluent, or $\frac{x^2}{n} - \frac{2x^3}{3n^2}$ is, when $x = n$, $\frac{1}{3}n$, or the *expectation* of ſurvivorſhip between two equal lives, which appears to be equal to the *expectation* of their joint continuance. The *expectation* of two unequal joint lives found in the ſame way is $\frac{m}{2} - \frac{m^3}{6n^2}$, m being the complement of the oldeſt life, and n the complement of the youngeſt. The whole *expectation* of ſurvivorſhip is $\frac{n}{2} - \frac{m}{2} + \frac{m^3}{3n^2}$; and the *expectation* of ſurvivorſhip of the oldeſt will be to that of the youngeſt as $\frac{m^2}{6n}$ to $\frac{n}{2} - \frac{m}{2} + \frac{m^3}{6n}$.

From the definition already given of the *expectation of life*, it follows, that if in a ſociety limited to a fixed number of members, a 28th part of its members dies annually, 28 would appear to be their common *expectation of life* at the time they entered; and if it were found in any town or diſtrict, where the number of births and burials are equal, that a 20th or 30th part of the inhabitants die annually, it would appear that 20 or 30 was the *expectation* of a child juſt born in that town or diſtrict.

Having a table of obſervations, ſhewing the number that die annually at all ages out of a given number alive at thoſe ages, it is eaſy to find the *expectation* for all ſingle lives by the following rule: divide the ſum of all the living in the table at the age whoſe *expectation* is required, and at all greater ages, by the number in the table of the living at that age, and ſubtract half unity from the quotient, the remainder will be the *expectation* required.

The reaſon of this ſubtraction may be underſtood by conceiving the recruit neceſſary to ſupply the waſte of every year to be made always at the end of the year, ſo that the dividend ought to be the medium between the number living at the beginning and the end of the year; and therefore it ſhould be taken leſs than the ſum of the living in the table at and above the given age by half the number that die in the year; but as the diviſor is to the dividend as unit to the quotient, the ſubtraction here directed will have the ſame effect as the afore-mentioned diminution. This rule may be illuſtrated by taking the ſum of all the living at 20 and upwards in *Tab.* I. and dividing it by 360, the number living at that age, and the quotient leſs half unity, will be nearly 28.9 the *expectation* of 20 in *Tab.* II.

TABLE I.

Shewing the Probability of the Duration of Life in London, deduced by Mr. Simpſon from Obſervations on the Bills of Mortality in London for Ten Years, from 1728 to 1737.

75	5½	5½	8	7	6½	7
80	4	4½	5	5	5½	6

Dr. Price has applied his reasoning on this subject to the solution of a curious question in political arithmetic, or to determine the number of inhabitants in any place from a table of observations, or the bills of MORTALITY for that place, on the supposition that the yearly births and burials are equal. For this purpose, find by the table the *expectation* of an infant just born; and this, multiplied by the number of yearly births, will be the number of inhabitants.

It appears from Tab. I. that though an infant just born in London has not an equal chance (the probability being 7755) of living 3 years, his *expectation* is 20 years. The medium of the yearly births in London for 20 years from 1759 to 1778 was 15,510, multiply 15,510 by 20, and the product, viz. 314,200 will be the number of inhabitants in London, according to the bills, if the yearly burials were no more than equal to the births, or there were no supply of inhabitants from the country: but, during the forementioned period, the burials were at an average 22,956, and exceeded the christenings 7,246, which exactly gives the annual supply from other parts; and if each of these have an *expectation* of 30 years, or they are all of the age of 18 or 20, when they remove to London, multiply 30 by 7,246, and the product, viz. 217,380 must be added to 314,200, and the sum, or 531,580 gives the number of inhabitants, supposing that the bills are perfect: but this is certainly not the case; the number both of births and burials is for many obvious reasons too small. If the annual defects in births and burials were 6000, then 20 × 6000 = 120,000 must be added to 531,580, and the whole number of inhabitants would be 651,580. If the burials are deficient only two-thirds of this number or 4000, and the births the whole of it, 20 × 6000 must be added to 314,200, on account of the defects in the births; and the excess of the burials being then only 5246, 30 × 5246 = 157,380 must be added on this account; and the number of inhabitants will be 591,580. If the *expectation of life* in London be diminished to 18 or 17, this number must be reduced; and Dr. Price concludes on the whole, from a great variety of observations, that 591,580 is nearest to the true number of inhabitants; though Dr. Brakenridge, allowing 6 to a house, makes the number of inhabitants in London 751,800: but the allowance of 6 to a house is certainly too large, as Dr. Price has shewn in a variety of instances from actual surveys; and he observes, that though 5 persons to a house may not be much too small an allowance for London, it is too large for England in general. If the number of houses in England and Wales be reckoned a million, the number of people will be 4½ millions, allowing 4½ to a house, and 5 millions, allowing 5 to a house. In the year 1690, the number of houses, according to Dr. Davenant, was 1,319,215; at the Restoration it was 1,230,000; in 1759, 980,482; in 1768, 980,6921; so that between the Restoration and Revolution the people of England increased above 300,000: since the year 1690, they have decreased near a million and a half. The number of houses in Ireland in 1754 was 395,439; in 1767, it was 424,646; and allowing 4½ to a house, the number of people in Ireland will be 1,908,207; and if a million and a half are supposed in Scotland, the number of people in Great Britain and Ireland will be about 8 millions. De Moivre's Doctrine of Chances applied to the Valuation of Annuities, p. 288, &c. Simpson's Select Exercises, p. 253, &c. and particularly Dr. Price's Observations on Reversionary payments, vol. i. p. 168. &c. p. 364, &c. 374, &c. or Phil. Trans. vol lix. p. 89. See LIFE-*annuities*, MORTALITY, SURVIVORSHIP.

EXPECTATIVE, in the *Canon Law*, a hope founded on a promise of obtaining the next benefice that shall become vacant, or a right to the reversion of the next. See BENEFICE.

EXPECTATIVE *canon*. See CANON.

EXPECTATIVE *grace*, *Gratiæ* EXPECTATIVÆ, called also *præventiæ*, were bulls frequently given by the popes or kings for future benefices. The bishops were exceedingly mortified with them, because they encroached on their privileges; besides, that such *expectatives* are odious, as they induce people to wish for the death of others.

The use of *expectatives* is very ancient, though it was not near so frequent in the first ages as afterwards. Originally they were no more than simple requests made on the part of kings or popes, which the bishops consented to with the more willingness, as they only presented to them persons fit to serve the church; but the frequent exercise of this privilege made it at length be deemed a matter of obligation and necessity.

The council of Trent annulled all *expectatives*; but the canons relating thereto were never admitted in France, where the right of conferring *expectative* graces is looked on as one of the regalia.

EXPECTORANTS, in *Pharmacy*, are medicines that promote EXPECTORATION.

As all substances which promote excretion do not operate in the same manner, since some render the matter moveable, and dispose it for evacuation; others open the emunctories, that it may be separated from the juices; and others stimulate the vessels and ducts to an excretory motion; so *expectorants* operate in the same variety: *ways*; for if the humour secreted be thin and acrid, and the pores of the glands from which it is to be thrown be too much constricted, these medicines are to be given to promote expectoration, which relax, soften, and widen the passages, obtund the acrimony of the humours, and coagulate the too thin and fluid parts of them. To this purpose liquorice-root, spermaceti, saffron, mallows, red poppies, oil of almonds, and the styrax pill, may be given; but when a large quantity of thick and viscid matter is lodged in the bronchia of the lungs, and impedes respiration, then some stimulus to respiration becomes necessary, and expectoration must be assisted by substances which can resolve the tough and viscid matter. For this purpose decoctions of scabious and the other pectoral herbs with the terra foliata tartari, solutions of crabs eyes, and antimoniated nitre, are very proper. The nervous coats of the bronchia are also stimulated to an excretory motion by a certain acrid, subtile, and oleous principle, found in gum ammoniac and benjamin, and the like stimulating gums.

The roots of chamæpanse, and Florentine orris also, and all the preparations of sulphur, serve excellently to this purpose; and where a yet stronger stimulus is required, as in a pituitous asthma, oxymel of squills, and the spiritus ammoniacus, which is prepared with gum ammoniacum and crystals of copper, are found remedies of very great power. Great caution is necessary in the exhibition of *expectorants*, and the practitioner who gives the common medicines, known by that name at random, and without informing himself thoroughly of the nature of the case, is likely to do great mischief instead of good by them. In coughs of the moist and chronical kind, as also in a pituitous asthma, in which large quantities of phlegm

phlegm fall into the bronchia of the lungs, sweet substances, linctuses, and oily medicines, weaken the stomach, whose strength and tone are already too much impaired, diminish the appetite, digestion, and chylification, and not only promote the generation of more excrementitious matter, and the increase of the disease, but also dispose the patient to a cachexy, or to oedematous tumors, or a dropsy. In these cases, it is therefore much more proper to use balsamic pectorals, and such as are grateful to the stomach. Hoffm. Med. Ration. Syst.

Expectorants ought to be cautiously used in a phthisis, in spittings of blood, and in dry coughs, difficulties of breathing, and violent pains in the breast, which rather arise from a congestion of blood than from matter to be expectorated; and *expectorants*, whether of the softening or of the stimulating kind, must certainly add to the congestion of the blood and humours, rather than to the relief of the patient.

In pleurisies and peripneumonies, *expectorants* are to be very cautiously used in the beginning, lest by their means the inflammatory stagnation of the blood should be increased: but when these disorders are upon the decline, and the greater part of the inflammatory matter is discussed, then they are very properly and commodiously used to draw the viscid and concocted matter out of the pulmonary canals.

EXPECTORATION, of *ex*, *out*, and *pectus*, *breast*, the act of evacuating or bringing up phlegm or other matters out of the trachea, lungs, &c. by coughing, hawking, spitting, &c. See COUGH.

Expectoration eases the lungs of the viscid or putrid matters which obstructs their vessels, and straitens the breast.

EXPEDITATION, in the *Forest-laws*, signifies a cutting out the balls of a dog's fore-feet for the preservation of the king's game.

Every one that keeps any great dog, not *expeditated*, forfeits three shillings and four-pence to the king. In mastiffs, not the ball of the feet, but the three claws are to be cut to the skin. Inſtit. part iv. p. 308. *Nullus Dominicos canes abbatis & monachorum expeditari cogat.* Chart. Hen. III. *Et ſin quieti de expeditamentis canum.* Ex. Mag. Rot. Pip. de ann. 9 Ed. II.

This *expeditation* was to be performed once in every three years, and was done to every man's dog who lived near the foreſt, and even the dogs of the foreſters themſelves.

EXPEDITION, the march of an army to ſome diſtant place, with a view of hoſtilities.

Such were the *expeditions* of Cyrus againſt Xerxes, and of Bacchus and Alexander from the Indies.

Expeditions for the recovery of the Holy Land were called CROISADES.

EXPENCES, in *Book-keeping*. See BOOK *of expences*.

EXPENDITORS, in *Law*, are the perſons appointed by commiſſioners of ſewers, to pay, diſburſe, or expend the money collected by the tax for the repairs of ſewers, &c. when paid into their hands by the collectors on the reparations, amendments, and reformations ordered by the commiſſioners; for which they are to render accounts when required for that purpoſe.

Theſe officers are mentioned in the ſtatute 37 H. VIII. cap. 11. and other ſtatutes. The Reward who ſupervifes the repair of the banks and water-courſes in Romney-Marſh, is likewiſe called the *expenditor*.

EXPENSIS *militum levandis*, was a writ anciently directed to the ſheriff, for levying allowance for the knights of parliament. See PARLIAMENT, and REPRESENTATIVE.

EXPENSIS *militum non levandis, &c.* in *Law*, an ancient writ to prohibit the ſheriff from levying any allowance for knights of the ſhire upon thoſe that hold lands in ancient *demeſne*. Reg. Orig. 261.

EXPERIENCE, a kind of knowledge acquired by long uſe, without any teacher.

Experience conſiſts in the ideas of things we have ſeen or read, which the judgment has reflected on, to form for itſelf a rule or method.

Authors make three kinds of *experience*: the firſt is the ſimple uſes of the external ſenſes, whereby we perceive the phenomena of natural things, without any direct attention thereto, or making any application thereof.

The ſecond is, when we premeditatedly and deſignedly make trials of various things, or obſerve thoſe done by others, attending cloſely to all effects and circumſtances.

The third is that preceded by a foreknowledge, or at leaſt an apprehenſion of the event, and determines whether the apprehenſion were true or falſe; which two latter kinds, eſpecially the third, are of great ſervice in philoſophy.

EXPERIMENT, in *Philoſophy*, a trial of the effect or reſult of certain applications and motions of natural bodies, in order to diſcover ſomething of the laws and relations thereof, or to aſcertain ſome phenomenon, or its cauſe. The ſchoolmen define *experiment*, a compariſon of ſeveral things before obſerved by the ſenſes, and retained in the memory in ſome one ſimilar convenient inſtance.

The nature of *experiment*, therefore, according to them, conſiſts in comparing ſeveral things by one act; whence they diſtinguiſh two things in every *experiment*, the one *materiale*, viz. the ſeveral ideas remembered; the other *formale*, viz. the comparing of theſe ideas in the mind.

This will be illuſtrated by an example: a phyſician gives a quantity of rhubarb to ten ſeveral perſons, and remembers each of them. Now, coming afterwards to compare the ſeveral remembrances together, and finding the effect of the exhibition of rhubarb to be the ſame in all, viz. a purging; this is an *experiment* of rhubarb.

The making of *experiments* is grown into a kind of formed art; and we now abound in ſyſtems of *experiments*, under the denomination of *ſtories of experimental philoſophy*. Sturmius has made a curious collection of the principal diſcoveries and *experiments* of the laſt age, under the title of *collegium experimentale*. Dr. Defaguliers has alſo publiſhed a comprehenſive and uſeful courſe of *experimental* philoſophy. The chemiſts chooſe to call their *experiments*, by way of diſtinction or eminence, *proceſſes* or *operations*.

EXPERIMENTAL *Philoſophy*, by the Greeks called ἐμπειρικὴ, or ἐμπειρικὸν, is that which proceeds on *experiments*, or which deduces the laws of nature, and the properties or powers of bodies, and their actions upon each other, from ſenſible *experiments* and obſervations.

Experiments are of the utmoſt importance in philoſophy, and the great advantage the modern phyſics have above the ancient, is chiefly owing to this; that we have a great many more *experiments*, and that we make more uſe of the *experiments* we have.

Their way of philoſophizing was [illegible] in with the cauſe of things, and argue to the [illegible] phenomena; ours, on the contrary, proceeds [illegible] and obſervations alone.

Lord Bacon firſt [illegible] way for the new philoſophy, by ſetting on foot the making of *experiments*. His method has been proſecuted with [illegible] emulation by the Academy del Cimento, the Royal Society, Royal Academy at Paris; and by Mr. Boyle, Sir Iſaac Newton, and many others.

In effect, *experiments* within the laſt century, are come into ſuch a vogue, that nothing will paſs in philoſophy but what is founded on, or confirmed by, *experiment*; ſo that the new philoſophy is almoſt altogether *experimental*. Indeed, the ancients, whatever we commonly ſay to the contrary, ſeem to have thought as well of the *experimental* way as the moderns. Plato miſſes no occaſion of ſpeaking of the advantages of the πειρατικὴ; and as to Ariſtotle, his Hiſtory of Animals may bear witneſs for him. Democritus's great buſineſs was to make *experiments*; and even Epicurus himſelf owes part of his glory to the ſame cauſe. Plato calls it, in reſpect to its ſubject, τὸ ἀισθητὸν, *ſubtility of ſenſe*.

Yet there are ſome, even among the learned, who conceive of *experiments* in a different manner. Dr. Keil allows, that philoſophy has received very conſiderable advantages from the makers of *experiments*; but he complains of their diſingenuity, in too often wreſting and diſtorting their *experiments* and obſervations to favour ſome darling theories they had eſpouſed; but this is not all; M. Hartſoeker, in his Recueil de pluſieurs Pieces de Phyſique, undertakes to ſhew, they who employ themſelves in the making of *experiments* are not properly philoſophers, but, as it were, the labourers or operators of philoſophers, who work under them, and for them, furniſhing them with materials to build their ſyſtems and hypotheſes upon.

The learned M. Dacier, in the beginning of his diſcourſe on Plato, at the head of his tranſlation of the works of that philoſopher, deals ſtill more ſeverely with the makers of *experiments*. He breaks out with a ſort of indignation at a tribe of idly curious people, whoſe ſole employ conſiſts in making *experiments* on the gravity of the air, the equilibrium of fluids, the loadſtone, &c. and yet arrogate to themſelves the noble title of philoſophers. See PHILOSOPHY and PHYSICS. See alſo ANALYSIS and SYNTHESIS.

EXPERIMENTUM *Crucis*, denotes a capital, leading, or deciſive experiment; thus called, either, becauſe like a croſs or direction-poſt, placed in the meeting of ſeveral roads, it guides and directs men to the true knowledge of the nature of the thing they are enquiring after; or, as it is a kind of torture, whereby the nature of the thing is, as it were, extorted by violence.

EXPIATION, the act of ſuffering the puniſhments adjudged to a man's crimes, and thus paying off, or diſcharging the debt or guilt; and it is figuratively applied

to the pardon procured for the sins of the penitent by the interposition and death of Christ.

The Romanists hold, that souls after death are sent to PURGATORY to *expiate* or atone for their sins.

EXPIATION is also applied to sacrifices offered to the Deity, to implore his mercy and forgiveness.

EXPIATION, *the feast of*, among the Jews, called by our translators the *day of atonement*, was held on the tenth day of Tisri, or the seventh month of the Jewish year, answering to part of our September and October. It was instituted by God himself, Levit. xxiii. 27, &c. On that day the high-priest, the figure or type of Jesus Christ, entered into the most holy place, and confessed his sins; and, after several ceremonies, made an atonement for all the people to wash them from their sins. Lev. chap. xvi. See SCAPE-*goat*.

EXPIATION, among the *Heathens*, denoted a purification used for effacing or abolishing a crime, averting any calamity; and on a thousand other occasions, as purifying towns, temples, and sacred places, and armies, before and after battle.

It was practised with divers ceremonies: the most usual was ablution.

Expiations were performed for whole cities as well as particular persons. After the young Horatius had been absolved by the people from the murder of his sister, he was further purified by several *expiations* prescribed by the laws of the pontifices for involuntary murders. Halicarnass.

EXPILATION, from *expilo, I rob*, in the *Civil Law*, the act of withdrawing or diverting something belonging to an inheritance, before any body had declared himself heir thereof.

This made a peculiar species of theft; for there could not properly be a theft in taking a thing not possessed by any body, or before the inheritance was accepted.

For this reason the Roman legislature introduced the action of *expilata* for the punishment of this crime.

Beside this meaning, it was used in a more special manner, to signify a robbery committed by night; whence an *expilator* was looked upon as a greater criminal than a common thief.

The *expilators* were so called from their robbing and stripping people of their clothes.

EXPIRATION, in *Medicine*, that motion in an animal whereby the air inspired into the lungs is expelled or thrown out of the same, and the cavity of the breast contracted.

Respiration consists of two alternate motions or actions of the lungs, corresponding to those of a pair of bellows: *inspiration*, whereby the air is drawn in; and *expiration*, whereby it is driven out again.

By the means of this alteration, the circulation of the blood, and the motion of the heart, are maintained.

EXPIRATION is also used figuratively, for the end of a term of time granted, agreed on, or adjudged.

EXPLEES, in *Law*, the rents or profits of an estate, &c. See EXPLEES.

EXPLICATIVE *Proposition*, in *Logic*. See COMPLEX *proposition*.

EXPLICIT, in the *Schools*, something clear, distinct, formal, and unfolded.

The will or intention is said to be *explicit* when it is fully explained in proper terms; and *implicit*, when it is only to be learnt by deductions and consequences.

The Jews had not all an *explicit* knowledge of Jesus Christ, but they had at least an implicit one.

Such a testator has declared his will *explicitly*, i. e. in formal terms; there is no need to have recourse to explications.

EXPLOSION, from *explodo, I drive away with noise*, in *Physics*, the act of a thing which drives another away out of the place it before possessed.

The term is chiefly used for the going off of gunpowder, and the expulsion of the ball, shot, or the like consequent thereon.

Hence, *explosion* comes likewise to be figuratively used to express such sudden actions of bodies as have some resemblance to these; e. gr. those which ferment with violence, immediately upon their mixture, and occasion a crackling sound.

EXPOLITION, in *Rhetoric*, a figure whereby we explain the same thing in different phrases and expressions, in order to shew it more fully.

Expolition was the favourite figure of Balzac.

EXPONAS *Penditioni*. See VENDITIONI.

EXPONENT, from *expono, I express*, in *Arithmetic*. *Exponent of a power* denotes the number which expresses the degree of the power, or which shews how often a given power is to be divided by its root before it be brought down to unity.

Thus, the *exponent* or index of a square number is 2; of a cube, 3; the square being a power of the second degree; the cube, of a third, &c.

Exponents are commonly written above, and somewhat towards the right-hand of the number or quantity whose power they express. Thus, a^5, a^5, signifies the fifth power of 3, and of a. See POWER.

EXPONENT is also used in *Arithmetic*, in the same sense with index or logarithm.

Thus a series of numbers in arithmetical progression being placed under another series in geometrical progression, are called the *exponents*, *indices*, or *logarithms*, thereof. E. gr. in the two progressions.

Geom. 1, 2, 4, 8, 16, 32, 64, 128, 256, 512

Arith. 0, 1, 2, 3, 4, 5, 6, 7, 8, 9

0 is the *exponent*, index, or logarithm, of the first term 1; 5 that of the sixth, 32, &c.

Hence, unity is to the *exponent* of a power as the logarithm of the root to the logarithm of its power; consequently, the logarithm of the power is had by multiplying the logarithm of the root by its *exponent*; and the logarithm of the root is had by dividing the logarithm of the power by its *exponent*.

EXPONENT *of a ratio*, is the quotient arising upon dividing the antecedent by the consequent.

Thus, in the ratio 3 to 2, the *exponent* is $1\frac{1}{2}$, and the *exponent* of the ratio 2 to 3 is $\frac{2}{3}$. See RATIO.

Hence, 1. If the consequent be unity, the antecedent is the *exponent* of the ratio. Thus, e. gr. the *exponent* of the ratio 4 to 1, is 4; and again, the *exponent* of a ratio is to unity as the antecedent to the consequent.

2. Since, in a rational ratio, the *exponent* of a ratio is had by dividing a rational number by another rational; the *exponent* of a rational ratio is a rational number.

EXPONENTIAL *Calculus*, *Calculus* EXPONENTIALIS, is a method of differencing *exponential* quantities, and of summing up the differences of *exponentials*. See CALCULUS.

EXPONENTIAL *curve*, is that which is defined by an *exponential equation*.

Exponential curves partake both of the nature of algebraic and transcendental ones; of the former, because they consist of a finite number of terms, though those terms themselves are indeterminate; and of the latter, because they cannot be algebraically constructed, or represented by an algebraic equation. Thus, $a^y = x^a$ is the equation of an algebraic curve; $y = a^x$ is the equation of an *exponential* curve: this equation $y = a^x$ denotes that any ordinate y is to a constant ordinate assumed equal to 1, as a constant quantity a raised to a power whose exponent expresses the ratio of the abscisa x to the line equal to 1 is to the line taken for unit or 1, raised to the same exponent. Let b represent the line $= 1$, and the equation $y = a^{\frac{x}{b}}$, (since $y : b :: a^{\frac{x}{b}} : b^{\frac{x}{b}}$) will become $\frac{y}{b} = \frac{a^{\frac{x}{b}}}{b^{\frac{x}{b}}}$. Note, $y = a^x$ is the equation of the LOGARITHMIC curve.

EXPONENTIAL *equation*, is that wherein there is an *exponential* quantity. See EQUATION, &c.

EXPONENTIAL *quantity*, is a power whose *exponent* is an indeterminate, or variable quantity.

Exponential quantities are of several degrees and orders: when the *exponent* is a simple indeterminate quantity, it is called an *exponential of the first*, or *lowest degree*.

When the *exponent* itself is an *exponential* of the first degree, then the quantity is an *exponential of the second degree*. Thus, z^y is an *exponential* of the first degree, because the quantity y is a simple flowing quantity; but z^x is an *exponential* quantity of the second degree; because y^x is an *exponential* of the first degree; so also, z^{y^x} is an *exponential* of the third degree, the *exponent* y^x being one of the second: and universally, the *exponential* quantity of any degree has for its *exponent*, the *exponential* quantity of the degree next preceding it. See Bernoulli Oper. tom. i. p. 182, &c.

EXPORTATION, in *Commerce*, the act of sending commodities out of one country into another.

Exportation is a part of foreign COMMERCE, distinguished by the appellation *active*, or *selling part*, in opposition to *importation*, which is called the *passive*, or *buying part*.

It is observed as a general maxim, that commerce, when active, must produce a flow of riches, the balance being received in money; whereas, if it be passive, treasures will be exhausted, as the BALANCE of *trade* must continually be made good out of the remaining coin. Hence plenty of money in any place implies, that the quantity of goods exported *far* exceeds that of goods imported;

and wherever money is scarce, it *must* be concluded, that greater quantities of goods have been imported than exported. See EXCHANGE.

The merchandizes yearly exported from England are immense. The principal articles are corn, cattle, cloth, iron, lead, tin, leather, coal, hops, flax, hemp, hats, malt-liquors, fish, watches, ribbands, &c.

Wool, fuller's earth, &c. are contraband goods, i. e. they are prohibited to be exported. For the duties of *exportation*, see DUTY.

EXPOSING, the act of setting a thing to public view.

In the Romish church, the facrament is faid to be *expofed* when it is fhewn in public, uncovered, on feftival days, and during the time of plenary indulgences.

EXPOSING is alfo ufed with a farther latitude; thus, we fay, it is prohibited to *expofe* falfe and clipped money.

Such a houfe ftands very high, and has a delicious profpect; but it is *expofed* to all the four winds. Such a city being on the frontiers, and not fortified, is *expofed* to the infults of every party of forces.

EXPOSING *of children*, a barbarous cuftom practifed by moft of the ancients, excepting the Thebans, who had an exprefs law to the contrary, whereby it was made capital to expofe children, ordaining, at the fame time, that fuch as were not in a condition to educate them fhould bring them to the magiftrates, in order to be brought up at the public expence. Pot. Archæol. Græc. tom. ii. p. 333.

Among the other Greeks, when a child was born, it was laid on the ground; and if the father defigned to educate his child, he immediately took it up; but if he forbore to do this, the child was carried away, and *expofed*. Pitifc. Lex. Ant. in voc. *Expofitio*.

The Lacedæmonians, indeed, had a different cuftom; for, with them, all new-born children were brought before certain tryers, who were fome of the graveft men in their own tribe, by whom the infants were carefully viewed; and if they were found luftly and well-favoured, they gave orders for their education, and allotted a certain proportion of land for their maintenance; but if weakly, or deformed, they ordered them to be caft into a deep cavern in the earth, near the mountain Taygetus, as thinking it neither for the good of the children themfelves, nor for the public intereft, that defective children fhould be brought up.

Many perfons *expofed* their children only becaufe they were not in a condition to educate them, having no intention that they fhould perifh. It was the unhappy fate of daughters efpecially to be thus treated, as requiring more charges to educate and fettle them in the world than fons.

The parents frequently tied jewels and rings to the children they *expofed*, or any other thing whereby they might afterwards difcover them, if Providence took care for their fafety. Another defign, in adorning thefe infants, was either to encourage fuch as found them to nourifh and educate them, if alive; or to give them human burial, if dead.

The places where it was ufual to *expofe* children were fuch as people frequented moft. This was done in order that they might be found, and taken up by compaffionate perfons who were in circumftances to be at the expence of their education. With this intention the Egyptians and Romans chofe the banks of rivers, and the Greeks the highways.

EXPOSITION, the act of *expofing*. See EXPOSING.

EXPOSITION is likewife applied to the interpretation or explication of an author, or paffage therein. See EXEGESIS.

EXPOSITION, *expofitio*, in *Rhetoric*, is fometimes ufed for *divifion*. See DIVISION; and fee alfo EXERGASIA.

EXPOSITION, in *Gardening*. See EXPOSURE.

EXPOSITOR, or EXPOSITORY, a title which fome writers have given to a leffer kind of dictionaries or vocabularies, ferving to expound or explain the meaning of the obfcure or difficult words of a language.

It is alfo ufed in the fame fenfe with COMMENTARY and PARAPHRASE.

EX POST FACTO, in *Law*, denotes fomething done after another thing that was committed before. An eftate granted may be made good by matter *ex poft facto*, that was not fo at firft, by election, &c.

EXPOSTULATION, *expoftulatio*, in *Rhetoric*, a complaint addreffed to a perfon from whom we have received fome injury. It varies according to circumftances.

EXPOSURE, or EXPOSITION, in *Gardening*, the afpect or fituation of a garden wall, building, or the like, with refpect to the fun, wind, &c.

There are four regular kinds of *expofures*, viz. *eaft*, *weft*, *north*, and *fouth*; but it muft be obferved, that among gardeners thefe terms fignify juft the contrary to what they do among geographers.

The gardeners, in effect, do not give the names *eaft*, *weft*, &c. to the places where the fun is, but to thofe whereon he fhines; and they conſider the manner wherein he fhines, whether as to the whole garden, or fome of its fides.

If they find, that the fun at his rifing, and during the firft half of the day, continues to fhine on one fide of a garden or wall, they call that an *eaftern expofure*, or *eaft wall*, &c. and if the fun begin to fhine later, or end fooner, it is not a proper *eaftern expofure*.

For the fame reafon, they call the *weft* the fide the fun fhines on in the latter half of the day; i. e. from noon to night; and accordingly, the *fouth*, or *fouthern expofure*, is the place whereon he fhines from about nine o'clock in the morning till night; or which, in the general, he fhines longeft on in the whole day; and the part he fhines leaft on is the *north*, or *northern expofures*, at what hour forever it begin or end, being ufually from eleven o'clock to one.

The *eaftern* and *fouthern expofures* are, by common conſent of all gardeners, the two principal, and have a conſiderable advantage above the reſt. A *weft expofure* is not much amifs; at leaft, it is better than a northern one, which is the worſt of all: each has its inconveniencies.

The eaſtern, commencing differently at different ſeaſons of the year, and ending about noon, ſubjects the trees, &c. to the N. E. winds, which wither the leaves and new ſhoots, blow down the fruit, &c. beſide that it has little benefit of rains, which come moſtly from the weſt. Yet does the reverend Mr. Laurence judge the eaſt better than the weſt-wall for all kinds of fruit; not that it has more hours of ſun, or that there are any peculiar virtues in the eaſtern rays, but becauſe the early rays of the ſun do ſooner take off the cold chilly dews of the night.

M. Gentil recommends the *eaſtern expoſure* as beſt for all kinds of peaches; adding, that they [illegible] footſtil, grow bigger, are better [illegible] taſte, than in any other: but Mr. Lawrence [illegible] the rule to the early and [illegible] be rather choices a *ſouthern expoſure*, which is beſt for all late fruits, [illegible] the influences of the ſun is ſtrongeſt, and continue [illegible] moſt.

The *weſtern*, [illegible] half an hour paſt eleven till ſun-ſet, is [illegible] inferior than an *eaſtern* one by eight or ten days; but it has this advantage, that it receives little damage from the froſts, which melt before the ſun comes to ſhine upon the fruit, and fall off like dew, without doing any prejudice; ſo that it may bear apricots, peaches, pears, and plums; but it is incommoded with north-weſt winds in the ſpring, as alſo with the autumnal winds, which blow down a great quantity of fruit.

According to Mr. Miller, the beſt aſpect or *expoſure* for walls in England is the point to the eaſtward of the ſouth; becauſe thoſe will enjoy the benefit of the morning ſun, and be leſs expoſed to the weſt and ſouth-weſt winds, which are very injurious to fruits in England, than thoſe walls which are erected due ſouth; the next beſt *expoſure* is due ſouth, and the next to that ſouth-eaſt, which is preferable to the ſouth-weſt. Other walls, however, may be planted with fruit-trees that ſuit their ſeveral *expoſures*.

The *northern expoſure* is the leaſt favourable of any in England, as having very little benefit from the ſun even in the height of ſummer, therefore can be but of little uſe, whatever may have been advanced to the contrary. For although many ſorts of fruit trees will thrive and produce fruit in ſuch poſitions, yet ſuch fruit can be of little worth, ſince they are deprived of the kindly warmth of the ſun to correct their crude juices, and render them well-taſted and wholeſome. It is therefore to little purpoſe to plant fruit-trees againſt ſuch walls, except it be for fruit intended for baking, &c. in which caſe the fire will ripen and render thoſe juices wholeſome which could not be performed while growing.

In ſuch ſituations, morelli cherries for preſerving may be planted, and white and red currants to come late, after thoſe which were more expoſed to the ſun are gone; and if the ſoil be warm and dry, ſome ſorts of ſummer pears will do tolerably well on ſuch an *expoſure*, and will continue longer in eating than if they were expoſed to the ſun. But winter pears ſhould by no means be planted in ſuch an aſpect, as has been practiſed by many ignorant perſons, if we find that the beſt ſouth walls in ſome bad years are barely warm enough to ripen them. Duke cherries planted againſt walls expoſed to the north will ripen much later in the ſeaſon; and if the ſoil be warm, will be well flavoured, and continue a month later than others. Miller.

The *ſouthern expoſure*, accounted from about nine till four, is recommended for peaches, pears, grapes, and plums.

EXPRESS,

EXPRESS, fomething that is preciſe in formal terms, or for fome particular deſign. I told him as much in *expreſs* terms; he gave me a commiſſion *expreſs*; he had *expreſs* orders; a courier was diſpatched *expreſs*.

We alſo ſay, fomewhat abuſively, to ſend an *expreſs*, meaning a COURIER.

EXPRESSED *Oils*, are ſuch as are procured from bodies only by preſſing; as the oils of olives, almonds, and the like. See OIL.

EXPRESSED *ſpecies*. See SPECIES.

EXPRESSION, in *Algebra*, denotes the value of a quantity expreſſed or repreſented under an algebraic form: thus if $x = \sqrt{a^2 + b^2}$, and a and b are known, the value of x is known. See EQUATION.

EXPRESSION, in *Medicine, Chemiſtry*, &c. the act of *expreſſing* or extracting the juices or oils of plants, fruits, or other matters, by ſqueezing, wringing, or preſſing them in a preſs. After having let the herbs infuſe a due time, their juice muſt be drawn by *expreſſion* in a linen cloth, or by a preſs.

EXPRESSION, in *Muſic*, denotes the performing of a piece of melody, or a ſingle paſſage, with that energy and feeling which the poetry or paſſion to be impreſſed upon the hearer requires.

EXPRESSION, in *Oratory*, denotes the manner of delivering or conveying a man's ideas to another.

EXPRESSION is more particularly uſed for the ELOCUTION, diction, and choice of words in a diſcourſe.

It is not enough that a poet or orator have fine thoughts, he muſt likewiſe have a happy *expreſſion*. Defects in the *expreſſion* ordinarily ariſe from defects in the imagination: abundance of the beauties of the ancient writers are annexed either to *expreſſions* which are peculiar to their language; or to relations, which, not being ſo familiar to us as to them, do not give us the ſame pleaſure.

EXPRESSION, *diverſifying of*, in *Rhetoric*. See DIVERSIFYING.

EXPRESSION, in *Painting*, denotes a natural and lively repreſentation of the ſubject, or of the ſeveral objects intended to be ſhewn.

The *expreſſion* conſiſts principally in repreſenting the human body and all its parts in the action ſuitable to them; in exhibiting in the face the ſeveral paſſions proper to the figures, and obſerving the motions they impreſs on the other external parts.

The term *expreſſion* is ordinarily confounded with that of *paſſion*; but they differ in this, that *expreſſion* is a general term, implying a repreſentation of an object, agreeably to its nature and character, and the uſe or office it is to have in the work; whereas paſſion, in painting, denotes a motion of the body, accompanied with certain diſpoſitions or airs of the face, which mark an agitation in the ſoul. So that every paſſion is an *expreſſion*, but not every *expreſſion* a paſſion.

EXPRESSION *in painting, laws or rules of*. *Expreſſion*, we have ſaid, is a repreſentation of things according to their character, and may be conſidered either with reſpect to the ſubject in general, or to the paſſions peculiar thereto.

I. With regard to the ſubject, it is to be obſerved,

1. That all the parts of the compoſition are to be tranſformed or reduced to the character of the ſubject, ſo that they may conſpire to impreſs the ſame ſentiment, paſſion, or idea: thus, e. gr. in a repreſentation of joy and peace, every thing is to appear calm and agreeable; of war, turbulent and full of terror, &c.

2. In order to this, if any circumſtance occur in hiſtory or deſcription that would invert or take from the idea, it muſt be ſuppreſſed, unleſs eſſential to the ſubject.

3. To this end the hiſtory or fable is to be well ſtudied in the authors who deſcribe it, in order to conceive its nature and character truly, and impreſs it ſtrongly on the imagination, that it may be diffuſed and carried through all the parts of the ſubject.

4. A liberty is to be taken of chooſing favourable incidents, in order to diverſify the *expreſſion*, provided they be not contrary to the principal image of the ſubject, or the truth of hiſtory.

5. The harmony of the *tout enſemble* muſt be particularly regarded, both with reſpect to the actions and the light and colour.

6. The modes and cuſtoms are to be obſerved, and every thing made conformable to time, place, and quality.

7. The three unities of time, place, and action, ought to be obſerved; that is, nothing ſhould be repreſented in the ſame picture but what paſſes at the ſame time, and may be ſeen at the ſame view.

II. With regard to the particular paſſions and affections of the ſubject: the rules are, 1. That the paſſions of brutes are few and ſimple, and have almoſt all an immediate reſpect, either to ſelf-preſervation, or the propagation of the kind; but in men there is ſcope for greater variety, and accordingly more marks and *expreſſions* thereof.

2. Children not having the uſe of reaſon, act much after the manner of brutes, and *expreſs* the motions of their paſſions directly, and without fear or diſguiſe.

3. Though the paſſions of the ſoul may be *expreſſed* by the actions of the body, it is in the face they are principally ſhewn, and particularly in the turn of the eye, and the motions of the eye-brows.

4. There are two ways of lifting up the eye-brows, the one at the middle, which likewiſe draws up the corners of the mouth, and argues pleaſant motions: the other at the point next the noſe, which draws up the middle of the mouth, and is the effect of grief and ſadneſs.

5. The paſſions are all reducible to joy and ſadneſs; each of which is either ſimple or mixed and paſſionate.

6. Simple joy cauſes a dilatation of all the parts; the eye-brows riſe in the middle, the eyes half-open, and ſmiling, the pupil ſparkling and moiſt, the noſtrils a little open, the cheeks full, the corners of the mouth drawn a little upwards, the lips red, the complexion lively, and the forehead ſerene.

7. Paſſionate joy, proceeding from love, ſhews the forehead ſmooth and even, the eye-brows a little elevated on the ſide the pupil is turned to, the eyes ſparkling and open, the head inclined towards the object, the air of the face ſmiling, and the complexion ruddy. That proceeding from deſire ſhews itſelf by the body, the arms being extended towards the object, in uncertain and unquiet motions.

8. Simple ſadneſs is *expreſſed* by the body being caſt down, the head carelеſſly hanging aſide, the forehead wrinkled, the eye-brows raiſed to the midſt of the forehead, the eyes half ſhut, the mouth a little open, the corners downwards, the under-lip pointing and drawn back, the noſtrils ſwelled and drawn downwards. Sadneſs mixed with fear cauſes the parts to contract and palpitate, the members to tremble and fold up, the viſage to be pale and livid, the point of the noſtrils elevated, the pupil in the middle of the eye, the mouth opened at the ſides, and the under-lip drawn back. In that mixed with anger the motions are more violent, the parts all agitated, the muſcles ſwelled, the pupil wild and ſparkling, the point of the eye-brows fixed towards the noſe, the noſtrils open, the lips big, and preſſed down, the corners of the mouth a little open and foaming, the veins ſwelled, and the hair erect. That with deſpair reſembles the laſt, only it is more exceſſive and diſordered.

9. The hand has a great ſhare in the *expreſſion* of our ſentiments and paſſions: the raiſing of the hands conjoined towards heaven, *expreſſes* devotion; wringing the hands, grief; throwing them towards heaven, admiration; fainting and dejected hands, amazement and deſpair; holding the hand, tillneſs; holding the fingers indented, muſing; holding forth the hands together, yielding and ſubmiſſion; lifting up the hand and eye to heaven, calling God to witneſs; waving the hand from us, prohibition; extending the right hand to any one, pity, peace, and ſafety; ſcratching the head, thoughtfulneſs and care; laying the hand on the heart, ſolemn affirmation; holding up the thumb, approbation; laying the fore-finger on the mouth, bidding ſilence; giving with the finger and thumb, *parce date*, or *giving ſparingly*; and the fore-finger put forth, the reſt contracted, *monſtrare, & dicere, to point at, and ſay; hic eſt, this is he*.

10. The ſex of the figure is to be regarded; and man, as he is of a more vigorous and reſolute nature, is to appear in all his actions freer and bolder than women, who are to be more reſerved and tender.

11. So alſo the age, the different ſtages whereof incline to different motions both of body and mind.

12. The condition, or honours, with which a perſon is inveſted, render their actions more reſerved, and their motions more grave; contrary to the populace, who obſerve little conduct or reſtraint, giving themſelves for the moſt part up to their paſſions, whence their external motions become rude and diſorderly.

Laſtly, in *ſpirits* we muſt retrench all thoſe corruptible things which ſerve only for the preſervation of life, as veins, arteries, &c. only retaining what may ſerve for the form and beauty of the body. In angels, particularly, as being ſymbolical figures, we are to mark out their offices and virtues, without any draught of ſenſual paſſions, only appropriating their characters to their functions of power, activity, and contemplation.

EXPROBATION, *Exprobatio*, in *Rhetoric*, is the reproaching of a perſon with ingratitude, and unmindfulneſs of ſome particular benefit conferred upon him.

EXPULSION, the act of driving a man by force out of a city, community, or the like.

EXPULSION is also used in *Medicine*, for the act of driving out a foreign body with violence from the place it was in.

The uterus has the chief office in the *expulsion* of the fœtus: if the *expulsion* of the fœtus happen very soon after conception, it is called a *false birth*. See FŒTUS and DELIVERY.

EXPURGATION, in *Astronomy*, is used by some authors for that state or action of the sun, wherein, after having been eclipsed and hid by the interposition of the moon, it begins to appear again.

Later astronomers call this EMERSION, not *expurgation*.

EXQUIMA, in *Zoology*, the name of a species of monkey common on the coast of Guinea. The hair on its back is of a reddish brown, and looks as if it had been singed or burnt, and resembles a rusty iron colour: among this there are a number of small white spots; its belly and chin are wholly white, and it has a very beautiful beard of a snow-white, composed of hair of two fingers length, and always lying as neatly and regularly as if it were combed. When this creature is provoked, it draws back its lips, and, shewing all its teeth, shuts its jaws very nimbly, and chatters remarkably loud. It is very nimble, and leaps surprisingly: it feeds on the fruits it finds in the woods. *Ray*.

There is also another species of this creature in Guinea, of the size of the former, and of a blackish brown on the greatest part of the body, but of a bluish grey on the belly, and the lower half of its tail is of a sort of tawney colour; its mouth and nose are blue, and its cheeks adorned with a multitude of yellow hairs clustered together like those of a goat's beard. Its legs and feet are wholly black, it is a sprightly animal, and skips and plays like the other. Besides these, there is also a third, of the *exquima* kind, smaller than the others, and of a mixt colour of brown, yellow, and grey: this has a long tail, a small head, and no beard.

EXSIBILANTES, in *Antiquity*, a kind of hissers, who, in the theatre and other public auditories, used to make a noise with their feet, and even sometimes beat the seats with bastons.

EXSICCATION, formed of *ex* and *siccus*, *dry*, in *Chemistry*, &c. the act of drying up or evaporating the moisture of a thing.

EXSORS *Particulæ*. See PARTICULA.

EXSUCCATIO, a word used by some *Chirurgical Writers*, to express an ECCHYMOSIS, or suggillation.

EXSUFFLATION, a ceremony observed in baptism, by which the candidate was supposed to renounce the devil. See BAPTISM.

EXTANT, something that still subsists, or is in being.

It is but part of the History of Livy, of the writings of Cicero, Cæsar, &c. that are *extant*, the rest are lost. We have nothing *extant*, of Socrates, though he wrote a great deal.

EXTACY, *Ecstasy*, a rapture, or removal of the mind out of its natural state and situation; or a transport, whereby a person is hurried out of himself, and the office of his senses is suspended. See ENTHUSIASM.

EXTASY, in *Medicine*, is considered as a disease, near akin to a catalepsy, only differing from it in this, that the cataleptic patient has no perception of what passes in his paroxysm, nor any remembrance thereof when it is over; whereas the *extatic* is taken up with a very lively idea or imagination, which he remembers afterwards.

In an *extasy*, there must be an unusual tension of the fibres of the sensory, as in most deliriums, &c.

EXTEMPORANEOUS *Prescription*. See PRESCRIPTION.

EXTEND, in the *Manege*. To *extend a horse*, is an expression used by some to import the same with making a horse go large. See LARGE.

EXTEND, in *Law*. See EXTENDING.

EXTENDENDA *Terra*. See TERRA.

EXTENDENTIUM *Interior*, in *Anatomy*, a name given by Spigelius and others to a muscle of the wrist, called by Albinus, *minoris externus*, and by Winslow and others, CUBITALIS *externus*. See ULNARIS *exterior*.

EXTENDI *Facias*, in *Law*, a writ of extent, whereby the value of lands is commanded to be made and levied, &c. Reg. Orig.

EXTENDING, in a *Legal Sense*, signifies the valuing of lands and tenements of one bound by statute, &c. and who hath forfeited his bond at such an indifferent rate, as that by the yearly rent the obligator may in time be fully paid his debt. See EXTENT.

EXTENSION, in *Physics*, that whereby a thing is constituted long, broad, or thick, &c. or that property of bodies whereby they occupy a certain portion of space.

Extension is usually described as consisting in the situation of parts beyond parts; with which some authors cavil, as holding, that we can conceive absolute *extension* without any relation to parts.

If a man consider the distance between two bodies abstractedly, and without any regard to bodies which may fill that interval, it is called *space*; and when he considers the distance between the extremes of a solid body, it is called *extension*.

Extension is frequently confounded with quantity and magnitude; and, for what we can perceive, without much harm; the thing signified by them all appearing to be the same: unless we admit a distinction made by some authors, that the *extension* of a body is something more absolute, and its quantity and magnitude more respective, or implying a nearer relation to much and little. See QUANTITY, MAGNITUDE, MASS, and MATTER.

The infinite divisibility of *extension* has been a famous question in all ages. It is not easy to reconcile the doctrine of mathematicians on this head with the tenets of some philosophers. They who hold that all *extension* and magnitude are compounded of a certain *minima sectilia*; and that a line, for instance, cannot increase or decrease but by certain indivisible increments or decrements only, must consistently with themselves affirm, that all lines are commensurable to each other, contrary to the tenth book of Euclid, who demonstrates, that the diagonal of a square is commensurable to its side. But if all lines were composed of certain indivisible elements, it is plain one of those elements must be the common measure of the diagonal and the side. This is a gordian knot which none of the philosophers have yet thought fit to untie.

Bishop Berkeley observes, that the infinite divisibility of finite *extension*, though it is not expressly laid down either as an axiom or theorem in the elements of geometry, yet is throughout the same every where supposed, and thought to have so inseparable and essential a connection with the principles and demonstrations in geometry, that mathematicians never admit the least doubt, or make the least question of it. And it is from hence the source from whence do spring all those amazing geometrical paradoxes, which have such a direct repugnancy to the plain common sense of mankind, and are admitted with so much reluctance by those who have not yet debauched by learning; that is, by the perverting the natural ocasions of all that nice and extreme subtilty which renders the study of mathematics so difficult and tedious. Hence, says he, if we can make it appear, that no finite *extension* contains innumerable parts, or is infinitely divisible, it follows, that we shall at once clear the science of geometry from a great number of difficulties and contradictions which have ever been esteemed a reproach to human reason, and withal make the attainment thereof a business of much less time and pains than it hitherto hath been.

Every particular finite *extension*, which may possibly be the object of our thought, is an idea existing only in the mind, and consequently each part thereof must be perceived. If therefore I cannot perceive innumerable parts in any finite *extension* that I consider, it is certain they are not contained in it; but it is evident, that I cannot distinguish innumerable parts in any particular line, surface, or solid, which I either perceive by sense, or figure to myself in my mind; wherefore, I conclude they are not contained in it. Nothing can be plainer to me, than that the *extension* I have in view are no other than my own ideas; and it is no less plain, that I cannot resolve any one of my ideas into an infinite number of other ideas; that is, that they are not infinitely divisible. If by an infinite *extension* be meant something distinct from a finite idea, I declare I do not know what that is, and so cannot affirm or deny any thing of it. But if the terms *extension*, parts, and the like, are taken in any sense conceivable; that is, for ideas; then to say a finite quantity or *extension* consists of parts infinite in number, is to manifest a contradiction, that every one at first sight acknowledges it to be so. New Theory of Vision, § 54, 55. Analyst. § 31.

On the other hand, it is observable by an eminent mathematician, that geometricians are under no necessity of supposing that a finite quantity or *extension* consists of parts infinite in number, or that there are any more parts in a given magnitude than they can conceive or express: it is sufficient that it may be conceived to be divided into a number of parts equal to any given or proposed number; and this is all that is supposed in strict geometry concerning the divisibility of magnitude. It is true, that the number of parts into which a given magnitude may be conceived to be divided, is not to be fixed or limited, because no given number is so great but a greater than it may be conceived and assigned; but there is not therefore any necessity for supposing that number infinite: and if some may have drawn very absurde consequences from such suppositions, they are not to be imputed to geometry. See Maclaurin's Treatise of Fluxions, art. 290.

Dr. Reid, a late writer, in his Inquiry into the Human Mind, on the principles of common ſenſe, endeavours to obviate the difficulties ſuggeſted by Berkeley, by overturning the ſyſtem of ideas eſtabliſhed by Mr. Locke. According to his theory, it is abſurd to deduce from ſenſation the firſt origin of our notions of external exiſtences, of ſpace, motion, and *extenſion*. and all the primary qualities of bodies; they have, he ſays, no reſemblance to any ſenſation, or to any operation of our minds, and therefore they cannot be ideas either of ſenſation or of reflection; nor can he conceive how *extenſion* or any image of *extenſion* can be in an unextended and indiviſible ſubject like the human mind.

EXTENSOR *of fractured limbs, in Surgery*. When the fractured bones maintain their natural ſituation, the ſurgeon has nothing to do but to apply a proper bandage to keep them in it; but when the fractured parts recede from one another, ſome degree of *extenſion* is neceſſary, which muſt always be ſuited to the diſtortion of the limb. The greater diſtance there is between the extremities of the divided parts of the bone, ſo much the ſhorter will the limb become from the natural contraction of the muſcles, and the *extenſion* muſt be proportionably the greater; but in theſe caſes every thing is to be done tenderly, and with great care. 1. The patient is to be kept very firm and ſteady; the poſture of the body muſt be, in this operation, different, according to the different circumſtances of the caſe; ſometimes ſitting, and ſometimes lying, are the moſt proper. 2. An aſſiſtant muſt ſupport the limb with his hands, both above and below the fractured part. 3. The perſon who holds the lower part of the limb muſt extend it ſtrongly and equally, till the fractured bone can be replaced; but when the ſurgeon is called at ſome diſtance of time from the accident, and a tumor and inflammation are come on, it is beſt in ſuch caſe to defer the *extenſion* of the parts till theſe ſymptoms are removed, by letting blood, ſoftening the bowels, giving the patient large quantities of aqueous fluids, and preſcribing the proper internal remedies for ſtopping inflammations, and fomenting the parts with warm diſcutient decoctions. Theſe applications will uſually ſucceed as well as to take down the inflammation in twenty-four hours, in ſuch a manner, that the *extenſion* of the limb may be ſafely attempted; but when they do not take place ſo ſuddenly, they are to be repeated till they have the deſired effect; and where the common fomentations fail, the following has often very great and happy ſucceſs: take two or three handfuls of ſcordium, and boil them for about a quarter of an hour in a pint of water, with ſix ounces of rectified ſpirit of wine; afterwards mix with it an ounce of common ſalt, and half an ounce of ſaltpetre, and apply this to the inflamed fractured limb. To make the proper *extenſion* of a limb, the ſurgeon muſt, while it is kept in its proper length by two aſſiſtants, direct it with his hands, ſometimes a little one way, ſometimes another, putting it into different poſitions, as the nature of the caſe ſhall require, till the parts have recovered their natural ſituation. This will be known by the remiſſion or abſence of pain, and by obſerving that the fractured limb is of the ſame length with the ſound one; and if theſe ſigns of ſucceſs in the operation are wanting, there is great reaſon to ſuppoſe that the operation is as yet ineffectual, and the *extenſion* is to be repeated or continued till the bones are evenly and properly replaced. Heiſter's Surg. p. 108.

EXTENSOR, in *Anatomy*, a name common to ſeveral muſcles, ſerving to extend or ſtretch out the parts, and particularly the hands and feet; ſuch are the

EXTENSOR *carpi ulnaris*, called alſo *cubitæus internus*, a muſcle, which, coming from the internal protuberance of the humerus, and paſſing tendinous under the ligamentum annulare, is inſerted into the upper part of the bone of the metacarpium, which anſwers to the little finger: this, and the ulnaris flexor moving together, draw the hand ſideways towards the ULNA. See *Tab. Anat. (Muſcl.) fig.* 1. *n.* 38. and *fig.* 6. *n.* 18.

EXTENSOR *carpi radialis*, called alſo *cubitæus externus*, and *brevior*, is really two diſtinct muſcles. The firſt ariſes from above the external protuberance of the humerus; and the ſecond from the lowermoſt part of the external protuberance. They both lie along the external part of the radius, and, paſſing under the annular ligament, one is inſerted into the bone of the metacarpus that ſuſtains the fore-finger, and the other to that which ſuſtains the middle-finger: theſe two extend the wriſt. See *Tab. Anat. (Muſcl.) fig.* 1. *n.* 29. and *fig.* 6. *n.* 19.

EXTENSOR *communis digitorum manus*, ariſes from the external protuberance of the humerus, and at the wriſt divides into three flat tendons, which paſs under the annular ligament, to be inſerted into all the bones of the fore, middle, and ring-finger. See *Tab. Anat. (Muſcl.) fig.* 1. *n.* 36. *fig.* 6. *n.* 20.

It very much reſembles the perforatus and perforans, and lies on the outſide of the fore-arm, between the ulnaris externus and radialis externus. It is fixed above, by a tendinous extremity to the poſterior and lower part of the external or great condyle of the os humeri; and, by a tendinous adheſion on each ſide, to the ulnaris and radialis externus. It has likewiſe ſometimes a ſmall inſertion in the radius: it is divided into four muſcles, like the perforatus and perforans, and four long ſlender ſmall tendons. Three of theſe tendons paſs through the common external annular ligament of the carpus; and the fourth, which goes to the little-finger, and which has ſometimes its fleſhy portion diſtinct from the reſt, paſſes through a particular ring of the ſame ligament. Afterwards, theſe four tendons ſeparate as they go to the fingers, and in their paſſage communicate with each other, by oblique tendinous ſeries, chiefly near the heads of the metacarpal bones. The tendons of the middle and little-finger are ſometimes double, and yet communicate with the reſt.

Each tendon, having reached the baſis of the firſt phalanx, is ſlightly inſerted therein by ſome lateral expanſions, fixed in each ſide of the baſis; from thence it advances to the head of the ſame phalanx, where it is divided into two flat portions, which, at the articulation of the firſt phalanx with the ſecond, leave ſome diſtance between them. About the head of the ſecond phalanx they unite again, and are fixed in the convex ſide near the baſis in the third phalanx. The ſeparation of the two portions is in ſome fort rhomboidal, and each portion is ſtrengthened by a common tendon of the lumbricales and interoſſei, and in the ſmall ſpaces between them are ſmall tendinous frænæ, more or leſs tranſverſe. Winſlow's Anatomy, p. 199.

EXTENSOR *primi internodii pollicis*, ariſes from the upper and external part of the ulna, and paſſing obliquely over the tendon of the *radialis externus*, is inſerted near the ſecond joint of the thumb.

EXTENSOR *ſecundi internodii pollicis*, ariſes from the upper and internal part of the radius, and is inſerted into the upper part of the ſecond bone of the thumb.

EXTENSOR *tertii internodii pollicis*, ariſes from the ulna, a little below the firſt *extenſor*, and is inſerted into the third bone of the thumb.

EXTENSOR *indicis*, comes from the middle and external part of the ulna, and paſſing under the annular ligament is inſerted into the third bone of the fore-finger, where it joins the *extenſor communis*.

EXTENSOR *auricularis digiti*, ariſes from the external protuberance of the humerus, and from the upper part of the ulna, and paſſing under the annular ligament, is inſerted into the third bone of the little finger. See *Tab. Anat. (Muſcl.) fig.* 1. *n.* 37. and *fig.* 6. *n.* 17.

EXTENSOR *digitorum pedis longus*, is a muſcle derived from the fore-part of the upper epiphyſis of the tibia, and growing tendinous about the middle thereof, it runs in four tendons under the annular ligament, to the third bone of every toe, except the pollex. See *Tab. Anat. (Muſcl.) fig.* 2. *n.* 45. *fig.* 1. *n.* 64.

According to Winſlow, it is a long muſcle, fleſhy in its upper part, but tendinous in the lower, lying between the tibialis anticus and peroneus maximus. It is fixed above by fleſhy fibres in the outſide of the head of the tibia, and inſide of the head of the fibula, in the upper part of the interoſſeous ligament, through three-fourths of the length of the fibula, and through the ſame ſpace in the tendinous ſeptum belonging to the anterior angle of that bone. It ſeems to mix ſome fibres on each ſide with the two firſt peronei and tibialis anticus, and is very cloſely united with the peroneus maximus. It contracts in breadth a little above the annular ligament, and in paſſing through it is divided into three tendons, the firſt of which is afterwards again divided into two. Theſe four tendons are inſerted along the upper or convex ſide of the boſſes of the four ſmall toes. Winſlow's Anatomy, p. 222.

EXTENSOR *digitorum pedis brevis*, comes from the exterior and fore-part of the calcaneum, and goes to the ſecond joint of the toes. See *Tab. Anat. (Muſcl.) fig.* 1. *n.* 73.

It is fixed in the upper and outer ſide of the anterior apophyſis of the aſtragalus, and in the adjoining part of the upper ſide of that bone. Thence it runs obliquely inwards, and is divided into four fleſhy portions, which terminate in four tendons. The firſt is inſerted in the upper part of the firſt phalanx of the great toe; and the other three, joining with thoſe of the *extenſor longus*, are inſerted along the convex ſides of all the phalanges of the three following toes. When there is a fifth tendon, which ſometimes happens, it goes in the ſame manner to the little toe. Winſlow's Anatomy, p. 223.

EXTENSOR *indicis proprius*, a ſmall long muſcle, with a long ſlender tendon, lying a little obliquely on the lower and outer-half of the fore-arm, between the ulna and the

fore-finger. It is fixed by its fleshy body a little higher than the lowest third part of the outside of the ulna, below the insertion of the *extensor pollicis*; and it has likewise a small adhesion to the interosseous ligament. From thence it runs down, ending in a distinct tendon, without any communications, which having passed through the annular ligament of the *extensor communis*, afterwards joins that tendon which goes to the index. Winslow's Anatomy, p. 200.

EXTENSOR *minimi digiti proprius*, a collateral or auxiliary muscle of the *extensor communis*, of which it appears almost always to be more or less a portion. It is fixed along the superior external half of the ulna, from whence its long small tendon runs down in company with the fourth tendon of the *extensor communis*, all the way to the little-finger, where it joins, and is inserted with it. Sometimes this muscle is wanting; in which case the *extensor communis* sends a double, and sometimes a treble tendon to the little finger. Winslow's Anatomy, p. 200.

EXTENSORES *pollicis manus*, two very distinct muscles, the first or longest of which is sometimes more, sometimes less, and sometimes altogether divided into two; in which case these muscles are three in number. They are situated obliquely between the ulna and the convex side of the thumb.

The *extensor primus* is a long muscle, more or less double, and is fixed above by fleshy fibres, first to the outside of the ulna, near its upper extremity, below the anconeus minor and insertion of the ulnaris externus; next to the interosseous ligament, under the supinator brevis; and lastly, to the middle part of the outside of the radius. From thence it runs down, and passes obliquely over the lower part of the radius, and tendons of the supinator longus and radialis externus; and being gradually divided, it terminates in two long flat tendons, more or less subdivided, which pass together under a particular annular ligament, being only parted by septa or sheaths belonging to that ligament. The first of these two principal tendons is inserted in the edge of the basis of the first phalanx, near the large transverse ligament of the carpus: when this tendon is subdivided, the other portion of it is fixed in that bone of the carpus which sustains the thumb. The other principal tendon, which often belongs to a muscle entirely distinct from the former, is fixed in the convex side of the basis of the second phalanx, where it joins the tendon of the *extensor secundus*. On account of these different insertions of the two tendons, this muscle is by some authors described as two.

The *extensor secundus* is shorter than the first; it is fixed to the ulna below the former, and above the insertion of the *extensor indicis proprius*, and likewise to the neighbouring part of the interosseous ligament. From thence it runs down obliquely on the middle part of the radius, where it has also a small adhesion; after this it passes through the small channel in the styloide apophysis of the radius through the annular ligament belonging to the tendons of the radialis externus, and over these tendons, being parted from them by a small ligamentary septum. It is inserted in the convex part of the third phalanx near its base, having, as it passes over the second phalanx, joined the second or collateral tendon of the first *extensor*, more or less. Winslow's Anatomy, p. 196.

EXTENSOR *pollicis pedis longus*, rises large and fleshy from the fore-part of the fibula, a little below its upper procefs; whence, passing under the annular ligament, it is inserted into the upper part of the second bone of the great toe. See *Tab. Anat. (Myol.) fig.* 1. *n.* 71.

It is fixed to the inside of the fibula, near the interosseous ligament, from the neck down to the lowest quarter of that bone; to the interosseous ligament through the same space, and a little to the lower extremity of the tibia near the fibula. It there ends in a considerable tendon, which passing through a distinct ring of the common annular ligament, and then through its membranous vagina, is inserted in the basis of the first phalanx of the great toe, and continued up to the second. Winslow's Anatomy, p. 221.

EXTENSOR *pollicis pedis brevis*, springs fleshy from the fore-part of the os calcis, and, after a short belly, is contracted into a slender tendon; which, running obliquely over the upper part of the foot, is inserted into the second bone of the great toe. See *Tab. Anat. (Myol.) fig.* 1. *n.* 75. *fig.* 2. *n.* 51.

EXTENSOR *proprius auricularis*, in *Anatomy*, a name given by Albinus, and some other late authors, to one of the muscles of the hand, called by Cowper and others the *extensor minimi digiti*.

EXTENSOR *tarsi*, in *Anatomy*, a name given by Douglas and some others, to a muscle more generally known by the name of the *peronæus*. See PERONÆUS.

EXTENT, in *Law*, sometimes denotes a writ or commission to the sheriff for the valuing of lands and tenements; sometimes the act of the sheriff upon this writ; and sometimes the estimate or valuation of lands *ex parte regis*; which, when taken at the utmost value or *extent*, furnish our extended, or rack-rents. Phillips.

EXTENUATION, the act of diminishing or lessening the bulk or substance of a thing, especially of the human body. Fevers, agues, long abstinence, &c. occasion great *extenuations* or emaciations.

EXTENUATION is also a figure in *Rhetoric*, opposite to the hyperbole. The Greeks call it τάπωσις.

EXTERIOR *Polygon, Vide* See the substantives.

EXTERMINATION, formed of *ex* and *terminus*, *boundary*, the act of *extirpating*, or totally destroying a people, race, family, &c.

The Jews have been *exterminated* out of Portugal, the Moors out of Spain, the Albigenses out of France, &c. Philip the Fair of France, to be revenged on the Knights Templars, took a resolution in 1307 to *exterminate* them.

EXTERMINATION, or EXTERMINATING, in *Algebra*, is used for taking away. Thus algebraists speak of *exterminating* surds, fractions, and unknown quantities out of equations. See Maclaur. Algebr. part 1. chap. 12. where we have some general theorems for the *exterminating* unknown quantities in given equations.

EXTERNAL, or EXTERIOR, a term of relation, applied to the surface or outside of a body; or that part which appears or presents itself to the eye, touch, &c.

To which body it is opposed to *internal*, or *interior*.

External medicines are also called *local medicines*, and *topics*. The senses are divided into *external*, which are those whereby we perceive ideas from the perception of *external* objects; as seeing, hearing, &c. and internal. See SENSE.

EXTERNAL is also used to express something that is without, outside a man, or that is not in his mind, and particularly in his mind, by the sixth sense, by *external objects*, &c.

The existence of *external bodies*, i. e. of bodies and objects out of the mind, is a thing which has been greatly controverted by Dr. Berkeley, and others. See EXISTENCE, BODY, and QUALITY.

EXTERNAL *Angles*, are the angles of any right lined figure formed without it, when all the sides are severally produced. These are all, taken together, equal to four right angles. Particularly, in a triangle, the *external* angle is equal to both the internal and opposite ones. See TRIANGLE.

EXTERNAL *Denomination*, *Ear*, *Meatus*, *Plate*. See the substantives.

EXTERNUS *auris*, in *Anatomy*, a small muscle coming from the side of the meatus auditorius, to the short process of the malleus; serving to draw the handle thereof downwards, and so to relax the membrana tympani. See EAR.

EXTERNUS *Brachialis*, *Cubitæus*. See the substantives.

EXTERNUS *Dorsalis*, a name given by Douglas to one of the muscles of the ear, called by Cowper and others *tensor auris*, and by Albinus *externus mallei*.

EXTERNUS *Mallei*, in *Anatomy*, a name given by Albinus to one of the muscles of the ear, called by others *obliquus auris*, and *musculus externus auris*.

EXTERNUS *Gastrocnemius*, *Humeri*. See the substantives.

EXTERNUS *Occipitis*, *Pterygoideus*, *Poplæi*, *Rectus Capitis*. See the substantives.

EXTINCTION, *the act of extinguishing*, that is, of putting out, or destroying, a fire, flame, or light.

The Antiperistasists account for the *extinction* of fire from the principle of contrariety: thus, by wet, water puts out fire; because the qualities of water are contrary to those of fire, the one being cold and moist, and the other hot and dry. But how far this will go, may appear hereafter, that fire is extinguished by hot water as readily as cold; as was shewn by oil, earth, &c.

Some of the moderns allot two more plausible causes of *extinction*; viz. *obstruction*; as when the next, immediate food of the flame is dispersed and blown off by too forcible a wind; and *suffocation*, when it is so compressed, that its free motion cannot be maintained; as happens upon throwing water, &c. thereon. Various preparations and engines have been contrived for extinguishing accidental fires. See FIRE.

Boerhaave denies, that there is properly any such thing as extinguishing of fire: it is a body *sui generis*, of an immutable nature; and we can no more *extinguish* or destroy it, than we can create it.

EXTINCTION, in *Chemistry* and *Pharmacy*, is when a metal, mineral, or the like body, after having been heated red-hot in the fire, is plunged in some fluid; either to soften or temper its acrimony, as iron in rose-water; or to com-

communicate its virtue to the liquor, as iron or steel to common water; or, lastly, to give it a temper, as in the *extinction* of steel in water, or some other preparation.

EXTINGUISHMENT. In *Law*, is used for a *consolidation*. Thus, if a man, having a yearly rent due to him out of my lands, afterwards purchase the same lands; both the property and rent becoming consolidated, or united in one possessor, the rent is said to be *extinguished*.

So, where a man has a lease for years, and afterwards buys the property, there is a *consolidation* of the property, and an *extinguishment* of the lease.

So also, if there be lord mesne, and tenant, and the lord purchase the tenancy, the mesnalty is *extinct*.

Likewise by purchasing of lands wherein a person hath common appendant, the common is *extinguished*. Cro. F. 504. A release of common in one acre, is an *extinguishment* of the whole common. Shower's Rep. 350. And where a person hath common of pasture, if he incloses any part of the land, all the common is extinct. 1 Brownl. 174. If a man hath a high-way appendant to land, and afterwards purchaseth the land wherein the high way is, the way is extinct: though it is held, that a way of necessity to a market or church, or to arable land, is not so *extinguished*.

EXTINGUISHMENT *of a copyhold* takes place on any act of the copyholder's, which denotes his intention to hold no longer of his lord, and amounts to a determination of his will: As if a copyholder in fee accepts a lease for years of the same land from the lord, or accepts an assignment of a lease made to another from the lessee, his copyhold is extinct.

EXTINGUISHMENT *of debt* happens in a variety of cases. Thus if a creditor accept a higher security than he had before, or accepts a bond for a legacy, the first debt or legacy are hereby *extinguished*.

EXTINGUISHMENT *of liberties*, in *Law*. If liberties and franchises granted by the king, come again to the crown, they shall not be *extinguished*: but it is otherwise in the king's grants of felon's goods, waifs, strays, wrecks, &c. 9 Rep. 25.

EXTINGUISHMENT *of services*. If the lord purchases or accepts any part of the tenancy, out of which an entire service is to be paid, the service becomes thereby extinct; unless it be for the public good or homage and fealty, which are not subject to *extinguishment*.

EXTINGUISHMENT *of sins*. See EXTINGUISHMENT.

EXTIRPATION, formed of *ex*, and *stirps*, *root*, the act of pulling up, or destroying a thing to the very roots.

Among the prayers of the Romish jubilee, there is one for the *extirpation* of heresy.

EXTIRPATION is also used, in *Surgery*, for cutting off any part entirely; as a wen, &c. or the eating it away, as a wart, &c. by corrosive medicines. See AMPUTATION, and CORROSION.

EXTIRPATIONE, in *Law*, a judicial writ, either before or after *judgment*, that lies against a person, who when a verdict is found against him for land, &c. doth maliciously overthrow any house, or *extirpate* any trees upon it. Reg. Jud. 13. p. 56.

EXTISPEX, formed of *exta*, and *spicere*, of *spicio*, *I view*, *consider*, in *Antiquity*, an officer who viewed and examined the entrails of victims; in order to draw presages from them as to futurity.

This kind of divination, called *extispicium*, was much in vogue throughout Greece, where there were two families, the Jamidæ and Clytiadæ, consecrated, or set apart, peculiarly for it.

It appears to have been very ancient, and was probably derived from the ancients. Vitruvius, cap. 4. lib. 1. gives us following plausible account of its origin. He says that the ancients inspected the lives of those animals which frequented the places where they intended to build or encamp; and if they commonly found that the liver, to which they attributed sanguification, was injured, they concluded that the waters and nourishment collected near such places were not wholesome.

In Italy, the first *extispices* were the Horrurians; among whom, likewise, the art was in great repute. Lucan gives us a fine description of one of these operations in his first book.

EXTORTION, in *Law*, an illegal manner of wresting any thing from a man, either by force, menace, or authority.

If an officer, by terrifying another, on pretence of his office, takes more than his ordinary fees, or does, he commits, and is indictable for *extortion*.

So the exacting of unlawful usury, winning by unlawful game, and, in fine, all taking of more than is justly due by colour or pretence of right, as excessive tolls in millers, excessive prices of ale, bread, victuals, wares, &c come under *extortion*.

Crompton says, that wrong done by any man, is properly a trespass, but excessive wrong is *extortion*; which is most properly applicable to sheriffs, mayors, bailiffs, and other officers, who, by colour of their office, greatly oppress and wrong the king's subjects, by taking excessive rewards, or fees, for executing their office.

EXTRA-*cestellary fees*. See SPORADES.

EXTRA-*judicial*, something done out of the proper court, or the ordinary course of law. As when judgment is given in a cause, or case, not depending in that court where such judgment is given, or wherein the judge has no jurisdiction.

EXTRA-*mundane space*, is the infinite, empty, void space, which is by some supposed to be extended beyond the bounds of the universe, and consequently in which there is really nothing at all.

EXTRA-*parochial*, a place out of the bounds of any parish; or privileged and freed from the duties of a parish.

EXTRACT, EXTRACTUM, in *Pharmacy*, the purest and finest part of a vegetable, or other body, separated from the coarser, by dissolution and digestion with a proper menstruum; and afterwards reduced into a thick, moist consistence by distillation, or evaporation of the humidity of the menstruum.

Mr. Geoffroy, who well knew the value of this form of medicine, attempted to improve upon the common method of making *extracts*, and succeeded greatly to his wishes; the consequence of which was his presenting to the Academy of Sciences at Paris his method of doing it.

The hint was taken from a method used by the count Lagarais, to make what he called his essential salts of plants; which were only dry *extracts*, prepared by powdering the substance, and then keeping it in continual motion for six or seven hours in common water, by means of a chocolate mill, turned by a large horizontal wheel. After the water had subsided for an hour, the remaining liquor was poured off, and evaporated over a balneum Mariæ, or in the sun, and a volatile dry *extract* prepared. The method of this process made it impracticable in large quantities of medicines; and Mr. Geoffroy removed the great difficulties that attended it, by proving from repeated experiments, that boiling or infusing the substances in hot water, extracted from them all that was got out by the long motion of the mill; as was instanced in the most familiar manner, in the common way of making tea and coffee, which were found to impregnate water with as much of their virtue by the methods of infusion and decoction, as by ever so long an operation in the count's method. The expence of making *extracts* of this kind cannot but be greater than that of managing the same medicines any other way: but the ease of taking, and the small dose, cannot but sufficiently recommend them; and according to Mr. Geoffroy's method, the sick may prepare them for themselves. Mr. Geoffroy gives some examples of his success in these preparations: he took a dram of sena in powder, and pouring on it a quantity of hot water, left it in infusion twenty-four hours; then filtering the infusion, he evaporated the liquor in balneo Mariæ, to the consistence of a thin syrup, and spreading this over the bottoms of two or three broad earthen plates, that it might dry regularly, he evaporated the remaining humidity over the same balneum; and procured twenty-four grains of a dry *extract*, wholly resembling count Lagarais's salts, and operating in the same manner, and with the same virtues, as a dram of sena, whether taken in powder or bolus, or dissolved in any fluids, in any of which forms it had nothing of the nauseous taste of sena. See Mem. Acad. Scienc. Par. 1728.

Extracts are prepared from a variety of different drugs; as the barks, gentian, jalap, opium, &c. See EXTRACTUM *Cathartinum*.

EXTRACT, in *Matters of Literature*, denotes a short abridgment of a book or paper, or of some of the matters therein. The journals, memoirs, bibliotheques, ephemerides, and other monthly reviews, or quarterly accounts of the affairs of learning, consist principally of *extracts* of the most material passages, doctrines, &c. found in the several books published in that time.

EXTRACT *ab exitibus*. See RESTITUTIONE *extractæ*.

EXTRACTA *curiæ*, in our *Old Writers*, the issues or profits of holding a court, arising from the customary fees, &c.

EXTRACTION, in *Pharmacy* and *Chemistry*, an operation, whereby essences, tinctures, &c. are drawn from natural bodies.

Some will have *extraction* to signify any solution made by menstruums; but, in strictness, there is this difference, that in *solution* the menstruum absorbs the whole substance of the body, but in *extraction* it carries off only a certain part of it; and in this sense, camphor is dissolved in spirit of wine, but julap is more properly said

to be *extracted*; for the resin is only taken out by the menstruum, the other particles being left untouched.

EXTRACTION also frequently signifies such an inspissation, or thickening of a solution, as that a certain quantity of the menstruum being drawn off, the remaining mixture is reduced to the consistence of honey; as in the *extracts* of saffron, gentian, and the like.

Extracts are chiefly made from vegetables, and require different menstruums, according to the different nature of the plants, especially the gummous kind; for such as are mucilaginous, as gum Arabic, and tragacanth, &c. are not easily dissolved but in aqueous liquors; whereas resinous gums, as galbanum, scammony, &c. must have burning spirits to dissolve them.

There are others again of a middle nature, which may be dissolved in either sort of menstruums, though not so easily in one as the other; thus aloes, and rhubarb, which are something resinous, are better made into *extracts* with spirit of wine, than water; but plants, which abound less with resin, such as hellebore, &c. are more commodiously *extracted* with water.

To perform *extraction*, therefore, a proper menstruum is necessary, and one which is as *near* a-kin as possible to the body to be *extracted*.

EXTRACTION, in *Surgery*, denotes an operation whereby some foreign matter lodged in the body, contrary to the order of nature, is drawn out of the same by manual application, or the help of instruments.

Such is the *extraction* of a stone, formed in the bladder, or in the kidneys, &c.

EXTRACTION *of a Cataract*. See CATARACT.

Extraction belongs to the EXERESIS, as a species to its genus.

EXTRACTION, or *descent*, in *Genealogy*, denotes the stock, or family, which a person is descended from.

In some military orders, chapters, &c. a candidate must make proof of the nobility of his *extraction* before he is admitted.

EXTRACTION *of roots*, the method of finding the roots of given numbers, or quantities. See ROOT.

The square, cube, and other powers of a number, or root, are formed by multiplying the given number into itself a greater or less number of times, as the POWER required is higher or lower.

This multiplication compounds the powers: and the *extraction* of the root decompounds them again, or reduces them to their principles or roots. So that the *extraction* of the root is to the multiplication of the power, what the analysis is to the synthesis.

Thus, 4, multiplied by 4, produces 16; which is the square of 4, or the factum of 4, by itself; and 16, multiplied by 4, makes 64, which is the cube of 4, or the factum of 4 by its square. Such is the composition of powers.

Again, the square root of 16 is 4, because 4 is the quotient of 16 divided by 4; and the cube root of 64 is likewise 4, as is the quotient of 64 divided by the square of 4. Such is the *extraction* of roots.

Hence to *extract* the root out of a given power, is the same thing as to find a number, e. gr. 4, which being multiplied a certain number of times into itself, produces the given power, e. gr. 16 or 64.

For the *extraction* of square and cube roots, it is necessary to have the squares and cubes of all the digits in readiness; as exhibited in the following table.

Roots	1	2	3	4	5	6	7	8	9
Square	1	4	9	16	25	36	49	64	81
Cube	1	8	27	64	125	216	343	512	729

To extract the square root out of a given number. 1. Divide the given number into claſſes, of two figures a-piece; and include each claſs between two dots, commencing with the place of units, and proceeding to the left in integers, and to the right in decimals; the root will consiſt of so many parts, or figures, as you have claſſes. By the way obſerve, it may happen, that for the laſt claſs on the left-hand there ſhall only be one figure left.

2. Then the left-hand claſs being the ſquare of the firſt figure of the root ſought, look in the table of roots for the ſquare root anſwering to that number; or, if the ſquare number be not preciſely there, to the next leſſer number: this root write down for the firſt figure of the quotient; and ſubtract its ſquare from the firſt left-hand claſs. To the remainder bring down the next claſs toward the right.

3. Write down the double of the quotient figure under the left hand figure of the ſecond claſs; and ſeek how oft this duple is contained in the figure over it: the quotient gives the ſecond figure of the root.

4. Write the ſame quotient under the right-hand figure of the ſame claſs; and ſubtract the product of the whole number underwritten, multiplied by the ſecond figure of the root, from the number over it, as in diviſion.

5. The operation being repeated according to the third and fourth ſteps, i. e. the remainder being ſtill divided by the double of the root as far as *extracted*; and from the remainder ſubtract the product of the laſt diviſor, having the laſt found figure of the quotient added to it, multiplied by this figure, you will have the root required.

E. gr. To *extract* the root of 99856, point it after the following manner, 99856: then ſeek a number, whoſe ſquare ſhall equal the firſt figure 9, viz. 3. and write it in the quotient; then having ſubtracted from 9, 3×3, or 9, there will remain 0; to which ſet down the figures as far as the next point, viz. 98, for the following operation. Then taking no notice of the laſt figure 8, ſay, How many times is the double of 3, or 6, contained in the firſt figure 9? Anſwer, 1. Wherefore having written 1 in the quotient, ſubtract the product, of 1×61, or 61 from 98, and there will remain 37, to which connect the laſt figures 56, and you will have the number 3756, in which the work is next to be carried on. Wherefore alſo neglecting the laſt figure of this, viz. 6, ſay, How many times is the double of 31, or 62, contained in 375 which may be gueſſed at from the initial figures 6 and 37, by taking notice how many times 6 is contained in 37? Anſwer, 6, and writing 6 in the quotient, ſubtract 6×[illegible], and there will remain 0; whence it appears the buſineſs is done, the root coming out 16.

99856	316

73624	

first having pointed it, ſeek a number, whoſe ſquare (if it cannot be exactly equalled) ſhall be the next leſs ſquare (or neareſt) to 22, the figures to the firſt point, and you will find it to be 4. For 5×5, or 25, is greater than 22; and 4×4, or 16, is leſs; wherefore 4 will be the firſt figure of the root. This, therefore, being writ in the quotient, from 22 take the ſquare 4×4, or 16; and to the remainder 6, adjoin the next figures 17, and you will have 617; from whoſe diviſion, by the double of 4, you are to obtain the ſecond figure of the root, viz. neglecting the laſt figure 7, ſay, how many times 8 is contained in 61? Anſwer, 7; wherefore write 7 in the quotient, and from 617 take the product of 7 into 87, or 609, and there will remain 8, to which join the two next figures 87, and you will have 887; by the diviſion whereof by the double of 47, or 94, you are to obtain the third figure; in order to which ſay, how many times is 94 contained in 88? Anſwer, 0; wherefore write 0 in the quotient, and adjoin the two laſt figures 91, and you will have 88791, by whoſe diviſion by the double of 470, or 940, you are to obtain the laſt figure, viz. ſay, how many times 940 in 8879? Anſwer, 9; wherefore write 9 in the quotient, and you will have the root 4709. But ſince the product 9×9409, or 84681, ſubtracted from 88791, leaves 4110, the number 4709 is not the root of the number 22178791 preciſely, but a little leſs.

If then it be required to have the root approach nearer, carry on the operation in decimals, by adding to the remainder two cyphers in each operation. Thus the remainder

number 4 to, having two cyphers added to it, becomes 411000; the nineteen whereof, by the double of 4709, or 9418, will give the first decimal figure 4. Then having writ four in the quotient, subtract 4×94184, or 376736, from 411000, and there will remain 34264. And so having added two more cyphers, the work may be carried on at pleasure, the root at length coming out 4329, 43937, &c.

But when the root is carried on half-way or above, the rest of the figures may be obtained by division alone: as in this example, if you have a mind to *extract* the root to nine figures, after the five former 49094 are *extracted*, the four latter may be had, by dividing the remainder by the double of 47094.

Thus if the root of 329076 were to be *extracted* to five places, in numbers; after the figures are pointed, write 1 in the quotient, as being the figure whose square is 1, or 1, is the greatest that is contained in 3, the figure to the first point; and having taken the square of 1 from 3, there will remain 2; then having set the two next figures, viz. 29, to it (viz. to 2), seek how many times the double of 1, viz. 2, is contained in 22, and you will find indeed that it is contained more than ten times; but you are never to take your divisor to times, nor even 9 times in this case; because the product of 9×29, or 261, is greater than 229, from which it would be to be taken, or subtracted; wherefore write only 8. And then having written 8 in the quotient, and subtracted 8×28, or 224, there will remain 51 and having set down to this the figures 76, seek how many times the double of 18, or 36, is contained in 517, and you will find 1, and so write 1 in the quotient; and having subtracted 1×361, or 361, from 576, there will remain 215. Lastly, to obtain the remaining figures, divide this number 215, by the double of 181, viz. 362, and you will have the figures 59, which, being writ in the quotient, give the root 181,59. After the same manner are roots *extracted* out of decimal numbers. Thus, the root of 329,76 is 18,1595; and the root of 3,2976 is 1,81595; and the root of 0,032976, is 0,181595, and so on. But the root of 3297,6 is 57,42474; and the root of 32,976 is 5,742475. And thus the root of 9,94356 is 3,140.

329,76 (18,1595

361	
362)21559, &c.	

To extract the cubic, or higher root, out of a given number. The *extraction* of the cubic root, and all other roots, may be comprehended under one general rule; viz. every third figure, beginning from unity, is first to be pointed, if the root to be *extracted* be a cubic one; or every fifth, if it be a quadrato-cubic (or of the fifth power); and then such a figure is to be writ in the quotient, whose greatest power (that is, whole cube, if it be a cubic power, or whole quadrato-cube, if it be the fifth power, &c.) shall either be equal to the figure, or figures, before the first point, or next less under them; and then having subtracted that power, the next figure will be found by dividing the remainder augmented by the next figure of the resolvend, by the next least power of the quotient multiplied by the index of the power to be *extracted*, that is, by the triple square, if the root be a cubic one; or by the quintuple biquadrate (that is, five times the biquadrate), if the root be of the fifth power, &c. And having again subtracted the power of the whole quotient from the first resolvend, the third figure will be found by dividing that remainder, augmented by the next figure of the resolvend, by the next lesser power of the whole quotient, multiplied by the index of the power to be *extracted*.

Thus, to *extract* the cube root of 13312053, the number is first to be pointed after this manner, viz. 13312053, then you are to write the figure 2, whose cube is 8, to the first place of the quotient, as that which is the next lesser cube to the figure 13 (which is not a perfect cube number), or as far as the first point; and having subtracted that cube, there will remain 53 which being augmented by the next figure of the resolvend 3, and divided by the triple square of the quotient 2, by seeking how many times 3×4, or 12, is contained in 53, gives 4, or the second figure of the quotient. But since the cube of the quotient 24, viz. 13824, would come out too great to be subtracted from the figures 13312, that precede the second point, there must only 3 be writ in the quotient; then the quotient 23 being in a separate place multiplied by 23, gives the square 529, which again multiplied by 23, gives the cube 12167, and this taken from 13312, will leave 1145; which augmented by the next figure of the resolvend 0, and divided by the triple square of the quotient 23, viz. by seeking how many times 3×529, or 1587, is contained in 11450, gives 7, for the third figure of the quotient. Then the quotient 237, multiplied by 237, gives the square 56169, which again multiplied by 237, gives the cube 13312053; and this, taken from the resolvend, leaves 0. Whence it is evident, that the root sought is 237.

13312053 (237	
8

Subtract cube 12167	
1587) rem: 11450 (7	
	13312053
	Remains 0

So also, to *extract* the quadrato-cubical root of 36430820, it must be pointed over every fifth figure; and the figure 3, whose quadrato-cube, or fifth power 243 is the next lesser to 364, viz to the first point, must be writ in the quotient. Then the quadrato-cube 243 being subtracted from 365, there remains 122, which augmented by the next figure of the resolvend, viz. 3, and divided by five times the biquadrate of the quotient, viz. by seeking how many times 5×81, or 405 is contained in 1223, gives 2 for the second figure. That quotient 32, being thrice multiplied by itself, makes the biquadrate 1048576; and this again, multiplied by 32, makes the quadrato-cube 33554432, which, being subtracted from the resolvend, leaves 2876388. Therefore 32 is the integral part of the root, but not the true root; wherefore, if you have a mind to prosecute the work in decimals, the remainder, augmented by a cypher, must be divided by five times the aforesaid biquadrate of the quotient, by seeking how many times 5×1048576, or 5242880, is contained in 28763880, and there will come out the third figure, or the first decimal 5. And so by subtracting the quadrato-cube of the quotient 32,5 from the resolvend, and dividing the remainder by five times its biquadrate, the fourth figure may be obtained. And so on *in infinitum*.

405) 1223 (2	
33554432	
5242880) 2876388,0 (5	

In some cases, it is convenient only to indicate the *extraction* of a root, especially where it cannot be had exactly. Now, the sign, or character, whereby roots are denoted, is $\surd$; to which is added, the exponent of the power, if it be above a square, and even sometimes if it be not. E. gr. $\surd$ denotes the square root; $\surd^3$ the cube root, &c. See Root.

When a biquadratic root is to be *extracted* you may *extract* twice the square root, because $\surd^4$ is as much as $\surd^2 \times \surd^2$. And when the cubo-cubic root is to be *extracted*, you may first *extract* the cube root, and then the square root of that cube root, because the $\surd^6$ is the same as $\surd^2 \times \surd^3$; whence some have called these roots not cubocubic ones, but quadrato-cubic. And the same is to be observed in other roots, whose indices are not prime numbers.

To prove the extraction of roots. 1. For a *square root*: multiply the root found by itself, and to the product add the remainder, if there were any: if the sum be equal to the number given, the operation is just.

2. For a *cube root*. Multiply the root found by itself; and the product, again, by the same root. To the last product, add the remainder, if there were any. If the sum come out the number first given, the work is just.

After like manner may the *extraction* of the other roots be proved.

To extract the roots of equations, or algebraic quantities. The *extraction* of roots out of simple algebraic quantities, is evident, even from the nature, or mark of notation itself; as that $\surd aa$ is a, and that $\surd aacc$ is ac, and that $\surd 9aacc$ is $3ac$; and that $\surd 49a^4xx$ is $7aax$. And also that $\surd \frac{a^2}{cc}$, or $\frac{\surd a^2}{\surd cc}$ is $\frac{a}{c}$, and that $\surd \frac{a^2bb}{cc}$ is $\frac{aab}{c}$, and that $\surd \frac{9aaxx}{25bb}$ is $\frac{3ax}{5b}$, and that $\surd \frac{8b^6}{27a^3}$ is $\frac{2bb}{3a}$, and that $\surd \frac{aabb}{cc}$ is $\frac{ab}{c}$, and that $\surd aabb$ is $\surd abb$ moreover, that $b\surd aacc$, or b into $\surd aacc$, is equivalent to b into ac, or abc: and that $3c\surd \frac{9aaxx}{25bb}$, is equivalent to $3c \times \frac{3ax}{5b}$, or $\frac{9acx}{5b}$. And that $\frac{a+3x}{c} \surd \frac{4bbx^2}{81aa}$ is equivalent to $\frac{a+3x}{c} \times \frac{2bx}{9a}$, or to $\frac{2abx+6bx^2}{9ac}$. I say all these are evident, because it will appear at first sight, that the proposed quantities

are produced, by multiplying the roots into themſelves (as a a from 2 into a; 2 a c c from a c into 2 c; 9 a c c from 3 a c into 3 a c, &c.) The rule is to *extract* the required root of the numeral co-efficient, if there be any, and to divide the exponents of the literal or algebraic quantities by the number that denominates the root required. It is evident from the application of this rule, that any power which has a poſitive ſign may have either a poſitive or negative root, if the root is denominated by an even number; becauſe $+$ or $-$ multiplied into themſelves an even number of times will give $+$. Alſo, that if a power have a negative ſign, no root of it denominated by an even number can be aſſigned. But if the root to be extracted is denominated by an odd number, the ſign of the root will be the ſame as the ſign of the given quantity whoſe root is required. However, it will often happen, that the number denominating the required root will not exactly divide the exponent of the given power, in which caſe the required root will have a fractional exponent: thus, $\sqrt{8a^3}$ is $= 2a^{\frac{3}{2}}$. But when quantities conſiſt of ſeveral terms, the buſineſs is performed as in numbers.

Thus to *extract* the ſquare root out of $aa+2ab+bb$; in the firſt place, write the root of the firſt term aa, viz. a, in the quotient, and having ſubtracted its ſquare $a \times a$, there will remain $2ab+bb$ to find the remainder of the root by. Say, therefore, how many times is the double of the quotient or, $2a$, contained in the firſt term of the remainder $2ab$? I anſwer, b [times]: therefore write b in the quotient, and having ſubtracted the product of b into $2a+b$, or $2ab+bb$, there will remain nothing; which ſhews that the work is finiſhed, the root coming out $a+b$.

$aa+2ab+bb(a+b$
aa
$2a+b)2ab+bb$
$+2ab+bb$
$0\quad 0$

And thus to *extract* the ſquare root out of $a^4+6a^3b+5a^2bb-12ab^3+4b^4$, firſt let in the quotient the root of the firſt term a^4, viz. aa; and having ſubtracted its ſquare $aa \times aa$, or a^4, there will remain $6a^3b+5a^2bb-12ab^3+4b^4$ to find the remainder of the root. Say, therefore, how many times is $2aa$ contained in $6a^3b$? Anſwer $3ab$; wherefore write $3ab$ in the quotient; and having ſubtracted the product of $3ab$, into $2aa+3ab$, or $6a^3b+9a^2bb$, there will yet remain $-4a^2bb-12ab^3+4b^4$ to carry on the work. Therefore, ſay again, how many times is the double of the quotient, viz. $2aa+6ab$, contained in $-4a^2bb-12ab^3$? or, which is the ſame thing, ſay, how many times is the double of the firſt term of the quotient, or $2aa$, contained in the firſt term of the remainder $-4a^2bb$? Anſwer $-2bb$. Therefore having writ $-2bb$ in the quotient, and ſubtracted the product $-2bb$ into $2aa+6ab-2bb$, or $-4a^2bb-12ab^3+4b^4$, there will remain nothing.

Whence it follows, that the root is $aa+3ab-2bb$.

$a^4+6a^3b+5a^2bb-12ab^3+4b^4(aa+3ab-2bb$
a^4
$2aa+3ab)6a^3b+5a^2bb$
$+6a^3b+9a^2bb$
$0\quad -4a^2bb-12ab^3+4b^4$
$\quad -4a^2bb-12ab^3+4b^4$
$\quad 0\quad 0$

And thus the ſquare root of the quantity $xx-2x+\frac{1}{2}aa$ is $x-\frac{1}{2}a$; and the ſquare root of the quantity $y^4+4y^3+8y^2+8y+4$ is $yy+2y+2$; and the ſquare root of the quantity $16a^2-24aax+9x^4+12bbxx-16aabb+4b^4$ is $3ax-4aa+2bb$, as may appear underneath:

1. $xx-2x+\frac{1}{2}aa(x-\frac{1}{2}a$
xx
$2x-\frac{1}{2}a)-2ax+\frac{1}{2}aa$
$0\quad 0$

2. $9x^4-24ax^3+12bbxx+16a^2-16aabb+4b^4(3xx-4ax+2bb$
$9x^4$
$6xx-4ax)-24ax^3+12bbxx$
$-24ax^3+12bbxx+16a^2b^2-16a^2bb+4b^4$
$0\quad 0$

3. $y^4+4y^3+8y^2+8y+4(yy+2y+2$
y^4
$2y+y)4y^3+8y^2$
$4y^3+8y^2+4y+4$
$0+4y+4$

If you would extract the cube root out of $a^6-3a^5b+3a^4bb-b^3$, the operation is performed thus:

$a^6-3a^5b+3a^4bb-b^3(a^2-ab$
a^6
$3aa)0+3a^5b$
$+3a^5b-3a^4bb+a^3bb$
$0\quad 0$

Extract firſt the cube root of the firſt term a^6, viz. a^2, and ſet it down in the quotient: then ſubtracting its cube a^6, ſay, how many times is its triple ſquare, or $3aa$, contained in the next term of the remainder $-3a^5b$? and there comes out $-b$; wherefore write $-b$ in the quotient, and ſubtracting the cube of the quotient $-b^3$, there will remain 0; therefore a^2-b is the root. After the ſame manner, if the cube root is to be *extracted* out of $x^6+6x^5-40x^3+96x-64$, it will come out $xx+2x-4$. And ſo likewiſe in higher roots.

The general rule for *extracting* any root out of any given quantity, is as follows. Having ranged the quantity according to the dimenſions of its letters, *extract* the ſaid root out of the firſt term; and that ſhall be the firſt member of the root required; then raiſe this root to a dimenſion lower by unit than the number that denominates the root required, and multiply the power that ariſes by that number; laſtly, divide the ſecond term of the given quantity by the product, and the quotient ſhall give the ſecond member of the root required. The other members of the root are found after the ſame manner; but when two are found after the firſt, you muſt proceed to the third, becauſe the exact root cannot be found [illegible], the ſquare root of a^4+ [illegible] $\frac{5a^6}{12a^4}$, &c.

The operation is thus:

$a^n+x^n(a+\frac{x^n}{na}-\frac{n-1}{2n^2a^{n+1}}+\frac{3n^2-3n+1}{6n^3a^{2n+1}}$, &c.
a^n
$na+\frac{x^n}{a})\frac{x^n}{a}+x^n$
$\times\frac{x^n}{na}=a^n+\frac{x^n}{n^2}$
$na+\frac{x^n}{a}-\frac{n-1}{2n^2a})-\frac{n-1}{2n^2}x^n$
$\times-\frac{x^n}{na}=-\frac{n-1}{2n^2}x^n+\frac{n^2-3n+2}{6n^3a}x^n$
$+\frac{n^2-3n+1}{2n^2a}-\frac{n^2-3n+2}{6n^3a}$, &c.

In the ſame manner the cube root of a^3+x^3 will be found to be $a+\frac{x^3}{3a^2}-\frac{x^6}{9a^5}+\frac{7x^9}{81a^8}-\frac{10x^{12}}{243a^{11}}$, &c. Thus,

$a^3+x^3(a+\frac{x^3}{3a^2}$
$3a^2)a^3$
$3a^2)a^3+x^3$

Then cube $a+\frac{x^3}{3a^2}$, and we ſhall have $a^3+x^3+\frac{x^6}{3a^3}+\frac{x^9}{27a^6}$, which, ſubtracted from the given quantity a^3+x^3, leaves $-\frac{x^6}{3a^3}-\frac{x^9}{27a^6}$ for the next reſolvend; and this divided by $3a^2$ will give $-\frac{x^6}{9a^5}$ for the next term of the quotient, &c. But the roots of quantities of this kind are much more expeditiouſly obtained by means of the BINOMIAL *theorem*. For the ſquare root of a^2+x^2 $=a^2+x^2\times\frac{1}{2}$, and $a^2+x^2\times\frac{1}{3}=a^{\frac{2}{3}}+\frac{1}{3}\times a^{\frac{2}{3}-1}\times x^2+\frac{\frac{1}{3}-1}{2}\times a^{\frac{2}{3}-2}\times x^4+\frac{\frac{1}{3}-1}{2}\times\frac{\frac{1}{3}-2}{3}\times a^{\frac{2}{3}-3}\times x^6$, &c. $=a^{\frac{2}{3}}+\frac{1}{3}\times a^{-\frac{1}{3}}x^2+\frac{1}{3}\times-\frac{1}{3}\times a^{-\frac{4}{3}}x^4+\frac{1}{3}\times-\frac{1}{3}\times-\frac{4}{3}\times a^{-\frac{7}{3}}x^6$, &c. $=a^{\frac{2}{3}}+\frac{1}{3}\times a^{-\frac{1}{3}}x^2-\frac{1}{9}\times a^{-\frac{4}{3}}x^4+\frac{4}{81}\times a^{-\frac{7}{3}}x^6$, &c. $=$ (by the powers of a from the numerators to the denominators,

by

by changing the ſigns of their exponents) $a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5}$, &c.

Thus alſo the cube root of $a^3 + x^3 = a^3\left(1 + \frac{x^3}{a^3}\right)^{\frac{1}{3}}$, and $\left(a^3 + x^3\right)^{\frac{1}{3}} = a\left(1 + \frac{x^3}{a^3}\right)^{\frac{1}{3}} = a^{\frac{1}{3}} \times 1^{\frac{1}{3}-1} \times x^3 \times \frac{1}{3} \times \frac{\frac{1}{3}-1}{2} \times a^{\frac{1}{3}-2} \times x^6 \times \frac{1}{2 \cdot 3} \times \frac{\frac{1}{3}-1}{3} \times \frac{\frac{1}{3}-2}{3} \times a^{\frac{1}{3}-3} \times x^9$, &c. $= a^{\frac{1}{3}} + \frac{1}{3} \times a^{-\frac{2}{3}} x^3 - \frac{1}{9} \times a^{-\frac{5}{3}} x^6 + \frac{5}{81} \times a^{-\frac{8}{3}} x^9$, &c. $= a + \frac{x^3}{3a^2} - \frac{x^6}{9a^5} + \frac{5x^9}{81a^8}$, &c. See Maclaurin's Algebra, part i. ch. viii. p. 60, 61. See Root.

EXTRACTOR, in *Midwifery*, an inſtrument contrived to extract children in caſes of difficult births. We have the deſcription of a forceps for extracting children by the head, when lodged low in the pelvis of the mother, in the Medic. Eſſ. Edinb. vol. iii. art. 25. See alſo the abridgment of this book, vol. ii. p. 298, where ſome alteration is mentioned of this inſtrument from Giffard's Midwifery, and an improvement of it by Mr. Freke.

EXTRACTUM *colloquintidæ*, a form of medicine in the London Diſpenſatory, intended as an equivalent for the *extractum Rufi*, commonly called Rudius's pill. It is made in this manner: take Socotrine aloes an ounce and half; pith of coloquintida, ſix drams; ſcammony, and the leſſer cardamom ſeeds huſked, of each half an ounce; proof ſpirit a pint; pour the ſpirit on the coloquintida cut ſmall; then add the aloes and ſcammony, firſt ſeparately reduced to powder, and theſe being diſſolved, draw off the ſpirit, and reduce the maſs by evaporation to the conſiſtence of a pill. This for many reaſons is a better compoſition than the Rudian's pill.

EXTRADOS, the outſide of a vault.

EXTRANEOUS *matter*. See Motion.

EXTRAORDINARII, in *Roman Antiquity*, a body of forces conſiſting of a third part of the horſe, and a fifth part of the foot, which was ſeparated from the reſt, to prevent any deſign that might be formed againſt the natural forces. See Ablecti.

EXTRAORDINARY, ſomething out of the common courſe.

Extraordinary *couriers*, are thoſe ſent expreſs on ſome urgent occaſion.

Extraordinary *ambaſſador, or envoy*, is ſuch a one as is ſent to treat or negociate ſome ſpecial and important affair, as a marriage, a treaty, confederacy, &c. or even on occaſion of ſome ceremony, as condolence, congratulation, &c. See Embassador.

A Gazette, journal, or other News-paper *extraordinary*, is that publiſhed after ſome great and notable event, containing the details of particulars thereof, which are not found in the ordinary papers. Our news-mongers generally uſe poſtſcripts, or ſupplements, inſtead of *extraordinaries*.

Extraordinary *cultivation*. See Cultivation.

EXTRAVAGANTES, a part of the canon law, conſiſting of ſeven conſtitutions of the pope, not included in the body of the canon law; whence the denomination *extravagantes*, *quaſi extra corpus juris vagantes*.

The *extravagantes* are divided into two parts: the firſt contains twenty conſtitutions of John XXII. and the ſecond, other later conſtitutions of the laſt John, and his ſucceſſors. See Canon Law, and Decretals.

EXTRAVASATION, formed of *extra*, *without*, and *vas*, *veſſel*, in *Medicine*, a motion of the blood, whereby it breaks out of its ordinary veſſels, the veins or arteries, and either gathers, and ſtagnates in ſome firſt part, or is thrown quite out of the body.

The ordinary cauſes of *extravaſation*, are unnatural repletions, and diſtenſions of the veſſels; or lacerations, and eroſions thereof. There is a neceſſity for bleeding, to prevent the blood's accumulating ſo as to *extravaſate*. In wounds of the head, particularly, bleeding is neceſſary, to prevent the *extravaſation* of the blood in the brain.

In the contuſions, fiſſures, depreſſions, fractures, and other accidents of the cranium, one or more of the blood-veſſels diſtributed on the *dura mater* are frequently divided. The blood that is diſcharged from theſe veſſels greatly oppreſſes the brain, and diſturbs its offices; frequently brings on pains and other miſchiefs, and often death itſelf, unleſs the patient be timely relieved. If the quantity of *extravaſated* blood be ever ſo ſmall, it will certainly corrupt and affect the meninges, and the brain itſelf with the ſame diſorder; and from hence will proceed violent inflammations, deliriums, and ulcers, and finally death; and this will frequently be the caſe, after a violent blow upon the cranium, though the bone ſhould eſcape without injury. In theſe injuries of the head, the blood is ſpilt either between the cranium and the *dura mater*, or between the *dura* and *pia mater*, or between the *pia mater* and the brain, or laſtly into the ſinuſes of the brain. Either of theſe caſes is attended with very great danger; but the deeper the *extravaſation* happens, ſo much greater muſt the danger be. Blood *extravaſated* in the cavity of the cranium, will be diſcovered from the violence of the ſymptoms that ſucceed a blow on the head; as if the patient lies ſtill without ſenſe or motion, if blood flows from the mouth, ears, or noſe; if the eyes are much inflamed and ſwelled; if vomitings ſucceed; when upon the remiſſion of theſe ſymptoms the patient complains of a remarkable heavineſs of head, ſleepineſs, vertigo, blindneſs, ſpaſms, and diſorders of this kind. When the quantity of *extravaſated* blood on theſe accidents is very conſiderable, and oppreſſes the cerebellum, the patient dies upon the ſpot; but when it is not in a very large quantity, or does not affect the cerebellum, life ſtill remains, but the ſymptoms juſt mentioned come on. In this caſe, if no fiſſure, or contuſſure is to be found, nor any external injury on the integuments of the head after a violent blow, it proves very difficult to find in what part of the head the *extravaſation* is ſeated. It will be proper in this caſe ſtill to ſhave the head all over, and then thoroughly to examine it; for if any part is ſofter than ordinary, or is enlarged, or red from ſtagnating blood, it is plain that this is the part that has received the injury. But if neither in this way, nor by inquiry among the perſons preſent at the accident, you can get light into the affair, it will be proper to cover the whole head with an emollient plaiſter, laying over it medicated bags of herbs, &c. well heated. This application will in a few hours time produce a tumor and ſoftneſs upon the injured part. Sometimes the patient alſo, though he lies ſpeechleſs, and ſeemingly ſenſeleſs, will be continually putting his hand to the injured part; and if either ſide of the patient has loſt ſenſe or motion, and is become paralytic, it is an apparent ſign, whatever ſome might think to the contrary, that the injury has been received on the contrary or ſound ſide. If after accidents of this kind you can diſcover any wound in the ſkin, that muſt be enlarged with the knife till the injury of the cranium, of whatever kind it be, is come at.

When the ſeat of the injury is diſcovered, the firſt intention is to diſcharge the *extravaſated* blood, and then to clean the wound, and remove all ſplinters, or extraneous bodies. Some have recourſe on theſe occaſions to the inſtrument of the trepan; but patients have been often very ſucceſsfully recovered without it. It is therefore beſt firſt to open a vein, and take away as much blood as the ſtrength of the patient will permit; this will take off the impetus of the veſſels, and prevent the *extravaſation* of more blood. Preſcribe after this a brisk purge to leſſen the quantity of the fluids; foment the head with medicated bags, and apply a meſſlot plaiſter to it; endeavour to rouſe the patient by volatile applications to the noſtrils, ſuch as ſal volatile, ſpirit of ſal ammoniac, or ſpirit of hartſhorn: and give frequently attenuating fluids, ſuch as the decoctions of betony, ſage, roſemary, lavender-flowers, ſaſſafras, and the like. This method does not immediately produce the deſired effect, but is to be continued for ſome time, and the preſcriptions frequently repeated, particularly when the bad ſymptoms ſeem by degrees to abate; and if the patient finds relief from the firſt bleeding, it will be proper to repeat it a ſecond or third time, eſpecially if he be of an athletic conſtitution. When notwithſtanding this method, the ſymptoms are found however rather to increaſe than abate, it will be neceſſary to make a perforation in the cranium with the trepan, to give a paſſage for the diſcharge of the confined grumous blood; and when there is no finding out the part affected, the ſkull muſt be perforated in ſeveral parts till the right is found. Heiſter's Surg. p. 90. See Ecchymosis.

Extravasation is ſometimes likewiſe uſed in ſpeaking of other humours beſide the blood; as the lympha, urine, &c. The gardeners uſe the term in ſpeaking of gums, juices, &c. which oufe out of their trees either ſpontaneouſly, or at inciſions.

EXTRAVERSIO, in *Chemiſtry*, a term uſed to expreſs the rendering manifeſt any thing ſaline, alcaline, or acid, concealed in mixed bodies; and is juſt the reverſe to one of the ſpecies of concentration, which hides theſe qualities.

EXTREAM, or EXTREME, is applied to the laſt and outermoſt part of any thing, or that which finiſhes and terminates it on that ſide.

The *extremes* of a line are points. There is no paſſing from one *extreme* into the other, without going through the middle. *Extreme* remedies muſt only be had recourſe to in *extream* neceſſity.

Some anatomiſts apply the denomination *extreams*, or *extremities*, to the arms and legs.

The arms, or upper *extremities*, conſiſt of ſixty-two bones, thirty-one in each, viz. the omoplate, humerus, cubites, radius, eight in the carpus, four in the metacarpus, and fifteen in the fingers.

The *lower extremities*, or legs, conſiſt of ſixty; thirty in each; viz. the femur, rotula, ilia, fibula, ſeven in the *tarſus*, five in the metatarſus, and fourteen in the toes.

Galen, in his comment on the prognoſtics, obſerves, that theſe parts in acute diſeaſes often afford great matter for prognoſtication; ſince death never happens without ſome alteration in thoſe parts, from their natural ſtate; for in dying perſons the *extream* parts are preſently refrigerated, and turn livid and black; and oftentimes the hands and feet are ſubject to cold and irregular motions.

EXTREAMS, in *Logic*, denote the two *extream* terms of the concluſion of a ſyllogiſm; viz. the predicate and ſubject. They are called *extreams*, from their relation to another term, which is a medium or mean between them.

The predicate, as being likewiſe laid in the firſt propoſition, is called the *major extremum*, *greater extream*; and the ſubject, as being put in the ſecond, or minor, propoſition, is called the *minus extremum*, *leſſer extream*.

Thus, in the ſyllogiſm, man is an animal; Peter is a man, therefore Peter is an animal; the word animal is the greater *extream*, Peter the leſs *extream*, and the man the medium. See SYLLOGISM.

EXTREAM *and mean proportion*, in *Geometry*, is when a line is ſo divided, that the whole line is to the greater ſegment, as that ſegment is to the other.

O', as Euclid expreſſeth it, when the line is ſo divided, that the rectangle under the whole line, and the leſſer ſegment, is equal to the ſquare of the greater ſegment.

The invention of this diviſion is thus: let the given line be AB = *a* (*Vid.* II. *Geometry, fig.* 43.) and for the greater ſegment put *x*, the leſſer will be *a* − *x*. Then, by the hypotheſis, *a* : *x* :: *x* : *a* − *x*. Therefore *a* *a* − *a* *x* = *x x*, conſequently *a aa* − *ax* + *x x*. And, by *adding* ¼ *a a* on each ſide, to make *x x* + *ax* + ¼ *a a* a compleat ſquare, the equation will ſtand thus, ¼ *aa* − *ax* + *x x* = ¼ *a a*.

Now, ſince the latter is exactly a ſquare, its root ½ *a* − *x* = √ ¼ *aa*, and by tranſpoſition it will be √ ¼ *aa* − ½ *a* = *x*; which laſt equation is a canon for finding *x*.

For at the foot of AB = *a*, let at right angles CB = ½ *a*; then draw CA, the ſquare of which is equal AB *q* + CB *q* = ¼ *a a*. And therefore AC = √ ¼ *aa*; make CD = CA. From whence CB = ½ *a* being taken, as the caſe requires, there remains BD = *x*, which tranſferred into AB, ſhall give the point E, where AB is cut according to *extream and mean proportion*.

This cannot be exactly done in numbers; but if you would have it tolerably near, add together the ſquare of any number, and the ſquare of its half, and extract, as near as you can, the ſquare root of the ſum; from whence taking half, the remainder is the greater part.

EXTREAMS, in right-angled ſpherical trigonometry. When one of the five circular parts of a right-angled ſpherical triangle, viz. the three ſides and two oblique angles, (for the right angle is neglected) is pitched upon for the middle term, then the two circular parts lying immediately next to it are called *extreams conjunct*; and the two parts remote from the aſſumed middle part, or not immediately next it, *extreams disjunct*. See CIRCULAR *parts*, TRIANGLE, and TRIGONOMETRY.

EXTREAM UNCTION, one of the ſacraments of the Romiſh church, the laſt in order, adminiſtered to people dangerouſly ſick, by anointing them with holy oils, and pronouncing ſeveral prayers over them. See UNCTION. It is called *extream unction*, as being only given to perſons in *extremity*. In the thirteenth century, it was called the *unction of the ſick*, and not *extream unction*: for, in the earlier ages, it was given before the *catechumens*; which practice, according to F. Mabillon, was not changed till the thirteenth century.

The reaſons he aſſigns for the change are, that in that age there aroſe divers miſtaken opinions, ſeveral of which we find mentioned and condemned in the Engliſh councils: among the reſt, it was held, that ſuch as had received this ſacrament, in caſe they recovered, might no more uſe of their wives, nor eat meat, nor go barefooted; whence they choſe to forbear it till the laſt extremity; which practice prevailed. See the councils of Worceſter and Exeter, in the year 1287; that of Wincheſter, in 1308; and F. Mabillon, Acta Sanct. Bened. Sæc. iii. pa. 1.

The form of *extream unction* is now deprecative, as the divines call it; formerly it was abſolute, and indicative. This ſacrament is not only in uſe in the Latin, but alſo in the Greek church, and throughout the Eaſt, though under another name, and with ſome difference in the circumſtances; in that the orientals do not wait till their ſick are come to extremity, in order to anoint them; but the ſick generally go to church themſelves; and it is adminiſtered to them as often as they are indiſpoſed; the Greeks taking that direction of St. James, chap. v. ver. 14. which is the foundation of the practice, in a general ſenſe: *Is any ſick among you? let him call for the elders of the church, and let them pray over him, anointing him with oil.* F. Dandini diſtinguiſhes two kinds of *unction* among the Maronites; the one called *unction with the oil of the lamp*; but this he ſuggeſts, is not the ſacramental *unction* ordinarily adminiſtered to ſuch as are in extreme ſickneſs; becauſe the oil is only conſecrated by a prieſt, and it is given to all who are preſent; not to the ſick only, but alſo to the healthy; even the prieſt who conſecrates partakes of it. The other kind of *unction*, according to that father, is only for the ſick: this is performed with oil conſecrated by the biſhop alone, on Holy Thurſday; and that is ſeemingly in their ſacramental *unction*.

The *unction* with lamp-oil is in uſe, not only among the Maronites, but throughout all the eaſtern church, who uſe it very religiouſly. The truth is, they do not ſeem to have any other ſacrament of *extream unction* beſide this. Yet F. Goar obſerves, though it be only a ceremony, with regard to thoſe in health, it is a real ſacrament to thoſe that are ſick.

In their great churches there [illegible], wherein this oil for the ſick is preſerved. [illegible] call *unction ta nygkoma*; that is, *the [illegible] muſt pray*; for what the Latins call *extream unction*, the Greeks call *euchelaion*, or *euchelaion [illegible] prayer*, or *holy oil*.

EXTREMITIES [illegible] *members*, is uſed for the head, hands, [illegible] which ſhould be drawn with more nicety and [illegible], or more terminated than other parts; and [illegible] help to render the action more expreſſive.

EXTREMUM *clauſæ dicm.* See DIEM.

EXTRINSIC is applied, in the *Schools*, to various ſenſes. Sometimes it ſignifies a thing's not belonging to the eſſence of another: in which ſenſe, the efficient cauſe, and the end, or ſcope, of a thing, are ſaid to be *extrinſic*, or *extrinſic cauſes*.

Sometimes it implies a thing not being contained within the compaſs of another. In which ſenſe, thoſe cauſes are ſaid to be *extrinſic*, which introduce ſomething into a ſubject from without: as when fire introduces heat, &c. Sometimes it denotes a thing added, or applied to another. Thus, accidents and adherences are ſaid to be *extrinſic* to the ſubject; and thus virtue is *extrinſic* to the ſpecific form.

EXTRINSIC *argument*, *Service*, &c. See the ſubſtantives.

EXUBERANCES, in *Medicine*, are fleſhinges forth, or riſings up in the fleſh, or other parts of the body.

EXUBERANCE, compounded of *ex* and *uber*, *plentiful*; of *uber*, *udder*, in *Rhetoric*, a redundancy. See REDUNDANCE, and PLEONASM.

EXUDATION, the act of ſweating out. In which manner, gums, balſams, &c. are uſually produced from trees.

EXUCONTIANI, a branch of Arian hereties. See EXUCONTII.

EXVERRA, in *Antiquity*, a kind of broth uſed in cleanſing houſes, out of which a dead perſon had been carried.

EXULCERATION, in *Medicine*, the act of caſting, or producing ulcers.

Thus, *aſthenic exulcerations* are cauſed by a weakneſs of the fibres; *cachectic exulcerations* by the ſame.

EXULCERATION is ſometimes alſo uſed for an ULCER itſelf; but, more generally, for thoſe beginning eroſions which wear away the ſubſtance, and form ulcers.

Exulcerations in the inteſtines are marks of poiſon.

EXUPORA, in *Botany*, a name by which ſome authors have called the verbena, or common vervain.

EXUSTION, of *ex* and *uro*, *I burn*, the act of burning with fire; uſed in ſome operations by ſurgeons. See BURN.

EXUVIÆ, formed from *exuo*, *to put off*, *to diveſt*, in *Phyſiology*, tranſient parts of certain animals, which they put off, or lay *down*, and aſſume new ones.

Such, eſpecially, are the ſkins, or *ſloughs*, of ſerpents; ſhells of lobſters, and the like; which are annually changed, and renewed in the ſpring.

The outer integument of the body, which in man and other larger animals is ſo durably fixed on the body, is

in many of the animals of the reptile kind much more loosely fixed, and is changeable several times during the period of their lives. The serpent-kind all shift their skins several times in their lives, and the water-newt has been lately observed to do the same; but no creature in the world does it so often as the caterpillar, almost every species of these insects throwing off their old skin once in ten or twelve days, or less; and this in such a manner as is extremely worthy an attentive observation. Malpighi observed that the common silkworm changed its skin four times during its continuance in that state; the first of these changes happening at eleven or twelve days from its appearance from the egg, and the others at the distance of five or six days each; and probably the rest of the caterpillar kind observe nearly the same periods.

Neither is this change of the skin confined to the few creatures we have mentioned; but among the whole insect class, the most numerous of that of all animated beings we know, there is scarce one species every individual of which does not throw of its skin, once at least, before it arrives at its full growth. The term changing the skin is scarce expressive enough for this operation in the caterpillar-kinds; for the creature throws off the external covering of every the minutest part and organ of its body, and the skins they thus deposit have so much the appearance of a complete insect, that they are very often mistaken for such, presenting us with every thing that we see in the external appearance of the living animal. If the caterpillar has been one of the hairy kinds, the skin which it throws off is hairy, containing the integument as it were of every hair and of each of the legs; and even the claws and other parts, which are not visible without the assistance of a microscope, are as plain in this as in the living animal. But what is most of all amazing, is to find that the very solid parts which form the head, are also found in the *exuviæ*, the skull and teeth being plainly distinguishable in them; it is easy to conceive that this must be a strange operation, for an animal in this manner to withdraw the several parts of its body out of their sheaths and cases, which they have plainly been fitted into in so nice a manner; and particularly the throwing off an old skull and teeth to make way for new ones, seems an act beyond all comprehension. The operation, however, appears as tedious and painful to the animal as we can expect; if we examine it strictly a day or two before this change happens, the creature always refuses to eat, and loses its former activity; either never walking at all, or at the utmost but very slowly; though they do not move out of their places, however, they are very full of some particular motions in their body; they turn themselves about from side to side, and often elevate their back, and then gently depress it again; they frequently raise up their heads, and strike them down rudely against the things they stand upon, and frequently the anterior half of the body is raised from the place, and thrust very briskly backwards and forwards from side to side, for three or four times together. These are the more obvious motions; but beside these there are other less sensible ones within every ring; these are separately inflated and contracted again alternately, and by this means the skin is greatly loosened from them; and by these motions, and the remaining without food, it is that the body by degrees disengages itself from the skin. Reaumur, Hist. Ins. vol. i. part 1. p. 225.

M. Reaumur observed three or four hairy caterpillars, at the time when they were just preparing for their change; and when they shewed the very first signs of its approaching, by ceasing to eat and move, he cut, with a fine pair of scissars, many of the hairs off, as close to the body as he could. When the change was perfected, and this skin thrown off, he examined the hairs of the parts, corresponding to those he had cut them short upon in the old skin, while yet upon the animal. If these had been the cases of the new hairs, those must certainly have been cut short with them; but, on the contrary, they were found, in the caterpillar, as long in those parts as in any others. It appears from hence, that though all the other parts thrown off are but the sheaths and cases to what they covered, yet the hairs are real and solid things themselves; and hence it appears, that the creature, when hatched from the egg, must have all its skins perfectly formed, one lying under another, and each furnished with its covering of hairs, so that the old ones are to fall off with the old skins, and the new ones to appear with the new; and probably this may be one great means of forcing off and dislodging the old skin from every part, by the creature's erecting them in part. Ibid. p. 241.

EXUVIÆ is also used for some shells, and other marine bodies, frequently found in the bowels of the earth; supposed to have been deposited there at the deluge, as being the real spoils of once living creatures. See SHELL, FOSSIL, and DELUGE.

EY, in our *Old Writers*, the same with *insula*, an *island*; from which comes *eyot*, a small island or islet, vulgarly called *eyght*.

EYE, the organ, or part of the body, whereby vision is effected; i. e whereby visible objects are represented to the mind. The *eye*, or organ of sight, is generally divided into *internal* and *external* parts; or into the *eye properly so called*, and the *appendages* thereof.

Under the latter class come the *orbit*, or cavity, wherein the *eye* is placed; the *supercilium*, or *eye-brow*, whereby the rays of light are moderated in their passage to the *eye*, and sweat, and other nuisances, are prevented from falling down into it, though both these purposes are better answered by the anterior and inferior part of the *os frontis*; the *palpebræ*, or *eye-lids*, which cover and defend it in time of sleep; with their *cilia*, or fringes of hair, to break the too fierce impression of the light, and keep off flies and moats, and by their frequent motions to assist in diffusing the tears, and oily secretions of the sebaceous or ciliary glands of the *eye-lids*, equally over the surface of the globe of the *eye*; and the *canthi*, or angles. The *eye*, *properly so called*, is of a globular form, and consists of tunics, humours, and vessels.

In some parts it is lined with fat, and it is moved with muscles; which two latter are by some anatomists, though somewhat inaccurately, reckoned among the constituent parts of the *eye*. The *tunics*, *coats*, or *membranes*, *of the eye*, are seven; viz. 1. The *adnata*, or *conjunctiva*, covering the whole ball of the *eye*, except the fore-part, called the sight. 2. The *tunica albuginea*, which is placed immediately under the former, and is formed by the expanded tendons of the four straight muscles of the globe of the *eye*. These two, which some consider only as one coat, are called partial coats, because they invest only a part of the globe of the *eye*. 3. Immediately under the *adnata* and *albuginea*, is the *sclerotica*, which covers the whole globe of the *eye*; being opake everywhere but in the fore-part, which covers the sight, and is transparent like horn; which has occasioned anatomists to account this a distinct membrane, the fourth in number, and to denominate it the *cornea*. The fifth is the *choroides*, situate immediately under the *sclerotica*: the internal surface of the *choroides*, called the *tunica Ruyschiana*, from professor Ruysch, or the vascular coat from its texture, immediately invests the external or posterior surface of the *retina*; its fore-part, like the former, is transparent, and therefore accounted a distinct, or sixth coat, and called the *uvea*. Of the duplicature of this part of the tunic, is formed a striped, variegated circle, called the *iris*, which, in different subjects, is of different colours, and gives the denomination of this or that colour to the *eye*. Near its middle is an aperture, or perforation, called the *pupil*, or *apple of the eye*, about which the iris forms a ring; from the inside of this tunic spring certain fibres, which spreading round the crystalline humour, form the *ligamentum ciliare*. The seventh tunic, which some only make the third, is the *retina*, so called, as resembling a net, and covering only the fund, or bottom, of the *eye*, opposite to the sight.

Of the three proper tunics, the *sclerotica*, *choroides*, and *retina*, the first is derived from the *dura mater*, being detached from the brain as an outer coat, or cover, of the optic nerve, till, arriving at the ball of the *eye*, it is there expanded into a tunic: the second is derived from the *pia mater*, and transmitted likewise from the brain, along with the optic nerve; the third may be said to be derived from the brain, or *medulla* itself, as being an expansion of the medullary substance of the optic nerve. See each tunic described under its proper article. See also IRIS and PUPIL.

The *humours of the eye*, inclosed between these tunics, are three, viz. 1. The *aqueous*, a limpid, transparent humour, situate in the fore-part of the *eye*, immediately under the *cornea*, and occasioning its protuberance. 2. The *crystalline*, situate immediately under the aqueous, behind the *uvea*, opposite to the pupil. 3. The *vitreous*, or glassy humour which fills all the hind part of the cavity of the globe; and is that which gives the spherical figure of the *eye*: on its back part is the *retina* spread. See each humour under its proper article, AQUEOUS, CRYSTALLINE, and VITREOUS.

Some authors, finding these humours covered with proper membranes, have given distinct names to them; as the *aqueous*, *crystalline*, and *vitreous tunics*; but these being only productions of the other coats above mentioned, the distinction is not much regarded. See the situation of the several coats and humours above described, represented by a figure of the *eye*, in *Tab.* II. *Optics*, *fig.* 20. *aa* is the *sclerotica*; A A the *cornea*; *cc* the *choroides*; *pp* the *pupil*; *bp*, *bp*, the *iris*; CC the *crystalline humour*,

ſuſpended by *l*, *l*, the *ligamenta ciliaria*, or *proceſſus ciliares*; NN the optic nerve, the expanſion of which, as far as the *ligamenta ciliaria*, forms the *retina*. The *aqueous humour* is contained in the cavity lying between the *cryſtalline* and the *cornea*; and the larger cavity, beyond the *cryſtalline*, is occupied by the *vitreous humour*.

The veſſels of the eye are, nerves, glands, arteries, and veins. 1. The nerves are the optic pair, which, iſſuing through a perforation in the ſkull, behind the orbit, enter the ball of the *eye*, and diffuſe and loſe themſelves therein; the outer coat, as already obſerved, going to form the *ſclerotica*, the inner to the *choroides*, and the *medulla* to the *retina*.

Beſides which, the *motorii*, *pathetici*, the firſt branch of the fifth pair, called *ophthalmici*, and the ſixth pair, are beſtowed on the muſcles of the *eye*.

2. On the upper part of the ball of the *eye*, near the leſſer or outer canthus, is the *glandula innominata*, or *lachrymalis*, which ſeparates the matter of the tears, to be diſcharged by the continual motion of the *eye-lid* upon the *cornea*, to moiſten it, and facilitate its motion: the tears, falling down the *cornea*, are ſtopped by the edge of the under *eye-lid*, along which they run, till they fall into two ſmall holes in the great angle, one in each *eye-lid*, called *puncta lachrymalia*, which lead to a ſmall bag, called *ſaccus lachrymalis*, from the bottom of which a ſmall tube ariſing, called *ductus ad noſum*, opens into the noſe. Between the two *puncta* is a caruncle, or eminence, which ſerves to ſeparate and keep them open, and which was anciently taken for the *glandula lachrymalis*. Near this *caruncula lachrymalis* is ſituated a ſmall ſemilunar membrane, called *tunicula ſemilunaris*, which mutually aſſiſts, and is aſſiſted by the caruncle, in directing the tears to the *puncta lachrymalia*.

The *glandulæ ciliares*, or *glandulæ ſebaceæ Meibomii*, and their orifices, called *puncta ciliaria*, are ſituated in regular rows, parallel to the borders, or internal edges of the *palpebræ*, formed by the *tarſi*, or their cartilages, compoſing the greater part of the edge of each *eye-lid*. The uſe of the ciliary glands is to ſeparate an oily, ſoft fluid; and the uſe of their *foramina*, or *puncta*, is to convey this fluid, when ſecreted, to the ſurface of the internal parts of the *eye-lids*, and to the external ſurfaces of the globes of the *eyes*.

3. The *eye* receives arteries, both from the internal and external carotids, and returns the blood by veins that go to the jugulars.

The muſcles of the eye are ſix: four of which are, from their ſituation, called *recti*, or ſtraight muſcles; and two, *obliqui*. The *recti* come from ſeveral points of the bottom of the orbit, and run immediately between the *ſclerotica* and *adnata*: they derive ſeveral denominations from their ſeveral offices; viz. *attollens*, or *ſuperbus*, which draws the *eye* upwards; *deprimens*, or *humilis*, which calls it down; *adducens*, and *potator*, which draws the *eye* towards the noſe; and *abducens*, or *indignator*, which draws it the other way towards the leſſer angle. The two obliques muſcles are, the *ſuperior*, called alſo *rotator*, and *trochlearis*, and the *inferior*. Theſe muſcles, together with the optic nerve, are ſurrounded by a conſiderable quantity of fat, which makes an eaſy bed for them, and for the whole globe of the *eye*, and thus greatly aſſiſts the muſcles of the *eye* and the *eye* itſelf, in the variety of motions of which they are capable. See each muſcle in its proper place.

The whole ſtructure and apparatus of the *eye* tend to this; that there be produced a diſtinct and vivid collection in the bottom of the *eye*, directly under the pupil, of the rays which, proceeding from any point of an object and entering the *eye*, penetrate the cryſtalline humour; and that ſo many points be painted in the bottom of the *eye* as are conſpicuous in an object, that ſo a ſmall image ſimilar to it may be repreſented on the *retina*.

In order to this, the rays from any radiant or reflecting point ſtriking on the *cornea* are refracted towards the perpendicular, and thus determined to proceed through the aperture of the pupil to the ſurface of the cryſtalline; while other rays, which entered ſo obliquely as to be thrown upon the iris are reflected out again, that they may not diſturb the diſtinctneſs of the ſight; and others, whoſe leſs obliquity threw them between the *uvea* and vitreous humour, are extinguiſhed in the darkneſs thereof, that none may be propagated through the vitreous but ſuch as paſſing through the pupil ſtrike on the cryſtalline.

In the mean time the iris, contracting by its circular, or dilating by its right fibres, the *pupilla* of the *eye* admits fewer or more rays, as the object is nearer or more vivid, or remoter, and more languid. See PUPIL.

Now, the ſtatter the figure of the *cornea* is, the leſs does it collect the rays emitted from any lucid point; whence fewer arrive at the cryſtalline, and thoſe more diverging, unleſs when they come from a very remote object: on the contrary, the rounder it is, the more of the rays from any point does it collect, and throw on the cryſtalline, and thoſe the more converging; whence one great cauſe of the defects in the *eyes* both of old men and myopes. Again, the rays tranſmitted through the pupil to the cryſtalline are there refracted a-new, farther collected, and rendered converging; ſo that thoſe which came from the ſame point of the object are now thrown in one point through the vitreous upon the *retina*, where they paint or exhibit that preciſe point of the object whence they flowed. Accordingly, if the cryſtalline be very denſe or ſpherical, the focus, or the point wherein they are united, will be too near; and if too flat, or rare, the point will be too remote; the effect of both which is confuſion. And hence another cauſe of the defects of myopes and preſbytæ.

It is not, however, myopes and old men alone that would labour under theſe defects, and have their viſion in moſt caſes confuſed, as in objects very near or very remote, very ſmall or very great; but this would be the common condition of viſion. Diſtinct viſion, depending abſolutely on the union of all the rays coming from the ſame point of the object on the ſame preciſe point of the *retina*, and rays from the objects at different diſtances being united at different diſtances behind the cryſtalline: it were impoſſible, e. gr. for the ſame *eye* to ſee diſtinctly any two objects differently diſtant from it: but nature has made a proviſion againſt theſe defects; and that principally by bringing the cryſtalline nearer to the *cornea*, or farther from it, occaſionally; which is effected two ways, viz. either by compelling the bulk of the *eye* by the four muſcles, all ſtrongly contracted at once, which changes the figure of the aqueous humour, and renders the *eye* oblong; or by the *ligamentum ciliare* augmenting and diminiſhing the convexity of the cryſtalline, and ſetting it nearer or farther from the *retina*. As complex as the mechaniſm of the eye may ſeem, and as manifold as the parts are which have a relation thereto, the juſtneſs of viſion ſeems to require an exact habitude in them all: thus, though the pupil be no ſubſtantial part of the *eye*, but only an aperture, the *uvea* almoſt perpetually changing its bignets, according to the different degrees of light the *eye* chances to be expoſed to; and therefore ſhould ſeem, while this hole remains open, to perform its office, by giving entrance to the incident rays of light; yet Mr. Boyle law a woman, who, after a fever, not being able to dilate the *pupillæ* of her *eyes* as before, though they were little narrower than ordinary, yet had the thereby almoſt loſt her ſight; and on the other ſide, though a competent wideneſs of the pupil be requiſite to a clear and diſtinct viſion, yet if its dilatation exceeds the due limits, there is thereby produced a conſiderable diſtemper of ſight. It may ſeem alſo but a ſlight circumſtance that the tranſparent coats of the *eye* ſhould be devoid of colour, and of as little moment that the *cornea* ſhould be very ſmooth, provided it remain tranſparent; yet when either of theſe circumſtances is wanting, the ſight is greatly vitiated. Thus, we ſee that in the yellow jaundice the adventitious colour wherewith the *eye* is tinged makes the patient think he ſees many objects yellow, which are of a contrary colour.

It has been of late an opinion, that though both *eyes* be open, and turned towards an object, yet only one of them, at a time, is effectually employed in giving the repreſentation of it; ſo that the having of the two *eyes* ſhould ſeem in ſome ſort a redundance. But Mr. Boyle furniſhes ſeveral conſiderations which invalidate this opinion, and ſhew that both the *eyes* are of uſe at the ſame time. He aſſures us, he has found by frequent experiment, that his two *eyes* together beheld an object in another ſituation than either of them apart would do: he adds, that he has met with a perſon who had a cataract in his *eye* for two or three years, without finding any impediment in his ſight, though others had, during that time, taken notice of a white film that croſſed his *eye*; till at length happening to rub the ſound *eye*, he was ſurpriſed to find himſelf in the dark; and that a very ingenious perſon, who, by an accident had one of his *eyes* ſtruck out, told him, that for ſome months after he was apt to miſtake the ſituation and diſtance of things; for having frequent occaſion to pour liquors out of one phial into another, after this misfortune, he often ſpilt them, and let them run quite beſide the necks of the phials, which he thought he was pouring them directly into.

The like was related to him by another perſon, who had, by a wound, loſt the uſe of one of his *eyes*, viz. that for ſome time after, he often, in pouring out his wine, miſſed the mouth of the bottle or glaſs.

A yet more conſiderable inſtance of this kind the ſame author gives us of a noble perſon, who, in a fight, had one

of

of his eyes ſtrangely mangled by a muſquet-ball, which came out at his mouth; after which accident he could not well pour drink out of one veſſel into another; but had broken many glaſſes by letting them fall out of his hand, when he thought he had given them to another, or ſet them down on the table: he added, that this aptneſs to miſjudge of diſtances and ſituation continued with him, though not in the ſame degree, for two years. See VISION.

It is no uncommon thing for the *eyes* to be terribly moleſted by extraneous bodies accidentally fallen into them, ſuch as a bit of ſand, a ſplinter of wood, the cutting of a quill, or of one's nails, a ſmall inſect, or the like. The moſt eaſy method of getting theſe bodies out is the opening and extending of the *eye-lid* with one's fingers, and agitating it, holding the head down; by this means the foreign bodies are often waſhed out of the *eyes*, by the increaſed flux of tears, without much difficulty. If this does not ſucceed, the beſt method is next to blow ſome levigated crabs-eyes, or the like fine powder, under the *eye-lids*; that this, being waſhed out by the tears, may carry alſo the other bodies out with it. Heiſter's Surg. p. 364.

The ſeed called *oculus Chriſti*, from its ſuppoſed virtue in clearing the ſight, is very efficacious in ſuch accidents. This it does by its viſcous covering; for when any thing happens to fall into the *eye*, if one of theſe ſeeds is put in at one corner, and the *eye-lid* kept cloſe over it, moving the ſeed gently along the *eye*, whatever happens to be there will ſtick to the ſeed, and ſo be brought out.

If all this fails, the *eye-lid* muſt be gently and carefully lifted up, and the offending body ſought for, and carefully taken out with the end of a probe, or the like inſtrument. Or another method, is the dipping of a fine pencil-bruſh, or a ſmall piece of ſpunge, tied to a ſmall ſtick, into warm water, and paſſing it under the *eye-lid*, and by that means puſhing the offending matter out. Lime, or any other acrid ſubſtance, ſhould always be waſhed out with milk or milk and water, and the *eye* after theſe accidents be waſhed with a collyrium made of roſe-water, with a little of the white of an egg beat up in it, and a ſmall admixture of ſaccharum ſaturni, or powder of tutty; and if there be any conſiderable inflammation, it will be proper to bleed.

It is well known from inſpection, and from the writings of anatomiſts, that there are two veins which run one on each ſide the noſe, through the canthi majores or great corners of the *eyes*: theſe proceed partly from the fore-head, and partly from the *eyes*, and, like the frontal veins, diſcharge their blood down into the external jugular veins. Bleeding in theſe canthal veins has been approved of by all oculiſts for inflammations and other diſorders of the *eyes*, though perhaps with very little ſolid foundation. When this operation is to be performed, a ſtricture is made about the neck; and when the inciſion has been made, the patient muſt hold his head in a proper poſition for the blood to flow, without being troubleſome to his *eye* or mouth; and when the neceſſary quantity of blood has been diſcharged, a thick triangular compreſs muſt be applied, and ſecured on with a proper bandage. Heiſter's Surg. p. 282.

EYES, *running of the*, in *Infants*. See INFANT.

EYES, *ſcarification of the*, is a chirurgical operation, by many contounded with that of bleeding in the *eyes*, but improperly enough, ſince the parts of the operation are different; for bleeding is confined in this organ to the white of the *eye* alone, whereas *ſcarification* is practiſed as well upon the inner ſurface of the *eye-lid* as on the white of the *eye*; and they are alſo performed by different inſtruments.

This is no new operation, ſince Hippocrates, Celſus, &c. all preſcribed it; but of latter ages it grew much into diſuſe.

To perform this operation, the patient is to be ſeated in a good light, and his head held ſtill by an aſſiſtant, while the ſurgeon preſſes his thumb and fore-finger on the *eye-lids*, ſo as to open them and turn them outward, that their interior red ſurface may come into view: this is much more conveniently performed on the under than on the upper *eye-lid*. When the ſurface is thus turned up, the ſurgeon draws the ſcarifying inſtrument backward and forward over it with great ſwiftneſs, as alſo over the white of the *eye* if there be occaſion, and by this means opens all the turgid veſſels, and makes them bleed plentifully: this ſhould be promoted by fomenting the *eye* with a ſpunge dipped in warm water. Heiſter's Surgery, p. 401.

When the operation is over, great care is to be taken that the wounded parts do not cohere together; the patient muſt move the *eye-lids* about at times to prevent this; and the *eye* when bound up at night muſt have a piece of gold-beater's ſkin applied between the *eye-lids* and the *eye*.

Many different inſtruments have been uſed for making the *ſcarification*. Hippocrates uſed a prickle of a thiſtle, and Celſus and Ægineta a ſmall raſp. Others have choſen the ſtalks of the naked horſe-tail, called ſhave graſs, which do very well; but the beſt of all inſtruments is a beard of barley or rye; theſe beards are furniſhed with rows of ſharp teeth or hooks, and ten, twelve, or fifteen of theſe are to be cut and tied together by a ſtring, ſo as to reſemble a bruſh, the teeth of each beard being turned outward all round: their ſlender ends in this caſe form a ſort of handle, by which the body of the bruſh may be moved about.

EYE, *contuſion of the*. When the eye is by any accident contuſed, it will be entirely deprived of ſight, unleſs the contuſion be ſlight, or the proper remedies inſtantly applied. If the *eye* have received a very ſlight contuſion, it will be proper to waſh it frequently for the firſt day with cold ſpring-water, laying on it linen rags, wet with the ſame: on the next day it muſt be rubbed externally with camphorated ſpirit of wine, and covered up with ſtupes wrung out of decoctions made in wine, of *eye bright*, ſpeed-well, hyſſop, ſage, chamomile-flowers, and fennel-ſeeds; but if theſe things are not to be had, boſſters dipped in warm wine muſt be applied, and renewed very often; and if the patient be of a plethoric habit, bleeding is alſo neceſſary. If the contuſion of the *eye* is ſo violent that you can plainly ſee the extravaſated blood through the cornea, and all objects appear red to the patient, a vein muſt be either opened in the foot or neck; the *eye* muſt be kept continually fomented with warm ſtupes, wrung out of the ſame decoctions as are before mentioned, and the feet muſt be bathed in warm water two or three times a day, and a few drops of pigeons blood muſt be two or three times a day poured into the *eye*; and if all theſe attempts prove fruitleſs, you may very probably ſucceed by making an opening in the cornea with a lancet. Heiſter's Surgery, p. 110.

EYE, *wounds of the*. If the *eye* is wounded, but not ſo as to let out the vitreous or cryſtalline humour, the wound muſt be anointed two or three times a day with a feather or fine rag well dipped in the white of an egg, or elſe in a mucilage made of quince-ſeeds, or of ſtarwort-ſeeds, in roſe-water; and after each dreſſing a compreſs is to be laid on, well faturated with a collyrium made of the whites of eggs, two ounces and a half of roſe-water, half a dram of oil of roſes, and three grains of camphor, well mixed together, and thoroughly ſhook up every time it is to be uſed. If the accident is attended with any great degree of inflammation, as is very frequently the caſe, it will be proper to cover the ſmall compreſs, firſt laid over the *eye*, with a larger, dipped in warm ſpirits of wine, with camphor. The bowels muſt in this caſe be kept open, and the patient blooded, if of a plethoric habit; and if it happen that the cryſtalline humour, or any part of it, ſticks in the orifice of the wound, it muſt in this caſe be pulled out, that it may not bring on a deformity or worſe miſchief to the *eye*. Heiſter's Surgery, p. 90.

EYE, *falling out of the*. See PROLAPSUS *oculi*.

EYE, *diſeaſes of the*, are an ophthalmia, or inflammation of the *eyes*; the gutta ſerena, or amaurooſis; a ſuffuſion, or cataract; an ectropium; a glaucoma; an amblyopia, or obſcurity of ſight, including the myopia, the preſbytopia, the nyctalopia, and the amaurooſis; the ſtrabiſmus, or ſquinting; an unguis pannus, or pterygium of the membrane of the *eye*; the albugo, leucoma, or ſpot in the *eye*; a fugillation of the *eye*; an epiphora, or rheum in the *eyes*; a trichiaſis; and the fiſtula lachrymalis. See each deſcribed under its peculiar denomination. See Warner's Deſcription of the Human *Eye*, &c. with its principal Diſeaſes, &c. 2d edit. 1775.

The comparative ſtructure and anatomy of the *eye* is very curious; the ſituation, number, conformation, &c. of this organ in different animals, being finely and wonderfully adapted to their different circumſtances, occaſions, and manners of living.

In man, and ſome other creatures, an ingenious author obſerves, the *eye* is placed chiefly to look forward; but withal is ſo ordered as to take in nearly the hemiſphere before it. In birds, and ſome other creatures, the *eyes* are ſo ſeated as to take in near a whole ſphere, that they may the better ſeek their food and eſcape danger. In others they are ſeated ſo as to ſee behind them, or on each ſide, whereby to ſee the enemy purſuing them: thus, in hares and conies, the *eyes* are very protuberant, and placed ſo much towards the ſide of the head, that their two *eyes* take in nearly a whole ſphere; whereas in dogs that purſue them, the *eyes* are ſet more forward in the head, to look that way more than backward.

Generally, the head is contrived to turn this and that

way

way chiefly for the occaſions of the eyes; and generally the *eyes* themſelves are moveable upwards, downwards, backwards, and ſidewiſe, for the more commodious reception of the viſual rays. Where nature deviates from theſe methods, ſhe always makes uſe of very artful expedients to anſwer the ſame end.

Thus, in ſome creatures, the *eyes* are ſet out at a diſtance from the head, to be moved here and there, the one this way, and other that; as in ſnails, particularly, whoſe *eyes* are contained in their four protuberances, like ornamentous ſpots fitted to the ends of their horns, or rather to the ends of thoſe black filaments or optic nerves ſheathed in the horn. Power, Exper. Phil. Obſ. 31.

And in other creatures, whoſe *eyes* or head are without motion, and in divers inſects, that defect is ſometimes made up by their having more *eyes* than two; as in ſpiders, which having no neck, and conſequently the head being immoveable, the defect is ſupplied by the ſituation and multiplicity of their *eyes*; ſome having four, ſome ſix, and others eight, all placed in the fore-front of their head, which is round, like a locket of diamonds. The reaſon Dr. Power gives, is, that being to live by catching ſo nimble and ſhy a prey as flies, they ought to ſee every way, and ſo take them *per ſaltum*, without any motion of the head to diſcover them.

Again, men, and moſt quadrupeds, are found to have ſeveral muſcles belonging to their *eyes*, by help whereof they can turn them any way, and ſo obvert the organ of ſenſe to the object. But nature not having given that mobility to the *eyes* of flies, ſhe in recompence furniſhes them with a multitude of little protuberant parts, finely ranged upon the convex of their large bulging *eyes*; ſo that by means of theſe numerous little ſtuds numberleſs rays of light are deflected from objects placed on either hand, above or beneath the level of the *eye*, and conveniently thrown upon that organ, to render the objects they come from viſible to the animal; and by the help of a good microſcope, and a clear light, ſome hundreds of theſe little round protuberances may be diſcovered, curiouſly ranged on the convexity of a ſingle *eye* of an ordinary fleſh-fly.

So ſcorpions are found to have above a hundred eyes; and Swammerdam has obſerved no leſs than two thouſand in the little inſect called *ephemeron*.

In other creatures the like deficiency is ſupplied by having their *eyes* nearly two protuberant hemiſpheres each conſiſting of a prodigious number of other little ſegments of a ſphere.

The *eyes* of a cameleon, Dr. Goddard obſerves, reſemble a lens, or convex-glaſs, ſet in a verſatile globular ſocket, which he turns backward and forward without ſtirring the head, and ordinarily the one a contrary way to the other.

Laſtly, the mole, which the ancients, Ariſtotle, Pliny, Alb. Magnus, &c. ſuppoſed to have no *eyes* at all, is now found to furniſh a notable inſtance of the diverſity of the apparatus of viſion; for that animal living altogether under ground, light would generally be uſeleſs to it, and ſo tender a part as the *eye* troubleſome. It has therefore *eyes*, but thoſe ſo exceedingly ſmall, and withal ſituated ſo far in the head, and covered ſo ſtrongly over with hair, that they cannot ordinarily be of ſervice or diſſervice to it. Yet, to guide and ſecure it a little when it chances to be above-ground, Borrichius, Blaſius, Schneider, Dr. Derham, and others, obſerve that it can protend, or put them forth beyond the ſkin, and again draw them back at pleaſure, ſomewhat after the manner of ſnails.

In the *eyes* of nocturnal animals is a part not yet mentioned, viz a ſort of tapetum at the bottom of the *eye*, which gives a kind of radiation on the pupil, enabling them to ſee and catch their prey in the dark. Thus, Dr. Willis, *Hujus uſus eſt oculi pupillam quaſi jubare inſito illuminare—quare in fele plurimum illuſtris eſt; at homini, avibus & piſcibus deeſt.* De Anima Brutor.

He adds, that in ſome perſons the iris has a faculty alſo of darting out light; and inſtances in a man of a hot head who, after a plentiful drinking of generous wine, could ſee to read in the darkeſt night. Ibid.

The like Pliny tells us of Tib. Cæſar, that upon his firſt waking in the night he could ſee every thing for a little while as if in broad day-light. Nat. Hiſt. lib. xi. cap. 37. and Dr. Briggs gives a parallel inſtance of a gentleman in Bedfordſhire. Opthal. cap. v. §. 12.

Frogs, beſides the parts of the *eye* which they have in common with men, and moſt quadrupeds, have a peculiar membrane or cartilage, which is not commonly perceived, wherewith they can at pleaſure cover the *eye* without too much hindering the ſight; becauſe the membrane is both tranſparent and ſtrong, ſo that it may paſs for a kind of moveable cornea, or occaſional ſafeguard to the *eye*. A like membrane is alſo found in many birds, as alſo in the crocodile.

Naturaliſts relate wonders of the ſharpneſs and accuracy of the *eye* of ſome animals, as the eagle, &c. beyond thoſe of men.

Yet do thoſe of men ſeem improveable to a ſurpriſing degree. Mr. Boyle inſtances in a major of a regiment of king Charles I. who being afterwards forced abroad, ventured at Madrid to do his king a piece of ſervice of an extraordinary nature and conſequence; which being there judged very irregular, he was committed to an uncommon priſon or rather dungeon, having no window belonging to it, only a hole in the wall, at which the keeper put in proviſions, and preſently cloſed it again on the outſide, but not perhaps very exactly. For ſome weeks this gentleman continued utterly in the dark, very diſconſolate; but afterwards he began to think he ſaw ſome little glimmering of light; and this from time to time increaſed ſo, that he could not only diſcover the parts of his bed, and other ſuch large objects, but at length, amidſt this deep obſcurity, could perceive the mice that frequented his chamber to eat the crumbs of bread which fell upon the ground, and diſcern their motions very well.

The author juſt mentioned, in his Obſervations on Vitiated Sight, gives us ſome uncommon phenomena that regard the *eyes*. He furniſhes ſeveral inſtances of nyctalopies, or people whoſe *eyes* in the day-time were quite dark, or at leaſt ſo dim that they could hardly diſcern their way; who yet, ſoon after ſun-ſet, and during twilight, ſaw very clearly.

EYES *of fiſh.* Theſe differ ſo much in their ſeveral kinds, that they make a very eſſential part in their deſcription, and often are characters ſufficient for diſtinguiſhing the ſpecies. Their differences are in regard to their figure, ſituation, proportion, and integuments. In regard to their figure, ſome are flat and depreſſed, as is the caſe in the greater number of fiſhes. 2. Some are convex, as in the caſe of the plearonecti of many kinds: the *eyes* of theſe much reſemble thoſe of quadrupeds, the others are very different. 3. Some are rounder than ordinary, as in the cyprini, [illegible] perromyzon; and laſtly, ſome are oblong, [illegible] the cloces.

Theſe are the differences of [illegible] fiſh as to figure: in regard to their ſituation they differ as much: 1. In moſt fiſh they are placed in the ſides of the head; inſtances of this poſition are ſufficiently common. 2. In ſome they are placed both in the upper part of the head, as in the uranoſcope, or ſtar-gazer. 3. They are in ſome placed very cloſe to one another, as in the pleuronecti; and in others they are ſet at very remarkable diſtances, as in the clariæ. They differ alſo greatly in proportion, in reſpect to the body of the fiſh. Thus they are very ſmall in the whales, and other cetaceous fiſhes; and they are as remarkably large in the opas, boops, and galteroſteus.

The *eyes* in fiſh differ alſo greatly in regard to their integuments. In ſome fiſh they are free, and are only covered with their proper membranes, as in the ſalmon, cyprini, &c. 2. They are in ſome covered in part with the ſkin of the head, as in the clupea, mackrel, &c. 3. In ſome they are wholly covered with the ſkin of the head as with a ſort of veil. Examples of this kind there are in the ſyngnathi, pleuronecti, petromyzn, and others. The pupil of the *eye* is in moſt kinds of fiſh either round or oblong; but in ſome, as in the ſalmons and coregones, they run out into an acute angle in the anterior part. The colour of the iris in ſeveral fiſh is ſo very diſtinct that it makes a very obvious and diſtinctive character.

The *eyes* of almoſt all fiſh are without eye-lids, properly ſo called; but ſeveral kinds have, beſide the membranes and common tunics, a ſort of tranſparent membrane, with which the *eye* is in part at times covered. The cetaceous fiſhes, in particular, ſeem to have real eyelids: Tyſon has demonſtrated them in his accurate and excellent anatomy of the phocena.

It is obſerved by Mr. Baker, that if the *eyes* of fiſh are carefully examined when ſwimming in a glaſs veſſel, the cornea or black uvea may be ſeen, ſometimes advancing forwards, and at other times retiring back, juſt as their ſight is directed to near or diſtant objects, through a groſſer or finer medium; the form of their *eyes* altering as occaſion requires to make them diſtinct objects; and their *eyes* have ſo great a liberty in the orbits, that they are able to turn them any way, upwards, downwards, to one ſide or the other, nearly a quarter of a circle, which makes them full amends for the want of motion in their necks, and enables them to change the direction of their optic axis to any aſſigned place in a moment. Phil. Tranſ. vol. xiv. p. 153.

EYES *of flies.* Every naturaliſt has obſerved, that, the *eyes* of flies are of a reticulated texture; and each reticulated *eye* of this kind is truly an aſſemblage of multitudes, often

often of many thousands, of small but perfect *eyes*. The reticulated *eyes* of flies are large, not only in proportion to the size of the creature, but absolutely, and in themselves; but the several small *eyes* of which they are composed are remarkably minute in comparison of those of the butterfly claſs.

Many of the butterfly claſs have in each of their reticulated *eyes* many thousand small *eyes*; but the fly claſs greatly exceed them in number of theſe, as many of the *eyes* of theſe are three times as large as thoſe of the butterflies; and beſides, that each ſmaller *eye* is vaſtly more minute than the ſmall *eyes* of the butterflies.

Dr. Hook computed 14,000 hemiſpheres in the two *eyes* of a drone; Mr. Leewenhoeck reckoned 6236 in a ſilk-worm's two *eyes* in its fly ſtate; 3181 in each eye of a beetle; and 8000 in the two *eyes* of a common fly. The pearl-*eyes* of the DRAGON-*fly* appear with a common reading-glaſs like ſhagreen; and Mr. Leewenhoeck reckons in each *eye* of this inſect 12,544 lenſes, placed in an hexangular poſition, each lens having ſix others round it. He alſo obſerved in the centre of each lens a minute tranſparent ſpot, brighter than the reſt, ſuppoſed to be the pupil, ſurrounded with three circles, and in appearance ſeven times leſs than the diameter of the whole lens. Mr. Puget counted 17,325 in the *eye* of a butterfly, which Malpighi concludes to be diſtinct and ſeparate *eyes*. The abbé Catalan, and others, have ſince ſhewn, that all the eminences diſcoverable in the cornea of inſects have the neceſſary parts, and perform the offices of an *eye*. Leewenhoeck diſcovered the buddles of optic nerves which ſerve theſe ſmall lenſes; and Reaumur ſuppoſes that theſe ſupply the place of all that is wanting behind the lenſes, for the organization of an *eye* complete for viſion. Baker's Micr. 1743, p. 228. Reaumur, Hiſt. Inſ. vol. i. p. 261, &c.

That part of each ſide of the head of a fly which is cut, as it were, into a multitude of ſmall facets, is one of the reticulated *eyes* of the creature, and is uſually ſomewhat elevated above the ſurface of the reſt of the head, but differently, and of a different form and extent in the ſeveral different flies. Ibid. Vol. iv. p. 239.

It is the cuſtom of nature to allot two of theſe reticulated *eyes* to each fly; and as they each contain ſuch a vaſt multitude of ſmaller, but perfect *eyes*, one would imagine this to be very ſufficient for all the occaſions of the animal. There are, however, notwithſtanding, certain flies of the ephemeron or day-fly kind, which have four of theſe reticulated *eyes*, two of which are placed as is uſual in the fly kind, and are but of ſmall extent; the other two have each the appearance of a ſort of turban, and are placed one beſide the other upon the upper part of the head.

Theſe have each much of the figure of a muſhroom, the head of it extended a little beyond the ſtalk, and the upper convex ſurface cut into almoſt an innumerable quantity of facets. Id. ibid. p. 240.

The firſt pair of the reticular *eyes* of this fly which are placed as thoſe of the other flies, are in colour brown; thoſe of the muſhroom form are of a very beautiful citron colour, and as tranſparent as the moſt pellucid reticular *eyes* of the other flies; for, among the various ſpecies of flies, ſome have theſe *eyes* much more tranſparent than others.

The fly thus remarkably furniſhed with *eyes* is produced from a worm of the ſame kind with the common ſpecies of ephemerons; its body is of a pale yellow, and its wings white; the two inferior ones of theſe are ſo ſmall that they are not eaſily diſtinguiſhed.

Among the fly claſs theſe reticular *eyes* are in different ſpecies of different colours; there are ſome which have them brown, others yellow, others green, and others red, and this in all the different ſhades of thoſe colours.

Some of them have alſo the gloſs of metals highly poliſhed, others afford us a view of changeable colours, and others have arrangements of different colours, but thoſe fixed and invariable. Id. ibid. p. 241.

The *eyes* of one ſpecies of the gad-fly, ſo troubleſome to oxen, have ſtreaks of red, green, and brown, placed alternately.

One would imagine, that as every fly has two of theſe reticular *eyes*, each compoſed of ſuch a multitude of real *eyes*, they could have no occaſion for any *eyes* beſide theſe; but ſo it has not appeared to the great being that formed them, for they have, many ſpecies of them at leaſt, other *eyes* beſide theſe.

The *eyes* already deſcribed are properly called reticular ones; and to avoid confuſion, it will be neceſſary to know the other *eyes*, which are extremely different from thoſe, by ſome determinate name. Theſe other *eyes*, when examined by the beſt microſcopes, appear of a perfectly ſmooth, gloſſy, and poliſhed ſurface, but plain and ſimple, without the leaſt appearance of a reticulated texture. Theſe are alſo much ſmaller than the reticulated *eyes*, and may therefore be called, by way of diſtinction, the ſmaller *eyes*, or the ſmooth *eyes*.

M. De la Hire ſeems to have been the firſt perſon who diſcovered theſe little ſmooth *eyes* in the fly race. He obſerved three of them diſpoſed in a triangular form, on the back part of the heads of theſe little creatures. When he found that three ſmall convex ſhining bodies were uſually ſituated in this part, he ſoon diſcovered that they were tranſparent, and thence naturally judged them to be of the ſame nature of the corneæ of our *eyes*, and really to ſerve the ſame office to the creature poſſeſſed of them.

We find three of theſe ſmooth *eyes* placed triangularly on the back part of the head of vaſt numbers of the genera of flies, as well of the two-winged as of the four-winged kinds; but there are alſo ſome flies of both theſe claſſes in which they are wanting.

All the ſpecies of gnats, and all the ſpecies of tipulæ, are without theſe ſmooth *eyes*. The heads of theſe ſpecies of flies are very ſmall in proportion to the bulk of their body, and are in a manner covered with their reticular *eyes*, which in ſuch a manner meet and touch one another, as to leave no room nor occaſion for the ſmooth *eyes*.

Theſe flies have the want of their ſmall *eyes* amply made up by the ſize and extent of the larger; but there are ſome other kinds which want them, without having this advantage in their place. Of the two winged flies with ſhort bodies, the gad-flies want theſe *eyes*; and among the longer bodied and four-winged kinds, the flies produced from the puceron-eaters want them.

Notwithſtanding, therefore, that many ſpecies of flies have theſe *eyes*, there are yet ſo many that want them, that, if M. De la Hire's opinion, that the reticulated *eyes* of flies were not true *eyes*, held good, there muſt be very many of theſe inſects blind.

Though moſt of the flies that have theſe *eyes* have three of them, and thoſe triangularly placed, yet there are ſome that have more, and ſome that have leſs than that number. A certain fly which has two filaments attached to the hinder part of its body, and its hinder pair of legs faſtened to the annular portion of its body, has four of theſe ſmooth *eyes* placed at the four corners of a ſquare; the two anterior tolerably large, and the two poſterior ſo ſmall as to be ſcarce diſtinguiſhable. And other flies, as the papilionaceous ones, produced of water-worms, have only two of them. Ibid.

The poſition of theſe *eyes* varies alſo in the different ſpecies of flies which are poſſeſſed of them; for though their uſual place is in the hinder part of the head, there are ſome which have them before. Some ſpecies of the ephemerons have three of theſe *eyes*, which may be called large in regard to their uſual ſize in other flies. The one of theſe is placed in the middle of the forehead; the other two at the roots of the antennæ, placed ſideways by them, but a little more backward. This ſpecies has two reticular *eyes* beſide theſe, but they are ſmaller than is uſual in that ſpecies of fly.

Theſe *eyes* are not peculiar to the fly claſs alone, ſome other of the inſects which have reticular *eyes* have theſe alſo, among which are the graſshopper, in which they are placed near the noſe.

Notwithſtanding that theſe *eyes* are not well diſtinguiſhed in flies without the aſſiſtance of glaſſes, they may, however, ſerve very well for the diſtinctions of genera among thoſe ſpecies which have them. Id. ibid. p. 245.

Theſe *eyes*, though very ſmall in themſelves, yet, in compariſon with the ſingle *eyes*, which form the reticular ſort, they are very large. See INSECT.

EYES *of horſes*, in the *Manage*, &c. Theſe ſhould be bright, lively, full of fire, pretty large, and full; but not too big, goggling, or ſtaring out of the head: they ſhould alſo be reſolute, bold, and brisk. A horſe, to appear well, ſhould look on his object freely, with a kind of diſdain, and not turn his *eyes* another way.

In the *eye* of a horſe are diſcovered his inclination, health, and diſpoſition. When the *eyes* are ſunk, or the *eye-brows* are too much raiſed up, and as it were ſwelled, it is a ſign of vicioufneſs and ill nature. When the pits above the *eyes* are extremely hollow, it is for the moſt part a certain ſign of old age: this, however, does not hold of horſes got by an old ſtallion; for theſe have them very deep at the age of four or five years, as alſo their *eye-hair* and *eye-brows* wrinkled and hollow.

Two things are chiefly to be conſidered in the *eye* of a horſe, viz. the cryſtalline part, and the bottom or ground. The cryſtalline, or moſt tranſparent part, ſhould, for clearneſs, reſemble a piece of rock-cryſtal, otherwiſe the *eye* cannot be good. When this part is reddiſh it is a ſign that the *eye* is inflamed, or elſe, as ſome pretend, influenced by the moon. When it is of the colour of a

withered or dead leaf upon the lower part, and troubled on the upper, it infallibly ſhews that the horſe is lunatic, which diſtemper continues no longer than while the humour actually poſſeſſes the *eye*.

As to the ground or bottom of the *eye*, which is properly its pupil or apple, it ſhould be large and full, and ought to be carefully inſpected, that there be no *dragon*, as it is called, on it. This is a white ſpot or ſpeck, which at firſt appears no bigger than a grain of millet, but grows to ſuch a bigneſs as to cover the whole apple of the *eye*: it is incurable, never failing to make a horſe blind in the *eye* where it is found. If the whole bottom of the *eye* be white, or of a tranſparent greeniſh white, it is a bad indication, though perhaps the horſe is not as yet quite blind: however, it ought to be obſerved, that if you view a horſe's *eyes* when oppoſite to a white wall, the reflection of it will make thoſe apples appear whiteiſh, ſometimes inclining to green, though they be really good. When this is perceived, you may try whether his *eyes* have the ſame appearance in another place.

In caſe you perceive above the bottom of the *eye*, as it were, two grains of chimney-ſoot fixed thereto, it is a ſign the cryſtalline is tranſparent; and if, beſides this, the ſaid bottom be without a ſpot or whiteneſs, then you may infer that the *eye* is ſound.

You ought alſo to examine whether an *eye* which is troubled and very brown be leſs than the other; for if it be, it is irrecoverably loſt.

All *eyes* which are ſmall, narrow, and have long pupils, run a greater riſk of loſing the ſight than any others. See BLINDNESS.

The diſeaſes of the *eyes* in horſes, proceed either from a defluxion, or from ſome external hurt. In the former caſe the *eyes* are watery, hot, red, and ſwollen, the diſtemper advancing by degrees; in the latter the malady comes ſpeedily to a height, and the ſkin on the outſide of the *eye* is peeled off.

If the diſtemper takes its riſe from a rheum or defluxion, it is to be conſidered whether it proceeds from the *eye* itſelf, or from another aggrieved part: in the latter caſe, the redreſſing of the part will let the *eye* free; in the former, it is proper to cool the horſe's blood with an ounce of ſal prunellæ, mingled every day with his bran; and when it leſſens his appetite, to change it for liver of antimony, till he recovers his ſtomach.

For ſore *eyes*, where a ſkin is growing over them, the following receipt is recommended: to the white of an egg add a little fine powdered ſalt; then ſet this on the fire till it be reduced to a powder. This mixed with a little honey, is to be put into the horſe's *eye* with a feather. If it is found inſufficient to eat off the ſkin, the powder alone muſt be blown into the *eye* with a quill.

In caſe of a blow on the *eye*, take honey; and having added a ſmall quantity of powder of ginger, put it into the horſe's *eye*; or elſe take hog's lard, with the oil of roſes and elder, of each an equal quantity; then, having melted them together, anoint the *eye* therewith.

Some horſes have naturally rheumy weeping *eyes*, which void a ſharp eating humour; theſe are eaſily cured, by waſhing or bathing them every morning or evening with brandy. See HORSE.

We ſay alſo, *a horſe wanting one eye*, which is a rallying expreſſion, importing that he is blind of an *eye*.

EYE *of the branch of a bridle*, in the *Manege*, is the uppermoſt part of the branch which is flat, with a hole in it, for joining the branch to the head-ſtall, and forkeeping the curb faſt.

EYE *of a boar*, in the *Manege*, is a black ſpeck or mark in the cavity of the corner-teeth, which is formed there about the age of five and a half, and continues till ſeven or eight; and it is from hence that we uſually ſay, ſuch a horſe marks ſtill, and ſuch a one has no mark.

EYE, *artificial*, is an optical machine, wherein objects are repreſented after the ſame manner as in the natural *eye*, of conſiderable uſe in illuſtrating the nature and manner of viſion.

Its conſtruction is thus: provide two hollow hemiſpheres of hard, dry wood, well cemented together, to repreſent the ball of the *eye*; let the interior or fore-hemiſphere be perforated with a round hole in C (*Tab. Optics, fig.* 9. *n.* 2.) to ſupply the place of a pupil, and therein fit a thin, plain glaſs, or, which amounts to the ſame, a concavo-convex glaſs, to ſerve for the cornea. In the inſide put a ſhort draw-tube G, with a lens convex on both ſides, to do the office of the cryſtalline therein. In the hind, or poſterior hemiſphere, fit another draw-tube E F, with a plain glaſs therein, having its inner ſurface ſmooth, though not poliſhed, repreſenting the retina and optic nerve.

If now the aperture C be turned towards any object, and the draw-tube F E be gradually pulled out, you will have the object beautifully and ſtrongly repreſented in all its colours on the retina, only in an inverted order. See VISION.

It being of no conſequence what the figure of the inner cavity is; any room or chamber ſo darkened as only to receive light from a ſingle hole, with a glaſs convex on both ſides fitted therein, will do the office of an *artificial eye*, and exhibit all the objects oppoſed to the aperture on a wall or a white cloth ſtretched at a proper diſtance from the aperture, with this circumſtance, that the leſs ſphere the glaſs is a fragment of, the larger will the figures appear; and this is the celebrated *camera obſcura*. See CAMERA *obſcura*.

EYE *in perſpective*. See PERSPECTIVE.

EYE, *attitude of the*. See ATTITUDE.

EYE, in *Architecture*, is uſed for any round window made in a pediment, an Attic, the reins of a vault, or the like.

EYE, *bull's*, *Oeil de bœuf*, denotes a little ſky-light in the covering or roof, intended to illumine a granary, or the like.

The ſame term is applied to the little lutherns in a dome; as in that of St. Peter's at Rome, which has forty-eight in three rows. See LUTHERN.

EYE *of a dome*, denotes an aperture at the top of the dome; as that of the Pantheon at Rome, or of St. Paul's at London. It is uſually covered with a lantern.

EYE *of the volute*, in *Architecture*, is the centre of the volute, or that point wherein the helix or ſpiral whereof it is formed, commences; or, it is the little circle in the middle of the volute, wherein are found the thirteen centres for deſcribing the circumvolutions thereof. See *Tab. Archit. fig.* 30. and *fig.* 29. See alſo VOLUTE.

EYE-*ſtaps*, thoſe pieces of leather which cover the *eyes* of coach-horſes.

EYE, in *Agriculture* and *Gardening*, denotes a little bud or ſhoot inſerted into a tree by way of GRAFT.

The term *eye*, *oculus*, is alſo uſed for a gem or bud, as it ſtands on the parent tree. See BUD and PRUNING.

EYE *of a pear*, the extremity oppoſite to its ſtalk. See PEAR.

EYE *of a tree*, a ſmall point [illegible] in which the leaves ſtick, and from which the ſhoots or ſprigs proceed.

EYE, in a *Ship*. The hole wherein the ring of the anchor is put into the ſtock is called the *eye of the anchor*; and the compaſs or ring which is let of the ſtrap to which any block is ſeized is called the *eye of the ſtrap*.

EYE *of the ſtay*, is that part of a ſtay which is formed into a ſort of collar to go round the maſt-head.

EYE-*bolt*, is a long bar of iron with an *eye* in one end of it formed to be driven into the decks or ſides of a ſhip for divers purpoſes, as to hook tackles, or faſten ropes to, as occaſion requires.

EYE-*let-hole*. See SAIL.

EYES *of a ſhip*, a name frequently given to thoſe parts which lie near the hauſe-holes, particularly in the lower apartments within the veſſel.

EYE-*bright*, in *Botany*, *euphraſia*, a genus of the *didynamia angioſpermia* claſs. This is a medicinal plant which grows naturally in ſterile fields and commons in moſt parts of England. Its characters are theſe: the flower is of the perſonated kind, divided into two lips, and having the upper one placed erect, and divided into ſeveral ſegments; the lower one divided into three principal ſegments, each of which is alſo bifid; the piſtil ariſes from the cup, and is fixed in the manner of a nail to the back part of the flower, this finally ripens into a capſule of an oblong ſhape, containing ſmall ſeeds. There are two ſpecies. Tourn. Inſt. 174. Linnæus enumerates ſeven ſpecies.

Theſe plants always grow among heath, furze, graſs, or ſome other cover, nor will they grow when theſe are cleared from about it, nor when ſown in a garden. The herb-women ſupply the markets with it in plenty from the fields.

Eye-bright is much recommended in diſorders of the *eyes*, eſpecially weakneſs and dimneſs of ſight. It is given in ſeveral forms, but the powder of its leaves is thought moſt effectual as well as ſafeſt, the doſe being from one to three drams.

EYE, among *Naturaliſts*, is ſometimes alſo uſed for a hole or aperture: wherein it is that the firſt of the larger inteſtines is called *cæcum*, or the *blind gut*, as having no *eye* or perforation. For a like reaſon the chemiſts call a cloſe veſſel uſed in diſtillation, a *blind head*.

EYE, in *Printing*, is ſometimes uſed for the thickneſs of the types and characters uſed in printing; or moſt ſtrictly, it is the graving in relievo on the top of the letter; otherwiſe called its *face*.

It is the *eye* or *face* that makes the impreſſion; the reſt, which they call the *body*, ſerving only to ſuſtain it.

The *eye* of the *e* is the little aperture at the head of that character, which diſtinguiſhes it from the *c*. See E.

EYE is alſo uſed among Jewellers for the luſtre and brilliance

liance of pearls and precious ſtones, more uſually called the *water*.

EYE-*brews, wounded*. In wounds of this part great care muſt be taken to guard againſt inflammations, leſt the *eyes* ſhould partake of the injury; all hot and ſharp things muſt be avoided in eating and drinking; and the patient ſhould be blooded if plethoric; the wound muſt be dreſſed with vulnerary balſams, and the dreſſings covered with compreſſes dipped in camphorated ſpirit of wine. If the wound be large, and the *eye-brow* entirely divided, it will be neceſſary to uſe the future and dreſs over it with a vulnerary balſam, covering both *eyes*, and keeping them as much as poſſible from motion. Heiſter's Surg. p. 79.

EYE-*brow*, in *Architecture*. See FILLET.

EYE-*lids, palpebræ*, in *Anatomy*, thoſe external moveable covers which ſerve to ſcreen and defend the *eyes*.

They conſiſt of a thin muſcular membrane, covered on the outſide with a ſtrong, yet flexible ſkin, and lined within-ſide with a production, as ſome think, of the pericranium. Their edges are fortified with a ſoft cartilage, by means whereof they are enabled to cloſe the better.

Out of theſe cartilages grow a paliſade of ſtiff hairs, called *cilia*, of great uſe to warn the *eye* of the approach of danger, either in ſleeping or waking; to keep off motes, flies, &c. in the air, and to break the too fierce impreſſion of the rays of light.

Theſe hairs, it is obſerved, only grow to a certain convenient length, and never need cutting, as moſt others do; add to this, that their points ſtand out of the way; thoſe of the upper *eye-lid*, being bent upwards, as thoſe of the lower downwards, ſo nice is nature in ſuch ſmall matters.

At the commiſſure, or joining of the upper and under *eye-lids*, are formed two angles called *cantbi*.

In the inner ſurface of the *eye-lid*, ſerve to moiſten the ball of the *eye*, and keep its membrance from growing harſh and dry.

Near the other angle lies a gland called *innominata*, which helping alſo by ſeveral branches to irrigate the *eye*, the overplus is carried to the greater angle, and tranſmitted to the noſe through the puncta lachrymalia.

By theſe glands it is that the humour, called tears, is ſecreted.

The *eye-lids* are both moveable, eſpecially the upper, which has two muſcles to raiſe and depreſs it, called *attollens* and *deprimens*, or *orbicularis*. See ATTOLLENS and ORBICULARIS.

Its quadruped is the lower *palpebra* is moveable, and is the ſmaller; in birds, on the contrary, the lower is moveable, and the greater.

Animals that have hard *eyes*, as lobſters, and the generality of fiſhes, have no *palpebræ*, ſuch eyes being ſufficiently ſecured without.

In the generality of brutes there is a kind of third *eye-lid*, which is drawn like a curtain, to wipe off the humidity which might incommode the *eye*; it is called the *nictitating membrane*.

The monkey is almoſt the only one that wants it, as being furniſhed, like a man, with hands to wipe the *eye* on occaſion.

EYE-*lids wounded*. Wounds, either of the upper or lower *eye-lid*, will not readily heal, not ſo much from the thinneſs of the parts as from the great quantity of fluids with which the *eye* is continually moiſtened. It is neceſſary, therefore, firſt to foment the part with decoctions of chamomile, hyſſop, or eyebright, till the flux of the blood is ſtopped, and the wound well cleanſed; then if the wound is tranſverſe, it muſt be ſtitched up in the middle with a fine needle, and ſprinkled over afterwards with the powder of comfrey-root, gum-arabic, or other ſuch medicines, or anointed with balm of Gilead, or Peru, or Capivi, laying over theſe applications a plaſter of diachylon, and tying it up in ſuch a manner that the *eye* may have very little power to move about. If the wound is made lengthways it will require ſeveral ſtitches, and muſt be dreſſed over them as before. Heiſter's Surgery, p. 79.

EYE-*glaſs*, in our *Double Microſcopes*, is uſually a lens convex on both ſides; but Euſtachia Divini long ſince invented a microſcope of this kind, the power of which he places very greatly above that of the common ſort; and this principally depending on the *eye-glaſs*, which was double, conſiſting of two plano-convex glaſſes, ſo placed as to touch one another in the middle of their convex ſurface. This inſtrument is ſpoken of with great credit by Fabri in his Optics, and is ſaid to have this peculiar excellence, that it ſhews all the objects flat, and not crooked, and takes in a large area, though it magnifies extremely much. Phil. Tranſ. N° 40.

EYE-*ſucker*, in *Natural Hiſtory*, a ſmall ſea-inſect, which is ſometimes found fixed by the ſnout to the *eyes* of ſprats, whence it has received its name. It is about three inches in length, whereof the head is one quarter part. The body is ſomewhat thicker than a hog's briſtle, and of a pleaſant green colour. Phil. Tranſ. N° 472. § 7. or vol. xliii. p. 35.

EYE-*water*. See WATER.

EYE, *white of the*. See WHITE.

EYE-*glaſs*, in *Teleſcopes*, is the lens next the *eye*; and if the teleſcope conſiſt of more than two lenſes, all but that next the object are called *eye-glaſſes*.

EYE, *Bull's*, in *Aſtronomy*, a ſtar of the firſt magnitude, in the conſtellation Taurus, by the Arabs called *Aldebaran*. Its longitude, latitude, &c. ſee among thoſe of the other ſtars in the conſtellation TAURUS.

EYE, *cat's, Oculus cati*, in *Natural Hiſtory*, a precious ſtone, called alſo *ſun's eye, oculus ſolis*, and taken by Dr. Woodward for the aſteria of the ancients.

It is tranſparent, of a glittering grey, interchanged with a ſtraw-colour; uſually oblong as to figure, and not unlike the opal, only much harder. It is found in divers parts of the Eaſt Indies; but thoſe of the iſland of Ceylon are the moſt prized. See ASTERIA and CAT'S *eye*.

EYE, *crab's, Oculus cancrorum*. See CRAB'S *eyes*.

EYE, *goat's, Oculus caprinus*, is when there is a white ſpeck on the pupil of the *eye*, as is ſeen in the *eyes* of goats. Phyſicians call it *cataract*.

EYE, *golden, in Ornithology*. See DUCK.

EYE, *hare's, Oculus leporinus*, in *Medicine*, a diſeaſe ariſing from a contraction of the upper *eye-lid*, which prevents its being able to cover its part of the *eye*; ſo that the patient is obliged to ſleep with the *eye* half-open, after the manner of hares.

Phyſicians call it *lagophthalmia*, a Greek word, ſignifying the ſame thing, being compounded of λαγως, *hare*, and οφθαλμος, *eye*.

EYESS, in *Falconry*. See FALCON.

EYRE, or EIRE, in *Law*, ſignifies the court of juſtices itinerant.

The word ſeems formed of the old French *ire, itre, way or track*.

Hence juſtices in *eyre*, are thoſe whom Bracton calls *juſticiarii itinerantes*.

EYRE *of the foreſt*, is otherwiſe called *juſtice-ſeat*, which by the ancient cuſtoms was to be held every three years by the juſtices of the foreſt, journeying up and down for that purpoſe.

EYRIE, or AYRIE, among *Falconers*, the neſt where hawks ſit and hatch, and feed their young.

Hence, a young hawk newly taken from the neſt is called an *eyaſs*.

EZEKIEL, a canonical book of the Old Teſtament, referring chiefly to the degenerate manners and corruptions of the Jews in the times when the author wrote.

It abounds with fine ſentiments and rich compariſons, and diſcovers much learning in profane matters.

Ezekiel was carried captive to Babylon with Jechoniah or Jehoiachin, and began his prophecies in the fifth year of the captivity, or in the year before Chriſt 595. He was contemporary with Jeremiah, who propheſied at the ſame time in Judea. He foretold many events, particularly the deſtruction of the temple, the fatal cataſtrophe of thoſe who revolted from Babylon to Egypt, and the happy return of the Jews to their own land.

EZEKIEL's *reed*, or *rod*, a ſcripture meaſure, computed by late writers to amount to 1 Engliſh foot 11 inches $\frac{1}{2}$ of an inch.

EZQUADUITL, a name by which ſome authors have diſtinguiſhed the tree from which we have the common dragon's blood of the ſhops.

EZRA, or ESDRAS, in *Divinity*. *The Book of Ezra* is a book of Holy Scripture, compoſed in Hebrew by *Ezra* or *Esdras*, the high-prieſt of the Jews during the captivity; and particularly about the time when they returned to Paleſtine, under the reign of Cyrus.

This book contains the hiſtory of the Jews from the time of Cyrus's edict for their return, to the twentieth year of Artaxerxes Longimanus. It ſpecifies the number of Jews who returned, and Cyrus's proclamation for rebuilding the temple, the obſtruction it met with, and the finiſhing thereof in the reign of Darius. It is canonical, and allowed as ſuch both by the church and the ſynagogue.

The books of *Ezra*, called in the Engliſh verſion *the Firſt and Second Books of Eſdras*, though held by ſome, particularly the Greeks, for canonical, are thrown by the Engliſh church into the number of apocryphal books, being only extant in Greek.

The *Canon of Ezra* is the collection of the books of Scripture made by that prieſt. It appears, however, that the ſynagogue added other books to *Ezra's* canon; witneſs the book of *Ezra* itſelf, that of Nehemiah, and ſeveral others. See CANON.

F.

F, The ſixth letter of the alphabet, and the fourth conſonant.

The letter F may be either conſidered abſolutely, and in itſelf, or with regard to the particular languages where it is found. In the firſt view, *F* is generally placed by grammarians among the ſemi-vowels, and diſtinguiſhed in the enumeration of the alphabet by a name beginning with a vowel; though it has ſo far the nature of a mute that it is eaſily pronounced before a liquid in the ſame ſyllable. Joh. Conrad. Amman (in his Diſſertatio de Loquela) divides the conſonants into *ſingle* and double, and the *ſingle* into hiſſing and explosive. Among thoſe called hiſſing, there are ſome pronounced by the application of the upper teeth to the lower lip; and theſe are the *F* and *ph*. The reaſon why ſome account the *F* a ſemi-vowel, and Amman places it among the hiſſers, is, that one may pronounce a ſtile ſound without any other motion of the organs than what is neceſſary to the pronunciation of the *F*.

In Engliſh, its ſound is invariable, being formed by compreſſion of the whole lips, and a forcible breath.

This letter is derived to us from the Romans, who borrowed it from the Æolians; among whom it is called *digamma*, or *double gamma*, as reſembling two Γ's, one over the other: add, that the digamma ſeems in its origin to have been no other than the Greek Φ, which being made at three ſtrokes, degenerated at length into the figure *F*. For the letter Φ being compounded of an omicron with a perpendicular drawn through it, if that perpendicular be made firſt, and the O at two ſtrokes afterwards, viz. firſt the upper, then the under part, it may happen eſpecially in writing faſt, that the two parts ſhall not join; and even inſtead of two arches of circles, haſte and inconveniency may naturally enough make two ſtraight lines.

What confirms this tranſmutation of the Φ into *F*, is, that on the medals of Philip, and the kings of Syria, in the words ΕΠΙΦΑΝΟΥΣ and ΦΙΛΑΔΕΛΦΟΥ, the *ph* is frequently ſeen in the form juſt mentioned; i. e. it has no circle or omicron; but across the middle of the perpendicular is a kind of right line, formed only of two dots, the one on the right ſide, and the other on the left, repreſenting a croſs +. Such appears to be the origin of the letter *F*, which of conſequence is no other than a corruption of the Greek Φ; and accordingly, on the medals of the Faliſci the *F* is ordinarily put in lieu of the Greek Φ: but it muſt be added, that though the Greek and Latin letter were thus the ſame thing, yet the ſound was much ſofter among the Latins than among the Greeks, as was long ago obſerved by Terentianus.

The Romans for ſome time uſed an inverted F, Ⅎ, in lieu of a V conſonant, which had no peculiar figure in their alphabet: thus, in inſcriptions we meet with TERMINALIT. DIVI, &c. According to Lipſius, in his Comment on the Annals of Tacitus, lib. xi. Coverruvius and Douſquius, this inverted digamma Ⅎ was firſt introduced by the emperor Claudius. See Tacit. An. lib. xi. cap. 4. and Suet. in Vit. Claud. cap. 41.

It may be added, that the pronunciation of the *F* is almoſt the ſame with that of the V, as will be evident by attending to the manner of pronouncing the following words: *Favour, Vanity, Felicity, Vice, Foment, Vogue*, &c. The French, particularly, in borrowing words from other languages, uſually turn the final *v* into an *f*, as chef of caſtle, neuf of nouv, oef of navis, &c.

In the latter Roman writers we find the Latin *F* and Greek Φ, *ph*, frequently confounded; as in *Falanx* for *Phalanx*, *Filoſophia* for *Philoſophia*, &c. which abuſe is ſtill retained by many French writers, who write *Filoſophie, Filippe, Epiſane*, &c. and even ſometimes by the Engliſh, as in *fantaſy, filtre*, &c.

F, in the *Calendar*, is the ſixth dominical letter.

F, in the *Civil Law*. Two *ff*'s joined together ſignify the Pandects: ſee the reaſon of this under PANDECTS.

F, in our *Ancient Cuſtoms*, was a ſtigma or brand.

He that ſhall maliciouſly ſtrike any perſon with a weapon in church or church-yard, or draw any weapon there with an intent to ſtrike, ſhall have one of his ears cut off; and if he have no ears, he ſhall be marked on the cheek with a hot iron having the letter F, whereby he may be known for a fray-maker, or fighter.

F, or Fa, in *Muſic*, denotes the baſs-clef, being placed on the fourth line upwards.

Indeed the character or ſign by which the *f* and *c* clefs are marked bear no reſemblance to thoſe letters. Mr. Malcolm thinks it were as well if we uſed the letters themſelves; but cuſtom has eſtabliſhed otherwiſe. The ordinary character of the *f* or baſs clef is 𝄢, which Kepler takes a great deal of pains to deduce by corruption from the letter Γ inverted.

F, in the *Italian Muſic*, is often uſed inſtead of FORTE.

FF, in the *Italian Muſic*, ſtands for *forte forte*, and intimates to play very ſtrong and loud.

F, in *Phyſical Preſcriptions*, ſtands for *fiat, let it be done*, as *F. S. A.* denotes as much as *fiat ſecundum artem*.

F, among ſuch as give us the numeral value of letters, ſignifies 40, according to the verſe

Sexta quaterdenos gerit quæ diſtat ab alpha.

And when a daſh was added over it, F ſignified 40,000.

F, on the *French Coins*, is the mark of the town of Angers.

FA is one of the notes of muſic, being the fourth, riſing in the order of the gamut, *ut, re, mi, fa*. See NOTE.

FABA, in *Botany*. See BEAN.

FABA *Bengalenſis*, in the *Materia Medica*, a roundiſh compreſſed ſubſtance, about an inch in diameter, brought from Bengal, and thought to be a vitiated fruit of the myrobalans kind. It is a very good aſtringent, and therefore preſcribed with good ſucceſs in fluxes and hæmorrhages.

FABA *Græca*, in *Botany*. See *Indian Date* PLUM.

FABA *St. Ignatii*, in the *Materia Medica*. See NUX *vomica*.

FABA *purgatrix*, in the *Materia Medica*, the fruit of a ſpecies of *ricinus*. See PALMA *Chriſti* and CASTOR-*oil*.

FABACIUM, a word uſed by the ancients to expreſs a ſort of food then in uſe, which was a kind of cake made of bean-meal.

FABAGO, in *Botany*. See BEAN-*caper*.

FABALIS *Lapis*, in *Natural Hiſtory*, a ſtone mentioned by many ancient authors of repute as found in the river Nile, of the ſhape of a common bean, and of a black colour. They ſay it had the virtue of curing demoniacs, and that dogs durſt not bark if it was laid before them. Theſe, and many other like virtues, are attributed to this ſtone, to the great diſgrace of the ſober authors who relate them. The ſtone ſeems to have been of thoſe extraneous foſſils which Dr. Hill has ſtyled ICHTHYOPERIA, from their having been formerly parts of the bony palates of fiſhes which feed on the ſhell-fiſh kinds; and other authors SILIQUASTRI, from their reſembling the pod of the lupine or bean.

FABARIA, in *Botany*, a name given by ſome authors to the telephium or ORPINE, and by which it is in ſome places called in the ſhops.

FABARIA *calendæ*, among the Romans, the calends of June, ſo called becauſe the beans being then firſt ripe, ſome of them were offered to the goddeſs Carna, the wife of Janus.

FABATARIUM, among the ancients, ſignifies, according to ſome, a large veſſel in which beans were kept; others will have it to have been a kind of diſh or plate into which bean-puſſe was put and offered to the houſhold gods.

FABER, in *Ichthyography*. See DORER.

FABIANS, *Fabii*, in *Antiquity*, a part of the LUPERCI.

Thoſe prieſts conſiſted of two colleges, the firſt of which was called the *Fabii*, and the ſecond the Quinctilii, from their reſpective chiefs. The *Fabii* were for Romulus, and the Quintilii for Remus.

FABLE, a tale or feigned narration, deſigned either to inſtruct or divert; or, as Monſ. de la Motte defines it, an inſtruction diſguiſed under the allegory of an action.

Fable ſeems to be the moſt ancient way of teaching: the principal difference between the eloquence of the ancients and that of the moderns conſiſts, according to Pere Boſſu, in this; that our manner of ſpeaking is ſimple and proper, and theirs full of myſteries and allegories: with them the truth was uſually diſguiſed under thoſe ingenious inventions, called by way of excellence, *μυθοι*, *fabulæ*, *fables*; that is, words, as intimating that there was the ſame difference between theſe *fabulous* diſcourſes of the learned and the common language of the people, as between the words of men and the voices of beaſts.

At firſt *fables* were only employed in ſpeaking of the Divine Nature, as then conceived; whence the ancient theology was all *fable*. The Divine attributes were ſeparated as into ſo many perſons, and all the œconomy of the Godhead laid down in the feigned relations and actions thereof; either becauſe the human mind could not conceive ſo much power and action in a ſingle and indiviſible being; or, perhaps, becauſe they thought ſuch things too great and high for the knowledge of the vulgar; and as they could not well ſpeak of the operations of this Almighty Cauſe without ſpeaking likewiſe of its effects, natural philoſophy, and at length human nature, and morality itſelf, came thus to be veiled under the ſame *fabulous* allegoric expreſſion; and hence was the origin of poetry, and particularly of epic poetry.

The critics after Aphthonius and Theon reckon three kinds of *fables*, rational, moral, and mixed.

FABLES, *rational*, are called alſo parables: theſe are relations of things ſuppoſed to have been ſaid and done by men, and which might poſſibly have been ſaid and done, though in reality they were not. Such, in the ſacred writings, are thoſe of the ten virgins, of Dives and Lazarus, the prodigal ſon, &c. Of theſe rational *fables* we have likewiſe about a dozen in Phædrus.

FABLES, *moral*, called alſo apologues, are thoſe wherein not only beaſts, but trees, and other inanimate ſubſtances, are introduced as actors and ſpeakers. Theſe are alſo called *Æſopic fables*; not that Æſop was their inventor, for they were in uſe long before him, viz. in the times of Homer and Heſiod, but becauſe he excelled in them. Such was Jotham's *Fable* of the Trees, the moſt ancient of any that are now extant.

The *rational* differ from the *moral fable* in this; that the former, though it be feigned, might be true; but the latter is impoſſible, as it is impoſſible for brutes or ſtocks to ſpeak.

FABLES, *mixed*, are thoſe compoſed of both ſorts, rational and moral, or wherein men and brutes are introduced converſing together. Of theſe we have a fine inſtance in Juſtin. lib. xxxiii. cap. 4. made by a petty king to alarm the antient Gauls againſt the Maſſilians, who, arriving out of Aſia into Spain, charmed with the place, begged leave of the inhabitants to build a city. To this effect: A bitch big with young begged of a ſhepherd a place to lay her whelps in; which when ſhe had obtained, ſhe farther begged for leave to rear them there. At length the whelps being now grown up, depending on the ſtrength of her own family, ſhe claimed the property of the place. So the Maſſilians, who are now only ſtrangers, will hereafter pretend to be the maſters of this country.

As to the laws of *fable*, the principal are, 1ſt. That to every *fable* there be ſome interpretation annexed, to ſhew the moral ſenſe or deſign thereof. This interpretation, if it be placed after the *fable*, is called *επιμυθιον*, or *aſſumptio*; if before it, *προμυθιον*, *præfabulatio*. 2. That the narration be clear, probable, ſhort, and pleaſant. To preſerve this probability the manners muſt be expreſſed and cloſely kept to, as in poetry. See PROBABILITY and MANNERS.

M. de la Motte has ſome fine remarks on the ſubject of *fables*, at the beginning of his *Fables* Nouvelles, dediées au Roi, 1719. A *fable*, according to this polite writer, is a little epic poem, differing in nothing from the great one but in extent; and in that being leſs confined as to the choice of its perſons, it may take in all ſorts at pleaſure, as gods, men, beaſts, or genii; or even if occaſion be, create perſons; i. e. perſonify virtues, vices, rivers, trees, &c. Thus, M. de la Motte very happily introduces virtue, talent, and reputation, as perſons making a voyage together. See ETOPOEIA and PERSONIFYING.

That author ſuggeſts two reaſons why *fables* have pleaſed in all ages and places. The firſt is, that ſelf-love is ſpared in the inſtruction. The ſecond, that the mind is exerciſed by the allegory. Men do not love direct precepts; too proud to condeſcend to thoſe philoſophers who ſeem to command what they teach, they require to be inſtructed in a more humble manner; they would never amend, if they thought that to amend were to obey: add, that there is a ſort of activity in the mind which muſt be humoured; it pleaſes itſelf in a penetration which diſcovers more than is ſhewn; and in apprehending what is hid under a veil, fancies itſelf in ſome meaſure the author of it. The *fable* muſt always imply or convey ſome truth; in other works, delight alone may ſuffice; but the *fable* muſt inſtruct. Its eſſence is to be a ſymbol, and of conſequence to ſignify ſomewhat more than is expreſſed by the letter. This truth ſhould for the generality be a moral one; and a ſeries of fictions conceived and compoſed in this view would form a treatiſe of morality preferable to any more direct and methodical treatiſe; accordingly, Socrates, we are told, had a deſign to compoſe a courſe of morality in this way. This truth ſhould be concealed under the allegory; and in ſtrictneſs, it ought not to be explained either at the beginning or end.

The truth or idea intended ſhould ariſe in the reader's mind from the *fable* itſelf. However, for the convenience of the leſs diſcerning readers, it may be a good way to point out the truth or moral in preciſer terms. To have the moral at the end of the *fable* ſeems much better than at the beginning; the mind is apt to be foreſtalled in the latter caſe; I carry the key along with me, ſo that there is no room to exerciſe my mind in finding any thing myſelf.

The image, M. de la Motte obſerves, muſt be juſt, and expreſs the thing intended directly, and without any equivoque: it muſt be one; i. e. all the parts muſt be viſibly acceſſory to one principal end: and it muſt be natural; i. e. founded on nature, or at leaſt on opinion.

The writers of *fables* are not many. If there were any before Æſop, who lived in the time of Solon, about the fifty-ſecond Olympiad, his ſucceſs has quite effaced their memory; and even occaſioned all the good things of that kind to be aſcribed to him. His life, as written by Planudes, is itſelf a thorough *fable*. It muſt be owned to be very happily imagined to make the inventor of *fables* a ſlave, and his maſter a philoſopher: the ſlave has his maſter's pride and ill humour to deal with throughout. His leſſons were all contained in the *fables* themſelves, and the readers were left the pleaſure of diſcovering them.

It is generally allowed among the learned, that though the matter and invention of the *fables* be Æſop's, the turn and expreſſion are not. The Greek is of Planudes; and bad Greek it is, in the judgment of F. Vavaſſor, De Ludica Dict. Some authors will have Socrates the author of the *Fables* of Æſop; others attribute them to Solomon, and others to Homer.

Phædrus was a ſlave too, and a freed-man of Auguſtus; but he had the advantage over Æſop in education: he is only a *fabuliſt*, as he tranſlates and copies. Though his *fables* be generally ſhort, yet he is prolix compared with his author. His ſtyle, however, is always flowing, his deſcriptions conciſe, and his epithets ſuitable: he frequently adds graces never dreamt of by the inventor, and everywhere enriches the ſimplicity of Æſop in the moſt delicate manner.

Pilpay, another fabuliſt, governed Indoſtan a long time under a powerful emperor; but he was not the leſs a ſlave, for the prime miniſters of ſuch princes are always more ſo than the meaneſt ſubjects. Pilpay comprized all his politics in his *fables*; and accordingly his work long continued the book of ſtate, or the diſcipline of Indoſtan. It was tranſlated into Perſian and Arabic, and ſince into the modern languages. His *fables*, M. de la Motte obſerves, are rather famous than good: but he is the inventor, and the merit of invention will always compenſate for many faults. His *fables* are often wild and artleſs; and the collection is a ſort of romantic aſſemblage of men and genii, compoſed in its kind like Cyrus or Orlando, where the adventures are continually thwarting and claſhing with each other.

We ſay nothing of the *fables* of Gabrias, or Babrias. Avienus, who lived towards the end of the fourth century, under the empire of Gratian, Abſtemius, &c.

Among the moderns, the moſt celebrated writers are Meſſ. de la Fontaine and De la Motte: the firſt of whom has picked

but all the beſt things in *Æſop*, Phædrus, and Pilpay, and given them anew in French, with a delicacy and ſimplicity peculiar to himſelf; and which, in the judgment of his countrymen, ſets him even above Phædrus. The latter, rather than content himſelf with what De la Fontaine had left, choſe to be an inventor. He has ſucceeded. His *fables* are many of them very happy, though ſome think them too full of thought and reaſoning. His verſification is infinitely more correct than that of La Fontaine, and more ſuitable to the ſubject than that of Le Noble.

We have likewiſe ſome *fables* much eſteemed of Mr. Gay and Mr. Moore.

FABLE is alſo uſed for the plot of an epic or dramatic poem, or the action which makes the ſubject of ſuch a poem or romance. See POEM, DRAMA, EPIC, and ACTION.

The *fable*, according to Ariſtotle, is the principal part, and as it were the ſoul of a poem. It muſt be conſidered as the firſt foundation of the compoſition, or the principle which gives life and motion to all the parts. In this ſenſe the *fable* is defined, "A diſcourſe invented with art, to form the manners by inſtructions, diſguiſed under the allegory of an action."

The epic *fable*, according to Boſſu, is confined to the rational kind; i. e. the actors and perſons are to be gods and men; and yet it admits of great latitude: it may be either grave, illuſtrious, and important, or low and popular; either whole or defective, in verſe or in proſe; much epitomiſed, or brief; rehearſed by an author, or repreſented by actors on the ſtage; all which are ſo many circumſtances which do not make any alteration in the nature and eſſence of the *fable*.

The characters that ſpecify the epic *fable* are theſe: it is rational and probable; it imitates a whole and an important action; and it is long, and related in verſe: none of which properties affect the nature of the *fable*, or make it leſs a *fable* than thoſe of *Æſop*.

The *fable*, according to Ariſtotle, conſiſts of two eſſential parts, viz. truth, as its foundation; and fiction, which diſguiſes the truth, and gives it the form of *fable*. The truth is the point of morality intended to be inculcated; the fiction is the action, or words the inſtruction is covered under.

To make a plot or *fable*, the firſt thing, according to the great critic juſt mentioned, is to pitch on ſome moral inſtruction to be exemplified.

E. g. I would exhort two brothers, or other perſons, who have ſome common intereſt, to live in amity, in order to preſerve it. This is the end of the *fable*, and the firſt thing I have in view. In order to this, I endeavour to impreſs this maxim on our minds, that "ill "underſtanding ruins families, and all kinds of ſociety." This maxim is the moral or truth which is to be the ground of the *fable*; which moral truth is now to be reduced into action, and a general action to be framed from ſeveral ſingle and real actions of ſuch as were ruined by ill underſtanding.

Thus, e. g. I ſay, that certain perſons united together for the preſervation of ſomething that belonged to them in common, coming to diſagree, their diviſion left them open to an enemy who ruined them: ſuch is the firſt plan of a *fable*. The action preſented by this narration has four conditions; it is univerſal, imitated, feigned, and contains a moral truth under an allegory.

The names given to the ſeveral perſons begin to ſpecify the *fable*. *Æſop* uſes thoſe of brutes. Two dogs, ſays he, appointed to watch a flock, fall out, fight, and leave all open to the wolf, who carries off what he pleaſes.

If you would have the action more ſingular, and render the *fable* rational, take the names of men. Pridamant and Orontes, brothers by a ſecond venter, were left very rich by their father's will; but diſagreeing about the partition of their effects, they engaged themſelves ſo far againſt each other that they took no care of their common intereſt againſt Clitander, their eldeſt brother by the firſt venter, which laſt, artfully inflaming their quarrel, and ſeigning he had no view but to ſome moderate augmentation, which might be made him without oppreſſing them, in the mean time, gets the judges on his ſide, and the other perſons intruſted with the affair, procures the will to be aſſirmed, and becomes entitled to the whole eſtate about which the brothers were at variance. Now, this *fable* is rational; but the names being feigned as well as the things, and beſides, the perſons being only of a private rank, it is neither epic nor tragic. However, it may be employed in comedy, it being a rule laid down by Ariſtotle, that epic and tragic poets only invent things, but comic poets invent both names and things. See COMEDY, &c.

To accommodate this comic *fable* more to the mode and taſte of the town, ſome Donnda muſt be imagined to have been promiſed to Clitander; but her father, finding him diſinherited by the will, changes his reſolution, and will have her marry one of the rich, fenſeleſs, young brothers, whom ſhe deſpiſes, &c.

But to return. The fiction may be ſo diſguiſed with the truth of hiſtory that there ſhall not appear any *fiction* at all. To effect this the poet looks back into hiſtory for the names of ſome perſons to whom the feigned action either really, or probable did happen, and relates it under thoſe known names, with circumſtances which do not change any thing of the ground of the *fable*.

As for the *fable*, it matters but little whether the perſons be called dogs, or Orontes and Pridamant, or Robert of Anjou and Raſph de Neſle, or Achilles and Agamemnon.

The epic *fable* we ſhall now propoſe in its juſt extent under theſe two names laſt mentioned. It is too ſhort for the epopeia in the two preceding ones. We chooſe the *Fable* of the Iliad, as being the firſt plan of an epic poem in the world, and at the ſame time the moſt perfect ſyſtem of the precepts of the art, it being hence that Ariſtotle has formed it with all his reflections.

In every diſcreet undertaking the end is the firſt thing propoſed; and by this the whole work and all its parts are regulated; conſequently, the deſign of the epopeia being to form the manners, it is with this firſt view the poet muſt begin. Now, the philoſopher dwelling on virtues and vices in general, the inſtructions he gives ſerve equally for all ſtates and all ages; but the poet has a more immediate regard to his countrymen, and the preſſing occaſions of his fellow-citizens. On this ſcore it is that he chooſes his moral, which he is to inſinuate into the people by accommodating himſelf to their peculiar cuſtoms, genius, and inclinations. See HOMER.

Homer has acquitted himſelf in this part of his poſt. He ſaw the Greeks, in a manner, divided into as many ſtates as chiefs; and, in a manner, at war with one another, and had his governments to form in the midſt. Yet were theſe different ſtates engaged and united to unite into one body againſt the common enemy. Neither were two ſtates of government ſo different to be reconciliouſly lowered in one poem; the poet accordingly had recourſe to two *fables*; the one for all Greece, conſidered as confederated together, only conſiſting of independent parts; the other for each particular ſtate, ſuch as they are in time of peace, and without the firſt relation. The firſt is the ſubject of the ILIAD, the ſecond of the ODYSSEY.

For the firſt kind of government, all experience agrees that the only thing which can render it happy, and its deſign ſucceſsful, is a good underſtanding, and due ſubordination among the ſeveral chiefs that compoſe it; and that miſunderſtandings, a deſire of ſway, &c. are the inevitable bane of ſuch confederacies. The beſt inſtruction therefore that could be given them, was to let before their eyes the deſtruction of the people, and even of the princes themſelves, through the ambition and diſcord of theſe latter. Homer therefore, for the ground or moral of his *fable*, choſe this great truth, that the miſunderſtandings of princes ruin their ſtates. "I ſing, "ſays he, the wrath of Achilles, ſo fatal to the Greeks, "and which deſtroyed ſo many heroes, occaſioned by a "diſagreement between king Agamemnon and that "prince."

To enforce this truth, he repreſents divers confederate ſtates firſt at variance and unproſperous; then reconciled and victorious; all which he thus includes in one univerſal action. Several independent princes league againſt a common enemy; he whom they chooſe as their leader affronts the braveſt of all the confederates; upon which the offended prince withdraws, and refuſes any longer to fight for the common cauſe. This miſunderſtanding gives the enemy ſo much advantage that the confederates are ready to relinquiſh the enterpriſe. The diſaffected perſon himſelf becomes a ſharer in the calamities of his allies, one of his chief friends and favourites being killed by the chief of the enemies. Then both parties, grown wiſe by their own injury, are reconciled. Upon which the valiant prince, going again to the war, turns the ſcale to his own party, and kills the enemy's chief.

Such is the firſt general plan of the poem. To render this probable and more intereſting, circumſtances of time, place, perſons, &c. are to be added; that is, the poet looks into hiſtory or tradition for perſons to whom ſuch actions may with truth or probability be attributed.

He pitches on the ſiege of Troy, and ſuppoſes the action to have paſſed there. The brave, choleric character, he calls Achilles; the general, Agamemnon; the chief of the enemies, Hector, &c. To inſinuate himſelf into his readers, he accommodates himſelf to their manners, genius, views, &c. and to render his *fable* more intereſting,

resting, makes his chief persons, and those who remained victorious, to be Greeks, the fathers of those very people. The course of the work is filled up and extended with other useful lessons and instructions.

That the epopœia in all its glory is justly and strictly a mere *fable* in the same sense as the fictions of *Æsop* are, is shewn by F. Bossu, in a parallel between the *fable* of the Iliad and that of Æsop already mentioned. The moral instruction is visibly the same in both; so is the fiction. All the difference lies in the names and qualities of the persons.

Homer's are kings; he calls them Achilles, Patroclus, &c. and the general good to be preserved, he calls the Greeks. Æsop, after his manner, gives his persons the names of beasts: the dogs are confederated, the wolf is their enemy: and what Homer calls Greeks, Æsop calls sheep. One says, that while the confederate princes were at variance, Hector rushes on the Greeks, and makes them pay dear for the folly of their sovereigns (*dilaverat reges, pœnituitque Achivos*); but that the allies, brought by misfortunes to themselves again, re-unite, repulse Hector, and kill him. The other, that while the dogs are together by the ears the wolf falls on the sheep; and that the dogs, seeing the havock he makes, join together, drive him away, and kill him.

The two *fables* were capable of a still nearer resemblance. Homer has extended his by long speeches, descriptions, comparisons, and particular actions; that of Æsop might be amplified after the like manner, without corrupting or altering it. It is necessary only to relate what calls for the dogs at variance, and shew the rise of the fatal wrath: to all its circumstances; to make fine descriptions of the plain wherein the sheep fed, and of some neighbouring wood where the wolf was sheltered; to give this enemy whelps to rear, make them follow their sire in search of prey, and describe the carriage they made at divers expeditions. Nor should the genealogy of the heroes be forgotten; the wolf shall boast himself a descendant of Lycaon, and one of the dogs be sprung in a direct line from Canicula: which last would be the proper hero of the poem, as being hot, and apt to be enraged. He would represent the person of Achilles to admiration; and the folly of some Ajax, his cousin, would afford a good proof of so divine an extraction. Nothing more were required to engage heaven in the cause, and divide the gods; which, no doubt, have as much right in Æsop's republic as in the states of Homer. Witness Jupiter taking care to give a king to the nation of the frogs.

The reader has here field enough for an epopœia; if he have any thing of fancy and expreſſion, and do but take care to repeat as often as Homer does,

Τον δ' αυτ' ακουσας ωρορε ποδας ωκυς Αχιλλευς.

FABRIC, the ſtructure or conſtruction of any thing, particularly of a building.

The word is formed of the Latin, *fabrica*, which originally ſignifies a *ſmith's ſhop, or forge*.

In Italy the word *fabric* is applied to any conſiderable building; in France it rather ſignifies the manner of building.

FABRIC *lands*, are lands given towards the maintenance, rebuilding, or repair of cathedrals or other churches, mentioned in the Act of Oblivion, 12 Car. II. cap. 8.

In ancient time almoſt every one gave by his will more or leſs to the *fabric* of the cathedral or pariſh-church where he lived.

FABULOUS, denotes ſomething that has a relation to FABLE. Varro divides the duration of the world into two earlier ſtates or periods, called the *dark* and *fabulous*. See AGE.

FACE, the ſurface or firſt ſide which a body preſents to the eye. See SURFACE.

FACE is particularly uſed for the viſage of an animal, and eſpecially of a man, as being in him the only part of the body that ordinarily appears to the eye.

The Latins call it *facies, vultus, os*, &c.

The great variety obſervable in men's *faces*, voices, and hand-writings, furniſhes a noble argument of a Providence.

The human *face* is called the image of the ſoul, as being the ſeat of the principal organs of ſenſe; and the place where the ideas, motions, &c. of the ſoul are chiefly ſet to view. Pride and diſdain are ſhewn in the eye-brows, modeſty on the cheeks, majeſty on the forehead, &c. It is the *face* which ſhews the ſex, age, temperament, health, or diſeaſe, &c.

The *face*, conſidered as the index of the paſſions, habits, &c. of the perſon, makes the ſubject of phyſiognomy.

Anatomiſts uſually divide the *face* into two parts, the upper and lower: the upper is the front, or forehead; the lower includes the eyes, noſe, ears, mouth, cheeks, and chin. See each part deſcribed under its reſpective article.

FACE, or FACADE, *in Architecture*, is ſometimes uſed for the front of a building, or the ſide on which the chief entrance is; as alſo for the ſide it preſents to a ſtreet, garden, court, &c. and ſometimes for any ſide oppoſite to the eye.

FACE, FACIA, or FASCIA, alſo denotes a flat member having a conſiderable breadth, and but a ſmall projecture.

Such are the bands of an architrave, larmier, &c. See FASCIA.

FACE *of a gun*, in the *Artillery*, the ſurface of the metal at the extremity of the muzzle of a piece.

FACE, in *Aſtrology*, is uſed for the third part of a SIGN.

Each ſign is ſuppoſed to be diviſed into three *faces*: the ten firſt degrees compoſe the firſt *face*; the ten following ones the ſecond; and the laſt ten the third. Venus is in the third *face* of Taurus, that is, in the laſt ten degrees thereof.

FACE *of a plant*, in *Botany*, a word uſed by Tournefort and many botaniſts to convey an idea of that general appearance of plants, which ſhew a likeneſs in thoſe of the ſame *genus*, and a diverſity from other genuſes, though not eaſily characterized in words, yet very obvious to an eye accuſtomed to theſe reſearches. Thus, all the ſpecies of wormwood have the ſame *face*, by which they may be taken to be the ſpecies of the ſame *genus*, and ſo of many more; nay, in ſome caſes, whole *genera*, and even claſſes, have the ſame kind of *family-face*, as it may be called, by which they may be known; as the umbelliferous plants, except the *perfoliata*, and a few other inſtances.

It has been attempted by many to make this general *face* an indicatory note of the virtues of the plants which wears it; and there would certainly be this great advantage in it if it could be brought to any degree of certainty, that the moſt obvious of all diſtinctions would be applied to the moſt valuable office; but though an abſolute certainty cannot be arrived at in an attempt of this kind, yet allowing for the poſſibility of a few exceptions, general conjectures may be made on the following rules, which will rarely fail. The umbelliferous plants beforementioned make a very large claſs; and it is their general and obvious character to have their ſeveral flower-branches ariſe from one centre, and expand into an umbrella, every one having a tuft of flowers at the top: theſe flowers conſiſt of five leaves, and the ſeeds are naked and double, and the leaves of the plants are generally deeply diviſed, as in parſley, carrots, and the like.

This is a general *face* of a plant not eaſy to be miſtaken; and all the plants which have this *face* are endowed with the virtues of carminative medicines. They expel wind, and are good in the colic, and other the like diſeaſes. The ſeeds of moſt of theſe are uſed, and ſome of the roots. The ſeeds of aniſe, caraway, cummin, and the like, are all ſeeds of umbelliferous plants; and the root of *angelica* is another inſtance of their efficacy. But as an exception to this general rule, the hemlock, and hemlock-dropwort may be produced, which are poiſons.

The *verticillate plants* are another claſs, which are eaſily known by their general face; their flowers ſtanding in ringlets round the ſtalks, and being labiated, or of ſome ſuch form. The leaves alſo in moſt of theſe plants ſtand in pairs, and they have generally an aromatic ſmell. As the virtues of the *umbelliferæ* lie in the roots and ſeeds, ſo do theſe in the huſks of the flowers. It has been a common opinion, that the flowers of theſe plants contained their virtues, but this is erroneous. The flowers of ſage are almoſt inſipid, but the huſks taſte very ſtrongly. Theſe plants in general are poſſeſſed of the ſame virtues, and are all of a middle degree between the carminatives before mentioned and the ſpices. They are properly aromatics, and are all good in nervous diſeaſes, as epilepſies, palſies, and the like: one of them, which is called mother of thyme, is alone a remedy for the nightmare, a troubleſome diſeaſe, that often baffles other medicines; and the flowers of roſemary, lavender, ſage, and the like, may ſtand as inſtances of the virtues of this claſs; and mint, pennyroyal, hyſſop, &c. in their leaves are of great virtue, and a pleaſant flavour.

The *ſiliquoſe plants* have alſo a general *face*. Their flowers

flowers are compoſed of four leaves, and their ſeeds contained in long pods, or in ſhort and thick ſiliculæ. In theſe plants the ſeeds are found to contain the principal virtue in ſome, and in others the leaves; ſome have alſo virtue in their roots, but the flowers of all are neglected. Muſtard, creſſes, and the like, have their virtue in the ſeeds, and ſcurvy-graſs in its leaves, horſe-radiſh in the roots; yet all have the ſame general virtue; they are hot like the two laſt tribes, but they exert their power in a very different manner; as it conſiſts in a diuretic volatile ſalt; and they are all good in the ſcurvy, dropſy, jaundice, &c. and have been uſed in theſe caſes at all times. *Philoſ. Tranſ.* N° 255. p. 200. See BOTANY.

FACES *of a baſtion*, in *Fortification*, are the two foremoſt ſides reaching from the flanks to the point of the baſtion where they meet.

Theſe are commonly the firſt undermined, becauſe they reach fartheſt out, and are the leaſt flanked, and therefore weakeſt. They are repreſented by the lines B C and S C, *Tab. Fortif. fig.* 1.

FACE *of a place*, denotes the interval between the points of two neighbouring baſtions, containing the curtain, the two flanks, and the two *faces* of the baſtions that look towards one another.

This is otherwiſe called the TENAILLE of the place.

FACE *prolonged*, in *Fortification*, is that part of a line of defence raſant, which is between the angle of the epaule or ſhoulder of a baſtion and the curtain; or the line of a defence raſant diminiſhed by the *face* of the baſtion.

FACES, *external*, *Facies externa*, *in Ichthyology*, is uſed to expreſs a general form or figure in certain fiſhes, by means of which they agree with ſome and diſagree with others; and according to which likeneſs or diſſimilitude ſome authors of the late ages have arranged them into *genera*. This general figure in fiſhes conſiſts in the ſhape of the head and body, and the ſhape, ſize, and proportion of the fins and tail, and though very obvious, is very indiſtinct; it being in many caſes, where two fiſhes have the ſame general *external face*, yet hard to ſay, on a cloſe examination, in what it is that the likeneſs conſiſts. The authors who founded the diſtinction of the *genera* of fiſhes on theſe external reſemblances ran into very great *errors*; for it is not enough in a generical diſtinction for the character to be obvious, but it muſt alſo be preciſe and determinate. What this *faces* had in the firſt of theſe requiſites is often wanted in the laſt; and in general, it has been found to be no true baſis of diſtinction. Many fiſh have the *facies externa*, or general appearance ſo much alike, as to be eaſily coupled at ſight into the ſame genus; and that juſtly, as they really belong to the ſame when more preciſely referred to it, according to their natural and eſſential character. Of this kind are the gadi, the clupeæ, the ſalmons, the *petromyzæ*, the *exocœtæ*, the *pleuronectæ*, the rays, and many of the *cyprini*. In theſe the *facies externa* is of real uſe, as it is an obvious mark, and leads to the road of truth; but there are beſide theſe many other fiſhes, which, though they are truly of the ſame *genus*, yet differ extremely in their ſeveral external appearances, ſo that any method founded on the *facies externa* muſt ſeparate them, though nature had really joined them in their real characters.—The tench and the trutta lacuſtris, or lake-trout, are in regard to their *facies externa* extremely alike one to the other, yet here this obvious character deceives us; for the tench is a ſpecies of the cyprinus, and the other a true and genuine ſalmon, two *genera* of fiſhes eſſentially and very widely different, though this method of judging by the external appearance would have coupled together fiſh belonging to them both. In the ſame manner the *ſcorpæna* and *cottus* are very like one to the other in their external appearance; but when nicely examined, according to the rules of ichthyology, they are found to belong to two very different genera, and to have very little real likeneſs. From theſe, and numerous other examples of a like kind, it evidently appears, that as the *facies externa* cannot be depended on for eſtabliſhing the genera of fiſhes, ſome more eſſential characters muſt be enquired after for the regular and natural compoſition of this neceſſary buſineſs. Therefore, the generical characters of fiſh are to be ſought after in their external and invariable parts, and they are to be arranged into families and *genera*, according to the agreement of theſe in number, ſituation, figure, and proportion. Among all theſe, the characters taken from the number of the parts, where that is certain and invariable, are moſt valuable, as they moſt readily offer themſelves to the eye, and are leaſt of all liable to errors.

FACE, in the *Stocking*. See CHANFRIN.

FACE, in the *Military Language*, a word of command: thus, *face to the right*, is to turn upon the left heel a quarter round to the right; *face to the left*, is to turn upon the right heel a quarter round to the left.

FACE, among *Painters* and *Artiſts*, is uſed to denote a certain dimenſion of the human body, adopted for determining the proportion which the ſeveral parts ſhould bear to one another; for this purpoſe they commonly divide the height of the body into ten equal parts, called *faces*; becauſe the human *face* is the firſt model of theſe meaſures. Though the Apollo and Venus of Medici have more than ten *faces*. They again ſubdivide each of theſe *faces* into three equal parts; and this ſubdiviſion is founded on the conſideration, that the *face* is made to contain three equal parts; e. g. the firſt commencing above the forehead at the root of the hair, and ending at the root of the noſe, the noſe forming the ſecond part, and the third part ending juſt below the chin. See PROPORTION.

FACET, or FACETTE, a little face or ſide of a body, cut into a great number of angles.

Multiplying-glaſſes are cut in *facets*, or *facet-wiſe*. Diamonds are alſo cut in *facets* or tables.

In brilliants there are two ſorts, *ſtone*, or *ſkill-facets*, and *ſtar-facets*. *Skill-facets* are divided into upper and under. *Upper ſkill-facets* are wrought on the lower part of the beril, and terminate in the girdle.

Under ſkill-facets are wrought on the pavillions, and terminate in the girdle.

Star-facets are wrought on the upper part of the beril, and terminate in the table. Jeſſries on Diamonds. See DIAMONDS.

FACETANUS *Lacertus*, in *Zoology*, the name of a peculiar ſpecies of lizard, called at Rome and Naples the TARANTULA.

FACIA, in *Architecture*. See FASCIA.

FACIES *Hippocratica*, in *Medicine*, is when the noſtrils are ſharp, the eyes hollow, the temples low, the tips of the ears contracted and cold, the forehead dry and wrinkled, and the complexion pale or livid.

The *facies Hippocratica* is obſerved towards the period of phthiſies and other exhauſting diſeaſes, and is held a ſure prognoſtic of death, if it appears within three days after the attack of the diſeaſe. It is deemed to indicate death.

FACK, in a *Ship*. See FAKE.

FACTION, a cabal or party formed in a ſtate to diſturb the public repoſe.

The moſt celebrated *factions* are that of the Guelphs and Gibelins, who kept Italy in alarm for many ages; and with us that of the Whigs and Tories.

FACTION was originally an appellation given to the divers troops or companies of combatants in the games of the CIRCUS.

Of theſe there were four, viz. the *green faction*, the *blue faction*, the *red faction*, and the *white faction*. The emperor Domitian is ſaid to have added two others, viz. the *purple* and the *yellow*.

Theſe *factions*, with their liveries and badges, were at length aboliſhed; the emulation which was at firſt between them growing to ſuch a height, that in Juſtinian's time 40,000 men were killed in a conteſt between the *green* and *blue factions*.

FACTITIOUS, ſignifies any thing made by art, in oppoſition to what is the produce of nature.

De FACTO. ſee the article *De facto*.

FACTOR, in *Commerce*, an agent or perſon who acts and negociates for a merchant by commiſſion; called alſo commiſſioner, and on ſome occaſion broker, and throughout the Levant, coxgis.

Factors are either charged with the buying or the ſelling of goods, or with both.

Thoſe of the firſt kind are uſually eſtabliſhed in places of conſiderable manufactories, or cities of great trade. Their office is to buy up commodities for merchants reſiding elſewhere; to ſee them packed, and ſend them to the perſons for whom they were bought.

FACTORS *of ſale* are uſually fixed in places where there is a great vent. To theſe, merchants and manufacturers ſend their goods to be ſold for them according to the price and other conditions expreſſed in the orders delivered them.

The wages or allowances for ſelling are uſually clear of all expences of carriage, exchange, remittances, &c. excepting poſtage of letters, which are never put to account.

Factors ſhould ſtrictly obſerve the orders of their principals, or elſe they are liable to the damage accruing from the neglect of them. When *factors* have unlimited commiſſion to do for their conſtituents the beſt they can, they are excuſable, though their tranſactions are attended with loſs to their principals; but no *factor*, who has merely a commiſſion to ſell, &c. for another, is excuſable for entruſting another perſon beyond the uſual time allowed in the ſale of the commodities which he diſpoſes of: in ſuch a caſe he is anſwerable to the principal out of his own eſtate. If a *factor* ſells on the uſual truſt

trust to a person of good credit who afterwards becomes insolvent, he is discharged; but not if the man's credit was bad at the time of sale. A *factor* should always be punctual in the advices of his transactions, sales, purchases, freights, and draughts by exchange: he should never deviate from the orders he receives in the execution of a commission for purchasing goods, either with respect to price or quality: if goods that are bought are sent to a different place from that to which they were ordered, they become the *factor's* unless the merchant allows them. A *factor* that sells a commodity under the price ordered by his principal shall be obliged to make good the difference; and if he purchases goods for another at a limited price, and they rise in value, and he secures to himself the advantage, he is obliged to satisfy his principal for damages; or if he makes any advantage of the sale of goods which his principal directed him to purchase, the principals shall recover it from him, and he is liable to be amerced for the fraud. When *factors* have obtained a profit for their principal, they must be cautious how they dispose of it; for if they act without commission they are responsible; and if a merchant remits goods to his *factor*, and about a month after draws a bill on him, and the *factor* having effects in his hands, accepts the bill, but the principal breaks, and the goods are seized in the *factor's* hands on behalf of the creditors, it has been judged that the *factor* must answer the bill, and come in as a creditor for so much as he was obliged by reason of his acceptance to pay. If one employs a *factor*, and intrusts him with the dispofal of merchandife, and the *factor* receives the money, and dies, indebted to debts of higher nature, and it appears by evidence that this money was veſted in other goods, and remains unpaid, thoſe goods ſhall be taken as part of the merchant's, and not of the *factor's* eſtate; but if the *factor* has the money, it ſhall be conſidered as the *factor's* eſtate, and muſt firſt anſwer the debts of ſuperior creditors, &c. If a perſon employs a *factor* to ſell goods, who ſells them on credit, and before the money is paid dies indebted more than his eſtate will pay, this money ſhall be paid to the principal merchant, and not to the *factor's* adminiſtrator, deducting his commiſſion. A *factor* who has money in hand belonging to his principals, and who neglects to inſure a ſhip and goods according to order, ſhall make good the damage if the ſhip miſcarry; and if he make any compoſition with the inſurers after inſurance without orders, he is anſwerable for the whole inſurance. As fidelity and diligence are required from the *factor*, ſo the law requires the like from the principal: if, therefore, a merchant remits counterfeit jewels to his *factor*, who ſells them as true ones, and ſuffains loſs or damage by impriſonment or other puniſhment, the principal ſhall not make ſatisfaction to the *factor* but to the party who purchaſed them. Buſineſs of this kind is called commiſſion-buſineſs; and traders in this way have current as well as commiſſion accounts conſtantly between them, and draw on, remit to, and ſend commiſſions to each other only by the intercourſe of letters, which, among men of honour, are as obligatory and authoritative as all the bonds and ties of law.

FACTORS, in *Arithmetic*, is a name given to the two numbers which are multiplied one into another; that is, the multiplicand and multiplier; ſo called becauſe they are to *facere productum*, make or conſtitute the product.

FACTORAGE. The *factorage* or wages, called alſo commiſſion, is different at different places, and for different voyages: at a medium it may be fixed at about three *per cent.* of the value of the goods bought, beſide the charge of package, which is paid over and above.

At Virginia, Barbadoes, and Jamaica, the *factorage* is about eight *per cent.* and the like throughout the greateſt part of the Weſt Indies. In Italy it is two and a half; in Holland one and a half: in Spain, Portugal, France, &c. it is two *per cent.*

FACTORY, a place where a conſiderable number of factors reſide, to negociate and officiate for their maſters or principals.

The term is chiefly uſed in ſpeaking of the Eaſt Indies, and other parts of *Aſia*. Turkey, Italy, Portugal, &c. whither the European nations ſend their ſhips every year, and where they keep factors to buy the commodities of the country, and ſell thoſe brought from Europe.

FACTUM, in *Arithmetic*, the product of two quantities multiplied by each other.

FACULÆ, in *Aſtronomy*, a name given by Scheiner, and others after him, to certain ſpots on the ſun's diſk that appear brighter and more lucid than the reſt of the body.

The word is pure Latin, being a diminutive of *fax, torch*, and ſuppoſed to be here applied from their appearing and diſappearing by turns.

The *faculæ* or bright ſpots differ very conſiderably from the maculæ or dark ſpots; both in light, colour, figure, magnitude, and duration.

Heſelius aſſures us, that July the 20th, 1634, he obſerved a *facula* that took up a third part of the ſun's diameter; and from the obſervations of the ſame Heſelius we learn, that the maculæ frequently change into *faculæ*; but the *faculæ* into maculæ rarely, if ever. Some authors even contend that all the maculæ degenerate into *faculæ* before they quite diſappear.

Huygens, however, declares he was never able to diſcover any *faculæ*, though the *maculæ* occurred to him very frequently. All the foundation he could find for the notion of *faculæ*, he ſays, was, that in the darkiſh clouds which frequently ſurround the maculæ, one ſometimes diſcerns little points or ſparks brighter than the reſt.

Many authors after Kircher and Scheiner have generally repreſented the ſun's body full of bright, fiery ſpots, which they conceive to be a ſort of volcanos in the body of the ſun; but Huygens, and others of the beſt and beſt obſervers, finding, that the beſt teleſcopes diſcover nothing of the matter, agree to explode the phenomena of *faculæ*. Their cauſe theſe authors attribute to the tremulous agitation of the vapours near our earth; the ſame as ſometimes ſhews a little unevenneſs in the circumference of the ſun's diſk when viewed through a teleſcope. Strictly, then, the *faculæ* are not eructations of fire and flame, but refractions of the ſun's rays in the rarer exhalations, which, being condenſed in the neighbourhood of that ſhade, ſeem to exhibit a light greater than that of the SUN. See SPOTS.

FACULTY, a power or ability of performing an action.

The term is much uſed by the ancient philoſophers, and ſtill remained in the ſchools for explaining the actions of natural bodies.

Thus, to account for the act of digeſtion, they ſuppoſe a digeſtive *faculty* in the ſtomach; to account for motion, they imagine a motive *faculty* in the nerves, &c. which is only a ſubſtituting of one name of an unknown phenomenon for another.

Yet this practice of attributing effects to their reſpective virtues or *faculties* ſtill obtains in divers things, which our philoſophy has not yet afforded us a better account of. Thus, ſay our medicinal writers, ſenna and rhubarb have a purgative *faculty*, barberries a cooling *faculty*, &c. which amounts juſt to this, that ſenna purges, and barberries cool.

The FACULTIES *or powers of the ſoul* are commonly reputed two, viz. the underſtanding and will.

The FACULTIES *of the body* are uſually diſtinguiſhed with regard to their ſeveral functions, into *vegetative* and *animal*.

Under the *vegetative faculty* are comprehended the divers ſubaltern ones, whereby nutrition and generation are effected.

Under the *animal faculties* are comprehended thoſe relating to ſenſe and motion.

The *vegetative faculty* is ſubdivided into *nutritive* and *generative*, and the nutritive is again ſubdivided into *naturæ* and *vitæ*.

To the firſt belong the functions of the lower belly, relating to the preparation of the food; to the latter, the actions of the heart and lungs, wherein life is chiefly concerned.

Others ſubdivide the *vegetative faculty* into *attractive, retentive, concoctive*, and *expulſive*.

The *animal faculties* being thoſe whereby an animal perceives and moves, become divided into *ſenſitive* and *locomotive*.

FACULTY is alſo applied in the *Schools*, to the divers parts or members of an univerſity, divided according to the arts or ſciences taught or profeſſed there.

There are four *faculties* in moſt univerſities; that of arts, which includes the humanities and philoſophy, and is much the moſt ancient and extenſive; the ſecond is that of theology; the third, medicine; and the fourth, juriſprudence, or laws. See each under its proper article.

The degrees in the ſeveral *faculties* in the univerſities are thoſe of Bachelor, Maſter, and Doctor.

The FACULTY is frequently uſed abſolutely, and by way eminence, for that chiefly ſtudied and taught in that place.

Thus, the *Faculty* of London and Montpelier is medicine; that of Paris, theology; that of Orleans, law, &c.

FACULTY, in *Law*, denotes a privilege or ſpecial power granted to a man by favour, indulgence, and diſpenſation, to do that which regularly by law he cannot; as to eat fleſh upon days prohibited, or to marry without banns firſt aſked, &c.

FACULTIES, *the Court of*. See COURT *of Faculties*.

FACULTY *of Advocates*, in Scotland. See ADVOCATE.

FÆCES, or FECES, denotes the dregs, ſediment, or impurities,

remaining of a mixt body, after the purer, more volatile, and fluid, have been separated from it by evaporation, diſtillation, decantation, derivation, or the like.

Thus we ſay the *faces* of wine, of oil, &c. Thoſe of wines are properly called *lees*; thoſe of oil, *ſaburra*; thoſe of malt liquors, *grounds*.

FACES, in *Chymiſtry* denotes, the lees, refuſe, dirt, mud, impurities, and other groſſer matters, remaining in the alembic after the diſtillation of any body: what remains in the retort, inſtead of *faces*, is properly denominated *caput mortuum*, or *terra damnata*.

FACES is particularly uſed in *Medicine*, &c. for the groſs, impure matters found at the bottom of the compoſitions and preparations of either pharmacy.

FACES is alſo uſed for the EXCREMENTS of an animal voided by ſtool.

The *fæcal* matter is become famous for a chemical operation thereon, by M. Homberg, related at length in the Mem. de l'Acad. R. an. 1711. He had a notion ſuggeſted to him, that the *human faces* by diſtillation yielded an oil clear as water, without any ſmell, and which had the property of fixing mercury into fine ſilver. Upon this, becauſe he would have no ſcruples about procuring a matter as he could, he hired four robuſt healthy young fellows, whom he ſhut up for three months, and agreed with them, that they ſhould eat nothing but the ſtaleſt bread, with which he ſupplied them freſh every day, and drink the beſt Champaign wine as long as they could. After a long proceſs, and numerous eſſays on the excrements they made, he at length got the clear, inodorous oil; but it had no effect at all on mercury, which was the great point aimed at. As the method of working on this diſagreeable matter, however, at length furniſhed him with a very fine phoſphorus, it may be worth the attention of the curious.

FÆCULA. See FECULA.

FÆSTING *Man*. See FASTERMANS.

FÆTOR. See FOETOR.

FÆX *Vitri*, in *Chymiſtry*, a name given by Rulandus and ſome other of the writers, to the common nitre of ſaltpetre, and by others to pot-aſh.

FA FINTO, a *feigned* F, in the *Italian Muſic*, is what we commonly call the FLAT of any note.

FAG, is uſed for a knot or excreſcency in cloth. Stat. 4 Ed. IV. cap. 1.

FAG *end*, in the *Sea-language*, denotes the end of any rope or cord which is become untwiſted and looſened by frequent uſe; to prevent which, the ends of ropes are generally well ſeſtened by winding a piece of ſmall line or pack-thread around them, which operation is called whipping.

FAGARA, in *Botany*, a genus of the *tetrandria monogynia* claſs. The calyx is cut into four ſegments; the corolla has four petals; and the capſule is bivalve, and contains a ſingle ſeed. There are four ſpecies.

FAGARA, in the *Materia Medica*, the name of a fruit reſembling the cubebs found in the Philippine iſlands. The part of this fruit which contains the principal virtue is the outer rind; this is tender and blackiſh, and of an aromatic and ſomewhat acid taſte. When the berries are ripe they eaſily break, and diſcloſe a black, ſhining, ſolid kernel, void of taſte and ſmell. The berries, according to Avicenna, are heating and drying, and good for a cold weak ſtomach, to help digeſtion, and are aſtringent to the bowels. They were once much uſed, but of late are ſcarce known in the ſhops.

FAGGOT, in *Agriculture*. There is a thing worth obſerving to the owners of the woods in the article of the making up the underwood into *faggots*. The workmen, when they have bound up the *faggot*, trim off the ſuperfluous branches from the ſides and end to make it more neat, and theſe they add to the middle of the next; but they are of little or no advantage there, and ought to be left on the ground; for being ſmall, they would ſoon rot there, and would manure the ground ſo as to be of more advantage to the next growth than is eaſily imagined. The leaves of the trees falling to the earth, manure it very much; but this is nothing to the advantage of thoſe little pieces of wood: any rotten wood, but in a moderate quantity, will turn a common bad earth into good garden mould; and the growth of the young trees is more forwarded by this manure where it is left than by any other means that can be uſed to it. We always ſee the land where wood-ſtacks have ſtood enriched to a ſurpriſing degree by them; and the ſame advantage will be wherever wood of any kind is left to moulder and rot upon the ground.

FAGGOT, or FAGOT, in *Fortification*. See FASCINE.

FAGGOTS *for fuel* are required by 43 Eliz. cap. 14. to contain in compaſs, beſides the knot of the bond, twenty-four inches of aſſize; and every *faggot-ſtick* within the bond ſhall contain full three feet of aſſize, except only one ſtick, which is to be but one foot long, to help to harden the binding.

FAGGOT *of ſteel*, expreſſes the quantity of 120 lb. weight.

FAGGOT, in the times of Popery in theſe kingdoms, was a badge worn on the ſleeve of the upper garment by ſuch as had abjured herely, being put on after the perſon had carried a *faggot*, by way of penance, to ſome appointed place of ſolemnity. The leaving off this badge was ſometimes interpreted a ſign of apoſtaſy.

FAGGOTS, among the *Military Men*, are ineffective perſons who receive no regular pay, nor do any regular duty, but are hired occaſionally to appear at a muſter, to fill up the companies, hide the real deficiencies thereof, and cheat the king of ſo much pay, which goes into the officer's pocket.

FAGONA, in *Botany*, a conglomerate gland, called alſo THYMUS.

FAGONIA, in *Botany*, a genus of the *decandria monogynia* claſs. Its characters are theſe: the flower hath five heart-ſhaped petals which ſpread open, and are narrow at their baſe where they are inſerted in the cup; and hath ten erect ſtamina. In the centre is ſituated a five-cornered germen, which afterwards becomes a roundiſh capſule, having five lobes ending in a point, and five cells, each having a ſingle roundiſh ſeed. There are three ſpecies. Miller's Gard. Dict.

FAGOPYRUM. See *Buck* WHEAT.

FAGOTTINO, in the *Italian Muſic*, the name uſed for the ſingle curtail, which is a muſical inſtrument ſomewhat like the baſſoon.

FAGOTTO, in the *Italian Muſic*, the name of the double curtail, being as big again as the fagottino, and in reality the ſame with a BASSOON.

FAGUS, in *Botany*. See BEECH-*tree*.

FAGUTAL, in *Mythology*, a temple of Jupiter, ſo called from *fagus*, the *beech*, a tree ſacred to Jupiter; becauſe, as ſome ſay, the temple was [illegible] neighbourhood of a foreſt of *beeches*; [illegible] that they ſay that part of mount Eſqu[illegible] only called *Mons Oppius* was afterwa[illegible] and that Jupiter *Fagutalis* was the ſame [illegible] ſubdued.

FAHNELEN, FAHNLEHEN, among the Germans, a kind of greater fiefs which the emperor alone could confer.

This was done by the delivery of a ſtandard, whence they had the name of *fahnelen*; i. e. *feoda vexilli*. We find them mentioned in the golden bull of the emperor Charles IV. ann. 1356: *Feudis principum exceptis, & illis quæ vaniehen vulgariter appellantur, quorum inveſtituram & collationem ſolo imperatori, vel regi Romanis ſpecialiter reſervamus*. Du-Cange Gloſſ. Lat. in voc.

The word is more uſually written *fahnlehen*.

FAIDA, in our *Old Writers*, is uſed for malice or deadly feud. Leg. Hen. I. cap. 83.

FAILLS, in *Heraldry*, a French term, denoting ſome failure or flaw in an ordinary, as if it were broke, and a ſplinter taken from it.

FAILURE, or FAILING, a ſpecies of BANKRUPTCY, popularly called breaking or ſtopping payment.

FAILURE *of record*, in *Law*, is uſed when an action is brought againſt a man who alledges in his plea matter of record in bar of the action, and endeavours to prove it by the record. The plaintiff replies, *nul tiel record*; that is, he denies there is any ſuch record. Upon which the defendant has a day given him by the court to bring it in; and if he fails to do ſo, he is ſaid to fail of his record, and the plaintiff ſhall have judgment to recover.

FAINT, or FAINT-ACTION, in *Law*, is as much as *feigned action*; that is, ſuch an ACTION as, though the words of the writ be true, yet, for certain cauſes, the party has no title to recover thereby.

By which it differs from falſe action, which is that where the words of the writ are falſe.

Yet ſometimes the two are confounded.

FAINT *pleader*, in *Law*, a fraudulent, falſe, or colluſive manner of pleading, to the deceit of a third perſon. Againſt which, among other things, was made the ſtatute 3 Edw. I. cap. 29.

FAINTS, in the *Diſtillery*, the weak ſpirituous liquor that runs from the ſtill in rectifying the low wines after the proof-ſpirit is run off.

FAINTS is alſo the laſt runnings of all ſpirits diſtilled by the alembic. The clearing of the worm of theſe is ſo eſſential a point in order to the obtaining of a pure ſpirit by the ſucceeding diſtillation, that all others are fruitleſs without it.

FAINTING. See LIPOTHYMIA and SWOONING.

Some people are extremely apt to *faint* during the operation of bleeding. In all caſes, therefore, where plentiful bleeding is indicated, it is beſt to do it in bed, in order to prevent the patient's *fainting*. It is likewiſe obſerved,

observed, that a person will bear the loss of a much greater quantity of blood, if the stream is small, than by a large orifice, which some think necessary for making a more speedy revulsion. Pringle, Observ. on the Diseases of the Army, p. 317.

FAIR, a public place, where merchants, traders, and other persons from divers parts, meet, on some stated day in the year, to buy and sell commodities, and to partake of the diversions usually accompanying such assemblies: or it denotes the concourse of people assembled on such occasions. See MARKET.

The word *fair* is formed of the French *foire*, which signifies the same thing; and *foire*, some derive from the Latin *forum, market*; others from the Latin *feriæ*, because *fairs* were anciently always held in the places where the wakes, or feasts, of the dedication of churches, called *feriæ*, were also held. The Romans called them *nundinæ*. Eric Puteanus has a pretty little treatise on the *fairs* of the Romans, De Nundinis Romanorum, which he calls *sacer fasciculus florum*.

Fairs can only be established by virtue of the king's grant, or by long and immemorial usage and prescription, which supposes such a grant; he is also the sole judge where *fairs* and markets ought to be kept; and if any person set up a *fair*, without the king's authority, a *quo warranto* lies against him; and the persons who frequent such *fairs*, &c. may be punished by fine to the king. Every *fair* is subject to the regulation of the COURT of *pie-powder*. The duration of *fairs* is determined by proclamation; and if a person shall sell any goods after the time of the *fair* expires, he shall incur a forfeiture of double the value of the goods sold, one fourth to the prosecuter, and the rest to the king. 5 Ed. III. cap. 5. Any citizen of London may carry his goods to any *fair* or market in England at his pleasure. If any person is intitled to hold a *fair* or market, and another is set up within the distance of a third part of twenty miles, either on the same day, or a different day, it is a nuisance, and an action on the case lies: and also against persons disturbing such as are coming to buy or sell at the *fair* or market, so that the person holding the *fair*, &c. loses his TOLL, or receives prejudice in the profits arising from it.

Fairs abroad are either free, or charged with tolls and impositions. The privileges of free *fairs* consist chiefly, 1. In that all traders, &c. whether natives or foreigners, are allowed to enter the place, and are under the royal safeguard and protection in coming and returning, they and their agents, with their goods, &c. 2. In that the said persons, and their effects, are exempt from all duties, impositions, tolls, and servitudes. 3. That merchants, in going to, or returning from the *fair*, &c. cannot be arrested, or their goods stopped, &c. It is the sovereign alone that has a right, by his letters patent, to establish *fairs*, whether free, or subject to duties, and the other ordinary laws and penalties.

Several fairs are held in the open fields, or on heaths and commons, under tents, booths, and barracks, erected for the purpose; as Stourbridge *fair*, &c. others in places walled in for the purpose, and formed into regular streets, lanes, &c. for the occasion: as the *fair* of St. Laurence at Paris. Lastly, others are held in the open places and streets of cities; as Bristol *fair*, the *fair* of St. Germains, &c.

Fairs, particularly free *fairs*, make a very considerable article in the commerce of Europe, especially that of the Mediterranean or inland parts; as Germany, &c. when the continual passage and repassage of vessels are impracticable.

The most celebrated *fairs* in Europe are those, 1. of Francfort, held twice a year, in spring and autumn; the first commencing the Sunday before Palm-Sunday, and the other in September. Each is declared by sound of bell, and lasts three weeks; the first of which is called the week of acceptance, and the second the week of payment; though many bills of exchange are now payable in the third week, but this must be mentioned, because every bill payable in the *fair* is, without such a clause, deemed payable in the second week. They are famous for the sale of all kinds of commodities, but particularly an immense quantity of curious books, no where else to be found; and from whence the booksellers, throughout all Europe, used to furnish themselves. Before each *fair*, there is a catalogue of all the books to be sold at it, printed and dispersed, to call together purchasers; though the learned have generally complained of divers unfair practices therein; as fictitious titles, names of books purely imaginary, &c. beside great faults in the names of the authors, and the titles of the real books. 2. The *fairs* of Leipsic, which are held thrice a year; one beginning on the first of January, another three weeks after Easter, and a third after Michaelmas; they last twelve days each, and are, at least, as considerable as those of Francfort. 3. The *fairs* of Novi, a little city in the Milanese, under the dominion of the republic of Genoa. There are four of these in the year; commencing on the first of February, the second of May, the first of August, and second of November. Though the commodities bought and sold here be very considerable, yet what chiefly contributes to render them so famous, is the vast concourse of the most considerable merchants and negociants of the neighbouring kingdoms, for transacting affairs, and settling accounts in matters of bank and exchange. Each of these usually lasts eight days. 4. The *fairs* of Riga, whereof there are two in the year; one in May, and the other in September. They are much frequented by the English, Dutch, and French ships; as also by others from all parts of the Baltic. The best time for the sale of goods at Riga, is during the *fairs*. Since the building of the famous city of Petersburg, these *fairs* have suffered some diminution. 5. The *fair* of Archangel; during which, all the trade foreigners have with that city is managed. It continues a month, or six weeks, at most; commencing from the middle of August. The Muscovite merchants attend here, from all parts of that vast empire; and the English, Dutch, French, Swedish, Danish, and other ships in the port of that city, on this occasion, ordinarily amount to three hundred. But this is no free *fair*, as the rest are: the duties of exportation and importation are very strictly paid, and on a very high footing. 6. The *fair* of St. Germain, one of the suburbs of Paris, commencing on the third of February, and holding till Easter; though it is only free for the first fifteen days. It is frequented by traders with various sorts of cloths and stuffs; and the goldsmiths, jewellers, and toy-men of Paris, have well furnished and handsome shops in it. 7. The *fairs* of Lyons, which Mons. Du Chesne, in his Antiquity of Cities, would insinuate from a passage in Strabo, were established by the Romans, though this certain, the *fairs*, as they now stand, are of a much later date. There are four in the year, each lasting twenty days, and free for ever. They begin on the first Monday after Low Sunday, the fourth of August, the third of November, and the first Monday after Easter. 8. *Fair* of Guibray, a suburb of the city of Falaise, in the Lower Normandy. It is said to have been established by our William the Conqueror, in consideration of his being born at Falaise. It commences on the fifteenth of August, and lasts fifteen days; free by charter, and longer by custom. 9. *Fair* of Beaucaire, held partly in a city of that name, in Languedoc, and partly in the open country, under tents, &c. It commences on the twenty-second of July, and only continues for three days; yet it is the greatest, and most celebrated, of all the *fairs* in that part of Europe, both for the concourse of [illegible] from all parts of the world, and for the traffic of all kinds of goods: the money returned, in these three days, amounting sometimes to above six millions of livres. Besides these, there are 10. France several other *fairs* of considerable note; as the four fairs of Rheims, the two of Rouen, two of Bourdeaux, two of Troyes, two of St. Dennis, that of Caen, of Dieppe, and of Toulon, &c.

The *fairs* of Porto-Bello, Vera-Cruz, and the Havannah, are the most considerable of all those in the Spanish West Indies. The two first last as long as the flota and galleons continue in those parts; and the last is opened as soon as the flota, or galleons, arrive there, upon their return for Spain; thus being the place where the two fleets join.

The principal *fairs* in Great Britain are, Stourbridge-*fair*, near Cambridge; the two *fairs* of Bristol, that of Exeter, West Chester, Edinburgh, Weyhill, and Burford *fairs*, for sheep; Panerals *fair*, in Staffordshire, for saddle-horses; Barnet *fair*, near London, for lean and Welsh black cattle; St. Faith's, in Norfolk, for Scots runts; Yarmouth fishing *fair* for herrings; Ipswich butter *fair*; that of Woodborough Hill, near Blandford in Dorsetshire, famous for west-country manufacture, Devonshire kerseys, Wiltshire druggets, &c. two cheese-*fairs* at Atherston and Chipping Norton; besides many more *fairs* and weekly markets in different parts of the kingdom.

FAIR, in *Sea Language*, is used for the disposition of the wind, when it is favourable to a ship's course, in opposition to that which is contrary and foul. The term *fair* is more comprehensive than large, and includes about fifteen or eighteen points of the compass; whereas large is confined to the beam or quarter, that is, to a wind which crosses the keel at right angles, or obliquely from the stern, but never to one right astern. Falconer's Marine Dict.

FAIR *curve* is a winding line, used in delineating ships, whose shape is varied, according to the part of the ship which it is intended to describe.

FAIR-*pleading*, in *Law*. See BEAU-*pleader*.

FAIR-way, in *Sea Language*, the path or channel of a narrow bay, river, or haven, in which ships usually advance in their paſſage up and down; ſo that if any veſſels are anchored therein, they are ſaid to lie in the *fair-way*. Falconer.

FAIRY, a term frequently occuring in ancient traditions and romances, denoting a kind of genii, or imaginary deities, conſtant on earth, and diſtinguiſhed by abundance of fantaſtical actions and offices, either good, or evil.

The *fairies*, according to theſe traditions, are a peculiar ſpecies of divinities, that have but little relation to any of thoſe of the ancient Greeks and Romans; unleſs, perhaps, to the latter; though others will not have them ranked among deities, but ſuppoſe them an intermediate kind of beings, neither gods, nor angels, nor men, nor devils.

They are of oriental extraction, and ſeem to have been invented by the Perſians and Arabs, whoſe hiſtory and religion abound with tales of *fairies* and dragons. The Perſians call them Peri, and the Arabs Ginn; having a peculiar country, which they ſuppoſe them to inhabit, called Giunniſtan; and, by us, *Fairy Land*. Our famous countryman Spenſer's maſter-work, the *Fairy Queen*, is an epic poem under the perſons and characters of *fairies*.

FAIRY *circle*, or *ring*, is a phenomenon pretty frequent in the fields, &c. being a kind of round, ſuppoſed, by the vulgar, to be traced by the *fairies* in their dances.

There are two kinds: one of them ſeven or eight yards in diameter, containing a round bare path, a foot broad, with green graſs in the middle; the others of divers ſizes, being encompaſſed with a circumference of graſs, much ſreſher and greener than in the middle.

Mr. Jeſſop, and Mr. Walker, in the Philoſophical Tranſactions, aſcribe them to the lightning; which is confirmed, by their being moſt frequently produced after ſtorms of that kind; as well as by the colour and briſkneſs of the graſs-roots, when firſt obſerved. It is no wonder that lightning, like all other fires, moves round, and burns more in the extremity than in the middle.

According to theſe gentlemen, the ſecond kind of circle ariſes originally from the firſt; the graſs burnt up by the lightning uſing to grow the more plentifully afterwards. Phil. Tranſ. abr. vol. ii. p. 182.

It is not improbable that theſe *fairy* rings may be of the ſame kind with thoſe CIRCULAR *ſpots* produced on the ſurface of metal by large electrical exploſions. The chief objection againſt this hypotheſis is, that in theſe rings there is no appearance of any thing correſponding to the central ſpot in ſuch electrical impreſſions; and that they have no regular concentric circles, nor an invariable circular figure. Mr. Walker, however, found one of theſe rings immediately after a thunder ſtorm, which he could alſo be no other cauſe but the lightning. Ubi ſupra. Other authors have aſſerted, that theſe *fairy-rings* are formed by ants: becauſe thoſe inſects are ſometimes found travelling in troops therein; and others, that they are beds of muſh-worms.

FAIT, *Fadium*, in *Law*, is uſed for a writing lawfully executed to bind the parties thereto. See DEED.

FAITH, *Fides*, in *Antiquity*, as denoting honeſty or fidelity, was deified by the Romans, and repreſented with an even open air, and dreſſed in a thin robe, ſo fine, that one might ſee through it. This deity is alſo repreſented as very old and grey-headed; and ſhe appears on medals as giving her hand, and ſometimes only by two hands joined together.

FAITH, in *Philoſophy* and *Theology*, that aſſent which we give to a propoſition advanced by another, the truth of which we do not immediately perceive from our own reaſon or experience; or it is a judgment, or aſſent of the mind, the motive whereof is not any intrinſic evidence, but the authority, or teſtimony, of ſome other, who reveals or relates it.

Hence, as there are two kinds of authorities and teſtimonies, the one of God, and the other of man, *faith* becomes diſtinguiſhed into *divine* and *human*.

FAITH, *divine*, is that founded on the authority of God; or it is that aſſent we give to what is revealed by God.

The objects of this *faith*, therefore, are matters of REVELATION.

FAITH, *human*, is that whereby we believe what is told us by men.

The object hereof is matter of human teſtimony and EVIDENCE.

Faith, again, may be diſtinguiſhed into *implicit*, and *ſcientific*.

FAITH, *implicit*, or *blind*, is that whereby we give our aſſent to a propoſition advanced by another, of whoſe knowledge and veracity we have no certain and evident reaſon, or proof. This is only opinion, under another name.

FAITH, *ſcientifical*, or *ſcient*, is that by which we give our aſſent to a propoſition advanced by one who can neither deceive, nor be deceived; which may be properly referred to ſcience and knowledge.

Divine faith, ſuperi poribus, is ſtronger than human. When we are fully convinced, that any propoſition comes from God, *faith* becomes aſſurance, or ſcience; ſo being an ingredient in our idea of God, that he can neither deceive, nor be deceived; but when there is any doubt, whether the propoſition is declared by God, the *faith* can be no ſtronger, or weaker, then the reaſons on which it is founded; divine *faith*, therefore, may either be ſtrong, weak, or none at all. Again the reaſons or motives of believing men, may be of ſuch weight and force, that being perfectly underſtood, they may equal a mathematical evidence; and then the human *faith* is ſcarce inferior to the divine; there being, as it were, an equal neceſſity of giving our aſſent on each ſide.

Hence it is eaſily obſerved, that all our *faith* or belief has its foundation on reaſon, which cannot deceive us, if we make a due uſe of our liberty, and do not acquieſce, till that neceſſarily compels us.

All our preſent religious *faith* is really human, as depending on the ſecondary teſtimony of men; of whoſe veracity, however, we have the ſtrongeſt proofs. The prophets, or thoſe to whom God immediately revealed his will, believed him becauſe they knew he could not deceive. We, at this day, believe them, or rather their writings, for other reaſons; viz. the ſame which oblige us to believe all well-atteſted hiſtories. See EVIDENCE.

Beſides the two ſpecies of *faith*, human and divine, the Romaniſts make a third, or intermediate kind, called

FAITH, *eccleſiaſtical*, which is the aſſent orthodox perſons give to certain events decided by the church, and enjoined to be believed by all.

As, when the church declares, that ſuch a book contains heretical doctrine, &c.

This term, *eccleſiaſtical faith*, was introduced by M. Pereſixe, to diſtinguiſh the faith whereby we believe matters of divine revelation, from that whereby we believe matters of eccleſiaſtical tradition.

FAITH, in *Practical Theology*, or as it is the firſt of the theological virtues, or graces.

Faith in God, in this ſenſe, denotes ſuch a conviction of his being, perfections, character, and government, as produces love, truſt, worſhip, obedience, and reſignation.

Faith in Chriſt, as it has been defined by ſome, is a mere aſſent to the Goſpel as true; according to others, it ſignifies ſuch a perſuaſion that he is the Meſſiah, and ſuch a deſire and expectation of the bleſſings which he has promiſed in his Goſpel to his ſincere diſciples, as engage the mind to fix its dependence upon him, and ſubject itſelf to him in all the ways of holy obedience; and thus defined it is a very extenſive principle, and includes in its nature and inſeparable effects the whole of moral virtue. In this ſenſe it has been ſaid, that under the Goſpel a man is juſtified by *faith*. *Faith*, likewiſe, in reſpect to futurity, is a moral principle, implying ſuch a conviction of the reality and importance of a future ſtate, as is ſufficient to regulate the temper and conduct.

FAITH, *confeſſion of*. See CONFESSION.

FAITH and *homage*, in the *Feudal Law*. See FEALTY.

FAITHFUL, an appellation which the Mahometans aſſume to themſelves. See MUSSULMAN.

FAITHFULNESS, in *Ethics*, is an agreement between a man's promiſes and his actions.

FAITIERE, in *Natural Hiſtory*, the name of a ſpecies of ſhell-fiſh, called by many authors, by a much leſs determinate name, *concha imbricata*. The French have thus called it, from the word *faitage*, which, in the ſame language, ſignifies the *roof of a houſe*. The ſhell is of the buccinidium, or ox-heart kind, and has ſeven longitudinal rows, and a great many tranſverſe running tranſverſely acroſs them, ſo that it greatly reſembles the roof of a houſe, where the rafters and croſs-beams are ſeen while it is not covered with tiles.

FAITOURS is uſed in ſtat. 7 Ric. II. cap. 5. for evil doers; and may be interpreted idle livers, from (ſays the author of the Termes de Ley) *faitardiſe*, which ſignifies a kind of ſleepy diſeaſe, proceeding from too much ſluggiſhneſs. In the formentioned ſtatute it ſeems ſynonymous with vagabond.

FAKE, or FACK, in the *Sea Language*, one round or circle of a cable; otherwiſe called a coil.

FAKIR, or FAQUIR, a kind of derviſe, or Mahometan religious, who travels the country, and lives on alms.

The word *fakir* in Arabic, and ſignifies a *poor* or *needy perſon*. It is formed of the word فقر, *fachara*, *to be in need*.

D'Herbelot makes *fakir* and derviſe the ſame thing. The Turks and Perſians uſe the name derviſe for any poor perſon, whether he be ſo out of neceſſity or choice; and the Arabs apply *fakir* in the ſame ſenſe. Whence, in ſome

some Mahometan countries, the religious are called *dervises*; and in others, particularly throughout the states of the great Mogul, *fakirs*.

The *fakirs* sometimes travel singly, and sometimes in companies. When they go in companies, they have a superior, who is distinguished by his habit. Each *fakir* begrs a horn, which he blows at his arrival in any place, as also at his departure; and a kind of scraper or trowel, to scrape the earth in the place where he sits, or lies down. When they go together, they divide their alms equally amongst them; give what is left every night to the poor; and never reserve any thing for the morrow.

There is also a kind of idolatrous *fakirs*, who follow much the same practice. D'Herbelot reckons in the Indies eight hundred thousand Mahometan *fakirs*, and twelve hundred thousand idolatrous ones; to say nothing of divers extraordinary species of *fakirs*, particularly penitents, whose mortification and penance consist in very odd observances. Some, e. gr. remain night and day, for many years, in certain uneasy postures. Others never sit or lie down to sleep, but sustain themselves by a rope, hung down for that purpose. Others bury themselves in a ditch, or pit, for nine or ten days, without eating or drinking. Others keep their arms lifted up to heaven, so long, till they cannot let them down again if they would. Others lay fire on their heads, and burn the scalp to the very bone. Others roll themselves naked on thorns. Tavernier, &c.

Another class of *fakirs* retire into mosques, live on alms and devote themselves to the study of the law, the reading of the Alcoran, &c. to fit themselves for moulas, or doctors. People of quality sometimes assume the character of *fakirs*. The famous Aurengzeb himself, before he ascended the throne, gave out, that he intended to commence *fakir*.

FALACA, a kind of bullinado inflicted on the Christian captives in Algiers. The *falaca* is properly a piece of wood, about five feet long, bored with two holes, through which the feet of the patient are put, who is laid on his back on the ground, with his arms tied. Two men are employed to give him fifty or a hundred strokes with a cudgel, or bull's pizzle, on the soles of his feet. A very trifling fault often incurs this severe punishment.

FALACER, in *Mythology*, the name of a Roman deity, recorded by Varro.

FALANG, in our *Old Writers*, is used for a jacket or close coat. Blount.

FALANGIE, in the *Materia Medica*, a name given by some of the ancients to the ocymum or basil. The *falangie mosk* is the sweet-scented basil. Some of the commentators on the works of Avicenna, have supposed, that the fruit called sel, was the seed or fruit of this plant; and that the word was only an abbreviation of *falangie*, but this is by no means right. See FEL.

FALCADE, in the *Manege*. A horse makes *falcades*, when he throws himself upon his haunches two or three times, as in very quick curvets, which is done in forming a stop, and half-stop. A *falcade*, therefore, is the action of the haunches, and of the legs, which bend very low, as in curvets, when you make a stop or half stop.

They say, this horse stops well, for he makes two or three *falcades*, and finishes his stop with a pesate. This horse has no haunches, he will make no *falcades*. The *falcades* are so much the prettier, as in making them his haunches are low. Stop your horse upon the haunches, in making him ply them well, so that after forming his *falcades*, he may resume his gallop without making a pesate, that is, without stopping, or making one time. And thus he will make an half STOP. See HAUNCHES and TIME.

FALCANOS, a name given by some of the chemical writers to arsenic.

FALCATA, in our *Old Writers*, was used for the grass fresh mowed, and laid in swathes.

FALCATED, one of the phases of the planets, popularly called horned.
